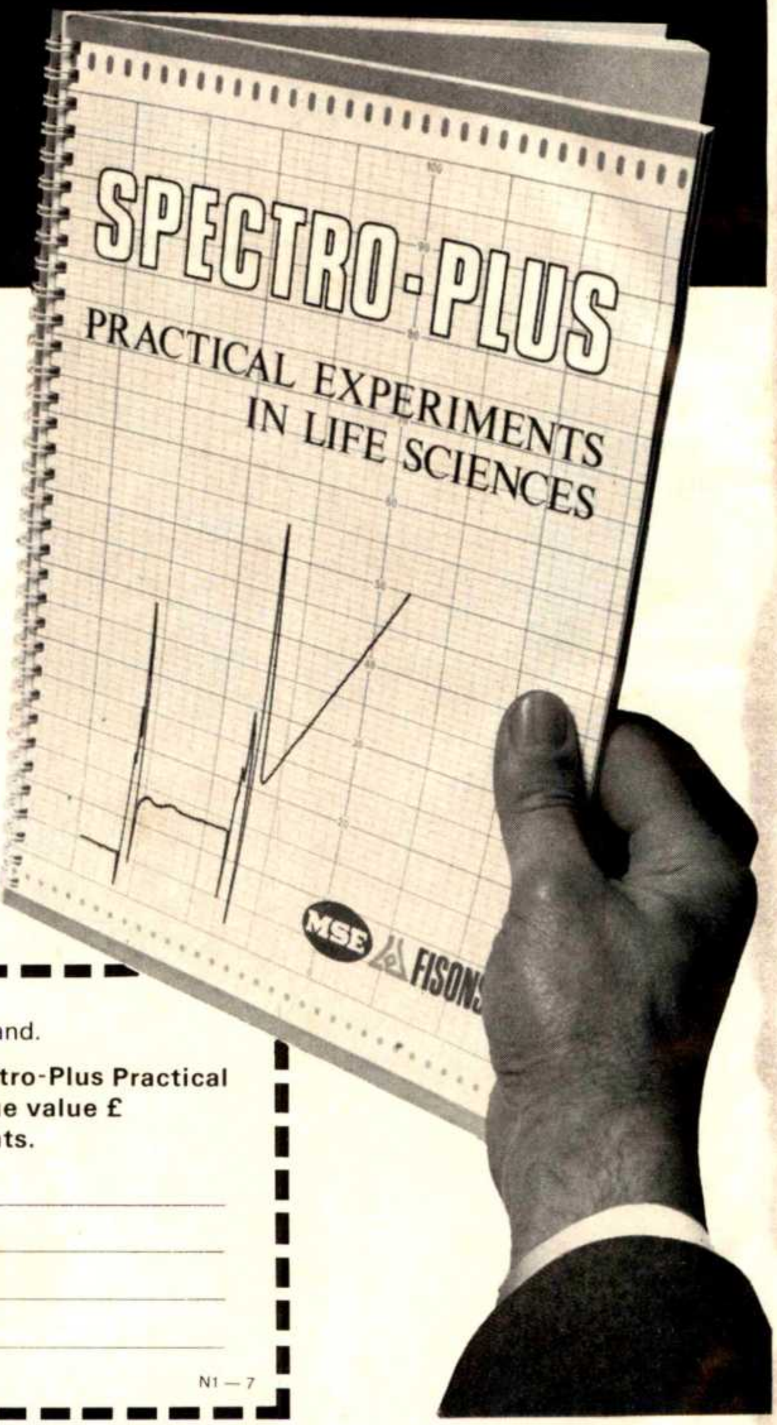
This manual contains a collection of experiments in

- **SPECTROPHOTOMETRY** • **FLUORIMETRY**
- **pH MEASUREMENT** • **DISSOLVED OXYGEN MEASUREMENT** carried out with a single instrument –

SPECTRO-PLUS



Spectro-Plus is a versatile multifunctional instrument with applications chiefly in life science related laboratories. As a tool for teaching in practical courses at universities and technical colleges its cost effectiveness is unmatched by any other device. As a UV spectrophotometer it is competitively priced; hence fluorescence, pH and oxygen measurements are gratuitous extras. Use the coupon below, send for the Spectro-Plus manual and see for yourself what is possible with this unique instrument.

The book contains an accurate record of experimental data from 25 experiments covering the four modes of Spectro-Plus.

It is of substantial general interest and although designed to assist every Spectro-Plus user it can stand on its own merits as a textbook of practical biochemistry.

Copies are available direct from MSE, price £3 each, post free.

To **MSE Scientific Instruments,**
Manor Royal, Crawley, West Sussex, England.

Please send me ☐ copies of the Spectro-Plus Practical Experiments Manual. I enclose cheque value £ made out to MSE Scientific Instruments.

Pure Chemistry Library
SCIENCE COLLEGE

Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words

Manuscripts may be submitted either to London or Washington Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) To refer to several references by the same author at once, only one reference number need be given.

(ii) Cite first and last pages.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number Line drawings to be in Indian ink on heavy cartridge paper, tracing paper or similar materials: thin, shiny, torn or folded material should be avoided. Scales for graphs should be chosen such that simple figures will not occupy an inordinate amount of space Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text they should contain only essential material. Ideally, an unlabelled original and a labelled copy should be provided: labelling on photographs should, if possible, be avoided entirely. Records, charts etc. which will not reproduce well should be redrawn or simply described in the text. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Down's syndrome and related abnormalities in an area of high background radiation in coastal Kerala — *N. Kochupillai, I. C. Verma, M. S. Grewal and V. Ramalingaswami* 60
Modulation of the synthesis *in vitro* of a hormone-induced protein by transfer RNA — *O. K. Sharma, D. N Beezley and E. Borek* 62
Human-mouse cell hybrid with human multiple Y chromosomes — *R Tantravahi, V G. Dev, D. A. Miller and O J. Miller* 63
Chromosomal proteins regulate steroid binding to chromatin — *T C. Spelsberg, R A Webster and G. M. Pikler* 65
Effect of maternal age on intercellular adhesion of embryonic chick liver cells — *J. Umbreit and S. Roseman* 67
Limited proliferation of stem cells surviving alkylating agents — *L. E. Botnick, E. C. Hannon and S. Hellman* 68
Transformation of the β_2 adrenoreceptor in normal rat liver into a β_1 type in Zajdela hepatoma — *M-L. Lacombe, E. Rene, G. Guellaen and J. Hanoune* 70
Effect of restriction endonucleases on infectivity of Rous sarcoma virus DNA — *H. Kopecka, J Hillova and M. Hill* 72
Spontaneous transformation of human skin fibroblasts derived from neoplastic patients — *B. Azzarone, D. Pedulla and C. A. Romanzi* 74
Enumeration of specific cytotoxic T cells — *R. M. Thorn and C. S. Henney* 75
Enhancement of delayed hypersensitivity by depletion of suppressor T cells with cyclophosphamide in mice — *A. Mitsuoka, M Baba and S. Morikawa* 77

NEWS AND VIEWS

Chandler wobble/Palindromic DNA/Genetic engineering/Manganese/Q$_\beta$ replicase/Enzymes 254

ARTICLES

Excitation of the Chandler wobble by large earthquakes — *R. J. O'Connell and A. M. Dziewonski* 259
Possible evidence for penetration of interstellar dust into the Solar System — *J. L. Bertaux and J. E. Blamont* 263
Neutron diffraction studies of retinal rod outer segment membranes — *H. Saibil, M. Chabre and D. Worcester* 266

LETTERS TO NATURE

On being close to a black hole without falling in — *R. Znajek* 270
Outbursts of the recurrent nova T Coronae Borealis — *R. F. Webbink* 271
A plum-pudding model for interstellar grains — *S. Simons and I. P. Williams* 273
A comparison of acoustic Doppler vertical velocities with direct measurements in the atmospheric boundary layer — *S. J. Caughey, B. A. Crease, D. N. Asimakopoulos and R. S. Cole* 274
Hercynian high pressure/low temperature metamorphism in the Ile de Groix Blueschists — *M. S. N. Carpenter and L. Civetta* 276
'Space' charging of insulators — *D. K. Davies* 277
Charges and vacuum flashover — *D. K. Davies* 279
Aspartic acid racemisation in dentine as a measure of ageing — *P. M. Helfman and J. L. Bada* 279
Sun and shade differences in productivity of reef corals — *D. S. Wethey and J. W. Porter* 281
Frost sensitivity of *Zea mays* increased by application of *Pseudomonas syringae* — *D. C. Arny, S. E. Lindow and C. D. Upper* 282
Fog basking by the Namib Desert beetle, *Onymacris unguicularis* — *W. J. Hamilton, III and M. K. Seely* 284
Nucleating agents in the haemolymph of insects tolerant to freezing — *K. E. Zachariassen and H. T. Hammel* 285
Induction of male recombination in *Drosophila melanogaster* by injection of extracts of flies showing male recombination — *J. H. M. Sochacka and R. C. Woodruff* 287
Initiation of meiotic maturation in *Xenopus laevis* oocytes by lanthanum — *S. Schorderet-Slatkine, M. Schorderet and E.-E. Baulieu* 289
Benzpyrene induces sister chromatid exchanges in cultured human lymphocytes — *H. W. Rüdiger, F. Kohl, W. Mangels, P. von Wichert, C. R. Bartram, W. Wöhler and E. Passarge* 290
Expression of maternal and paternal antigens on trophoblast — *J. Carter* 292
Successful induction of specific tolerance to transplantation antigens using autoimmunisation against the recipient's own natural antibodies — *H. Binz and H. Wigzell* 294
Induction of transplantation tolerance using serum as antigen source — *M. Hašek, J. Chutná, V. Holáň and M. Sládeček* 295
Antibody response induced *in vitro* to the cell-surface alloantigen Thy-1 — *P. Lake* 297
Transition probability and the hormonal and density-dependent regulation of cell proliferation — *J. H. Robinson, J. A. Smith, N. F. Totty and P. N. Riddle* 298
Identification of the cell multiplication inhibitory factors in interferon preparations as interferons — *W. E. Stewart, II, I. Gresser, M. G. Tovey, M.-T. Bandu and S. Le Goff* 300

Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) To refer to several references by the same author at once, only one reference number need be given.

(ii) Cite first and last pages.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings to be in Indian ink on heavy cartridge paper, tracing paper or similar materials: thin, shiny, torn or folded material should be avoided. Scales for graphs should be chosen such that simple figures will not occupy an inordinate amount of space. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text they should contain only essential material. Ideally, an unlabelled original and a labelled copy should be provided: labelling on photographs should, if possible, be avoided entirely. Records, charts etc. which will not reproduce well should be redrawn or simply described in the text. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Antiviral and cell growth inhibitory activities reside in the same glycoprotein of human fibroblast interferon — *E. Knight, Jr* 302
Direct measurement of membrane motion and fluidity by electron microscopy — *S. W. Hui* 303
Potentiation of central reward by localised perfusion of acetylocholine and 5-hydroxytryptamine — *P. Redgrave and R. I. Horrell* 305
Stimulation of cerebral histamine H_2 receptors by clonidine — *Y. Audigier, A Virion and J.-C. Schwartz* 307
Synaptic vesicle cytochemistry changes when cultured sympathetic neurones develop cholinergic interactions — *M. Johnson, D. Ross, M. Meyers, R. Rees, R. Bunge, E. Wakshull and H. Burton* 308
Enkephalin regulates the levels of cyclic nucleotides in neuroblastoma × glioma hybrid cells — *M. Brandt, R. J. Gullis, K. Fischer, C. Buchen, B. Hamprecht, L. Moroder and E. Wunsch* 311
Enkephalin and opiate narcotics increase cyclic GMP accumulation in slices of rat neostriatum — *K. P. Minneman and L. L. Iversen* 313
A sequential *in vivo–in vitro* study of carcinogenesis induced in the rat brain by ethylnitrosourea — *J. P. Roscoe and P. J. Claisse* 314
Native collagen formation by liver parenchymal cells in culture — *K. Sakakibara, M. Saito, M. Umeda, K. Enaka and Y. Tsukada* 316
Identification of medicarpin as a phytoalexin in the broad bean plant (*Vicia faba* L.) — *J. A. Hargreaves, J. W. Mansfield and D. T. Coxon* 318
Initiation inhibition and reinitiation of the synthesis of heterogeneous nuclear RNA in living cells — *E. Egyházi* 319
Inactivation of parathyroid hormone mRNA by treatment with periodate and aniline — *B. Kemper* 321
Aqueous glasses as matrices in freeze-fracture electron microscopy — *F. Franks and H. le B. Skaer* 323
The hinge-bending mode in lysozyme — *J. A. McCammon, B. R. Gelin, M. Karplus and P. G. Wolynes* 325
Structure of bilirubin — *R. Bonnett, J. E. Davies and M. B. Hursthouse* 326
Erratum 328

Matters arising

Deposit-forming by zinc dithiophosphates in base oils during oxidation — *H. B. Silver* 329
Haemoglobin type and superovulation in ewes — *A. O. Trounson, S. M. Willadsen, R. M. Moor and E. M. Tucker* 329
Volcanic triggering of glaciation — *P. W. Francis* 329
Reply — *J. R. Bray* 330
Acoustic Bragg diffraction from human tissues — *R. C. Chivers* 330
Reply — *D. Nicholas and C. R. Hill* 330

Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) To refer to several references by the same author at once, only one reference number need be given.

(ii) Cite first and last pages.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings to be in Indian ink on heavy cartridge paper, tracing paper or similar materials: thin, shiny, torn or folded material should be avoided. Scales for graphs should be chosen such that simple figures will not occupy an inordinate amount of space. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text they should contain only essential material. Ideally, an unlabelled original and a labelled copy should be provided: labelling on photographs should, if possible, be avoided entirely. Records, charts etc. which will not reproduce well should be redrawn or simply described in the text. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

REVIEW ARTICLE

Fundamental research in molecular biology: relevance to medicine *M. F. Perutz* 449

ARTICLES

Seeing order in 'amorphous' materials *O. L. Krivanek, P. H. Gaskell and A. Howie* 454
Isotropic cosmic expansion and the Rubin–Ford effect *S. M. Fall and B. J. T. Jones* 457
Fossil hominids from the Laetolil Beds *M. D. Leakey, R. L. Hay, G. H. Curtis, R. E. Drake, M K. Jackes and T. D. White* 460
Non-genetic individuality: chance in the single cell *J. L. Spudich and D E. Koshland, Jr* 467

LETTERS TO NATURE

Observations of X-ray and γ bursts *J. J. Quenby, M. J Coe, A R. Engel and J. S. Mills* 471
Positions and evidence for a steady component for X-ray burst sources *G. F Carpenter, G. K Skinner, A. M. Wilson and A. P. Willmore* 473
Observations of X-ray bursts from the vicinity of 3U1727—33 *K. O. Mason, S. J. Bell-Burnell and N. E. White* 474
The radio tail galaxies in Abell 1314 *G. D. Coleman, P. Hintzen, J S. Scott and M Tarenghi* 476
White dwarfs, the Galaxy and Dirac's cosmology *R. Stothers* 477
Extraction of metals from basalt by humic acids *A Singer and J. Navrot* 479
Climatic information from $^{18}O/^{16}O$ ratios of cellulose in tree rings *J. Gray and P. Thompson* 481
Geometry of river meanders *R. D. Hey* 482
New hominid from Lake Ndutu, Tanzania *A. A. Mturi* 484
New cranium of *Homo erectus* from Lake Ndutu, Tanzania *R. J. Clark* 485
Antennal receptor response to sex pheromone mimics in the American cockroach *H. Washio, C Nishino and W S. Bowers* 487
Ecdysone and oocyte morphogenesis in *Bombyx mori* *J.-M. Legay, B. Calvez, M. Hirn and M. L. De Reggi* 489
Covering response in sea urchins *J. M. Lawrence* 490
Testing the neutral mutation hypothesis by distribution of single locus heterozygosity *M. Nei, P. A. Fuerst and R. Chakraborty* 491
Y chromosome visibility in quinacrine-stained human spermatozoa *A. M Roberts and H Goodall* 493
Absence of axonemal arms in nasal mucosa cilia in Kartagener's syndrome *H. Pedersen and N. Mygind* 494
Separation of suppressor and killer T cells by surface phenotype *P. C. L. Beverley, J. Woody, M. Dunkley, M. Feldmann and I McKenzie* 495
Plasma membrane glycoprotein which mediates adhesion of fibroblasts to collagen *E. Pearlstein* 497
Temporary intestinal hypoxia induced by degradable microspheres *K. E. Arfors, J. O Forsberg, B. Larsson, D. H. Lewis, B. Rosengren and S. Odman* 500

[illegible]

Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) To refer to several references by the same author at once, only one reference number need be given

(ii) Cite first and last pages

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65) Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings to be in Indian ink on heavy cartridge paper, tracing paper or similar materials: thin, shiny, torn or folded material should be avoided. Scales for graphs should be chosen such that simple figures will not occupy an inordinate amount of space. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text they should contain only essential material. Ideally, an unlabelled original and a labelled copy should be provided: labelling on photographs should, if possible, be avoided entirely. Records, charts etc. which will not reproduce well should be redrawn or simply described in the text. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Metabolic adaptation to pregnancy shown by increased biosynthesis of insulin in islets of Langerhans isolated from pregnant rats — *A. J. Bone and K. W. Taylor* 501
Electrophysiological evidence for coupling between β cells of pancreatic islets — *H. P. Meissner* 502
Decrease of Na^+ conductance during desensitisation of the frog endplate — *K. Kuba and K. Koketsu* 504
Elevated levels of enkephalin in morphine-dependent rats — *R. Simantov and S. H. Snyder* 505
Prolactin suppresses releases of luteinising hormone during lactation in the monkey — *R. Maneckjee, B. R. Srinath and N. R. Moudgal* 507
Bacteria necessary to produce experimental autoimmune myasthenia gravis in acetylcholine receptor-immunised rabbits? — *E. Heilbronn, C. Mattsson and E. Stålberg* 509
Cyclic AMP and cyclic GMP may play opposing roles in influencing force of contraction in mammalian myocardium — *H. Nawrath* 509
Opposing effects of cyclic AMP and cyclic GMP on protein phosphorylation in tubulin preparations — *I. V. Sandoval and P. Cuatrecasas* 511
Structural properties of rat serum proteins which correlate with their degradative rates *in vivo* — *J. F. Dice and A. L. Goldberg* 514
Accessibility of DNA in condensed chromatin to nuclease digestion — *C. J. Bostock, S. Christie and F. T. Hatch* 516
Amphipathic enzyme–polymer conjugates — *R. A. G. Smith* 519

BOOK REVIEWS

Malnutrition and Brain Development (Myron Winick)—*John Dobbing* 521
Nutrition and the Developing Nervous System (Philip R. Dodge, Arthur L. Prensky and Ralph D. Feigin)—*John Dobbing* 521
Polymeric Carbons: Carbon Fibre, Glass and Char (G. M. Jenkins and K. Kawamura)—*Paul Calvert* 521
Landmark Experiments in Twentieth Century Physics (George L. Trigg)—*R. Latham* 522
The Nucleon-Nucleon Interaction (G. E. Brown and A. D. Jackson)—*Leonardo Castillejo* 522
Pioneers in Neuroendocrinology (Joseph Meites, Bernard T. Donovan and Samuel M. McCann, editors)—*Barend ter Haar* 523
Climate and Environment: The Atmospheric Impact on Man (John F. Griffiths)—*John Gribbin* 523

Single ionic channels induced in lipid bilayers by polyene antibiotics amphotericin B and nystatine	*L. N. Ermishkin, Kh. M. Kasumov and V. M. Potzeluyev*	698

Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) To refer to several references by the same author at once, only one reference number need be given.

(ii) Cite first and last pages.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings to be in Indian ink on heavy cartridge paper, tracing paper or similar materials: thin, shiny, torn or folded material should be avoided. Scales for graphs should be chosen such that simple figures will not occupy an inordinate amount of space. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text they should contain only essential material. Ideally, an unlabelled original and a labelled copy should be provided: labelling on photographs should, if possible, be avoided entirely. Records, charts etc. which will not reproduce well should be redrawn or simply described in the text. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) To refer to several references by the same author at once, only one reference number need be given.

(ii) Cite first and last pages.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings to be in Indian ink on heavy cartridge paper, tracing paper or similar materials: thin, shiny, torn or folded material should be avoided. Scales for graphs should be chosen such that simple figures will not occupy an inordinate amount of space. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text they should contain only essential material. Ideally, an unlabelled original and a labelled copy should be provided: labelling on photographs should, if possible, be avoided entirely. Records, charts etc. which will not reproduce well should be redrawn or simply described in the text. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Too narrow-minded about energy?

THE gilt text inscribed around the ceiling of Church House, Westminster, speaks of "true light", "lending radiance" and "enduring in the heat" (admittedly "of the conflict"). A highly appropriate setting for Mr Anthony Wedgwood Benn's National Energy Conference last week, to which 470 were invited and at which 56 spoke.

Let it first be said that all those reasonable doubts that such an event could take place without degenerating into a shambles turned out to be unjustified, for which great credit to Mr Benn's chairmanship (and not least his restraint in not intervening in the debate at all himself) and to the speakers who never once exceeded their time limit But there is a world of difference between a well-ordered debate and open government; has Mr Benn done anything beyond ensure that all interested parties had a six-minute airing of the views?

There is no doubt the meeting was valuable in mutual education terms; almost all attenders had at least the courtesy to sit and listen to all contributions rather than break up into factions in the corridor to discuss heaven knows what. But what can Mr Benn and his staff do as a result of it all that he couldn't have done the day before?—for it can reasonably be assumed that he, as an exponent of open government, will have been familiar with all the points raised—even Sir Brian Flowers warning that the Royal Commission on Environmental Pollution will raise serious questions about living with plutonium, and even Mr Enoch Powell's brilliant oratory against any form of energy policy-making as ill-conceived and pernicious.

That Mr Benn and his department will have learnt little new from his conference is really the result of attempting to get too many things in focus in one day. The most incongruous of them was the question of disconnections of electricity and gas for non-payment. This was a bandwagon tailor-made for union leaders to jump on to, and although it provided some stirring talk, it managed to confuse a conference convened to talk about energy policy by diverting attention to matters of social policy, which should not be within Mr Benn's terms of reference.

Another structural weakness of the day was the lack of a challenging position paper. Before the conference everyone had been flooded with documents representing the positions of every conceivable interest, but the Department of Energy had, it seemed, decided to maintain a low profile. Its agenda and discussion paper was little more than a list of subject headings—and even that was largely ignored by speakers.

In hindsight, this was probably unfortunate. What was really needed was a major presentation, perhaps an hour in length and certainly well illustrated (not a slide was shown all day!), skilfully aimed at raising the more provocative issues and setting a more definite tone for the day. Perhaps Mr Benn will try this, as he undoubtedly has plans for future, smaller gatherings.

But whatever the next move is that Mr Benn has up his sleeve, his eventual plans for the gas industry are likely to provide the most sensitive litmus of true commitment to "open government". When Lord Ryder stood up to dismiss as economically senselesss the calls for a competitive restrictive tariff on North Sea gas, he was not only supporting the gas industry itself, but also voicing the majority opinion among institutionally disinterested energy experts. Lord Ryder's reference to a 1976 version of the mad hatter's tea party, and his warning of the dangers of a "wretched cartel with coal and electricity" will ensure one thing at least. If Mr Benn, often accused of a fondness for dogmatism, eventually opts for the recommendations of his political advisers and thus weighs down the nation's only economically sound energy industry, he will need a convincing case to defend himself against allegations of blind adherence to doctrine. While some sympathy must be felt for the coal and electricity chiefs, struggling through a difficult period, on current analyses a gas tax provides a poor solution to their own dilemma, and a poorer answer to the nation's broader, long-term energy problems.

The difficulties of the gas industry perhaps underline a disturbing thread running through the day (and conceivably the result of no strong position paper) the narrow-mindedness of most participants. An unspoken assumption seemed to be that self-sufficiency in Britain was the aim and if we talked about energy in any international forum at all (and almost all didn't) it was to be from a position of independence This was the much more explicit objective, two years ago, of Project Independence in the United States. It assumes that in the long run no foreigners are trustworthy. There is much danger in such chauvinism, which may go down well in some political circles but which could lead to some ridiculously expensive decisions being made in pursuit of xenophobia.

Britain in general depends heavily on importing and exporting and is inevitably vulnerable to the capriciousness of suppliers of raw materials and food. But foreign policy, recognising no alternative to large-scale importing, is aimed at maintaining the appropriate good relations Should energy be an exception to be protected by vast expenditures in research, development and implementation? This is one issue we would like to hear Mr Benn speak more of. □

Genetic manipulation: guidelines issued

The NIH ground rules for genetic manipulation experiments may not mark the end of an unprecedented debate within the scientific community. **Colin Norman** reports from Washington

AFTER two years of controversy and uncertainty, the National Institutes of Health (NIH) last week issued a complex set of guidelines governing the use of a powerful new technique for manipulating genes in living organisms. The guidelines establish safety rules for experiments which may revolutionize biology, but which also provide man with unprecedented ability to alter the characteristics of living things. They are, however, far from being the final word on whether, and under what circumstances, such research should be allowed to go ahead, for they are already being overtaken by events in some places.

On July 7, for example, the City Council in Cambridge, Mass., will vote on a resolution, proposed by the Mayor, which would ban for two years all such experiments at Harvard and MIT. And months of bitter debate at the University of Michigan have resulted in the adoption of regulations there which are more strict than those issued by NIH last week. The focus of the debate is clearly shifting from Washington into the university communities where the research will take place.

Nevertheless, the NIH guidelines will provide important ground rules for genetic manipulation experiments in many institutions, and their impact will extend far beyond the borders of the United States, for they are likely to influence the establishment of guidelines in many other countries. They have been developed by an extraordinary process of self-regulation by the scientific community.

The process began in 1973, when scientists familiar with the nascent technique began to worry about potential hazards associated with its use Their concerns led a committee of the National Academy of Sciences to issue a public statement in July 1974, urging scientists around the world to defer two types of experiments until the hazards have been defined The moratorium lasted until last February, when it was partly replaced by general guidelines recommended by an international group of geneticists which met at Asilomar, California Then an NIH advisory committee, consisting of scientists, took centre stage It laboured hard during most of last year trying to cast the Asilomar guidelines into more specific rules, completing its task by hammering out a set of complex proposals last December The proposals went to NIH Director Donald S. Fredrickson, who called a public meeting to discuss them, solicited the views of numerous scientists and non-scientists, and asked the advisory committee to reconsider some of its suggestions. The guidelines issued last week represent Fredrickson's distillation of the conflicting advice presented to him

They differ a little in detail, but not in philosophy, from the recommendations of the advisory committee. They will allow most planned experiments to go ahead, albeit under strict safety controls, outlawing only a handful of the more hazardous types of experiments They are, however, stricter than the Asilomar guidelines, a fact which Fredrickson suggested means that "the research will go forward in a manner responsive and appropriate to hazards that may be realised in the future". And Dr DeWitt Stetten, Deputy NIH Director for Science and chairman of the advisory committee, argued last week that "the issuance of the guidelines is in no sense an opening of the floodgates, rather it is a closing of the leaks (in the Asilomar guidelines)".

Be that as it may, the guidelines are not even NIH's final say on the matter. Their publication falls under the terms of the National Environmental Policy Act, which means that NIH must prepare an assessment of the potential impact of the research on the environment A draft assessment should be ready by September, and since it will be opened up for public comments before being cast in final form, another round of discussion of the risks and benefits of the research is in store. In the meantime, the guidelines will take effect, governing NIH's support of the research.

New dimension

Why have the guidelines taken so long to produce, and caused so much strife? The answer is that the research offers a spectacular mix of potential benefits and possible hazards, and it opens up an entirely new dimension in biology. The experiments consist, in short, of snipping genes from the DNA of any organism and splicing them into the DNA of another, perhaps entirely unrelated, organism. The resulting molecule—a recombinant DNA molecule—is copied (cloned) each time the new host reproduces, producing large quantities of the transplanted genes. The technique offers a powerful tool for probing the working of genes and their arrangement in complex organisms and, more distantly, it may offer a means of constructing special micro-organisms for a variety of medical, commercial and industrial uses.

But the worry is that the technique allows biologists to breach genetic barriers between species which have evolved over thousands of years. In short, it allows biologists to by-pass the processes of evolution. More specifically, foreign genes inserted into an organism may cause that organism to behave in a dangerous, and perhaps unpredictable, manner. The guidelines thus seek to ensure that micro-organisms bearing transplanted genes are contained in the laboratory.

They spell out our levels of physical containment to be used in such experiments, designated P1 to P4, ranging from use of standard microbiological techniques (P1) to the use of specially equipped facilities akin to biological warfare laboratories (P4). And, as a second line of defence, they spell out three levels of biological containment, EK1 to EK3, which must be used for experiments involving the insertion of genes into a strain of the common gut bacterium *E. coli*—the organism which will be used for most experiments. The levels are as follows:

- EK1—use of standard *E. coli* K12, a laboratory strain of *E. coli* which has been used for genetic experiments for decades Foreign genes are inserted into the bacterium by splicing them into a plasmid (a ring of bacterial DNA which reproduces independently from the bacterium's chromosomes) and reintroducing the recombinant into the bacterium, or by splicing them into the DNA of a bacteriophage which then infects *E. coli* K12.

- EK2—the use of specially mutated strains of *E. coli* or bacteriophage which, according to laboratory tests, are virtually incapable of surviving outside the laboratory so that the recombinant DNA will have less than 1 in 10^{-8} chances of surviving in the natural environment.

- EK3—the same as EK2 except that the survivability has been tested in animals, plants and other environments.

The guidelines assign specific physical and biological safety levels to various types of experiments on the basis of their potential hazards (see box) They also spell out safety rules for experiments involving recombinants formed by splicing genes into the DNA of animal viruses, which are then grown in cell cultures to provide multiple copies of the foreign genes. The final guidelines alter some of the containment levels proposed by the advisory committee, but no substantial alterations have been made.

Cautious approach

How did Fredrickson arrive at his final decision when confronted with such a wealth of conflicting advice? His first, and most fundamental, consideration was simply whether the research should be allowed to go ahead at all, in view of the potential hazards The majority of the commentators on the guidelines recommended that it should, but he was advised to take an extremely cautious approach by two of the most eminent of the commentators, neither of whom intends to conduct experiments with recombinant DNA.

Dr Robert Sinsheimer, chairman of the Department of Biology at California Institute of Technology, argued in a letter to Fredrickson that the experiments present a serious hazard if they breach the genetic barrier between higher organisms (eukaryotes) and lower organisms (prokaryotes). "One need not continue to spin out potential horror stories", he wrote, "the point is that we will be perturbing, in a major way, an extremely intricate ecological interaction which we understand only dimly". As for the guidelines themselves, Sinsheimer stated: "I cannot believe that under these proposed guidelines the organism can be contained. If the work is going on in a hundred laboratories about the United States, performed by technicians, graduate students, etc.; the organism will inevitably escape—and will enter into the various ecological niches known to be inhabited by *E. coli.*" He therefore proposed that all work with recombinant DNA should be performed under maximum containment conditions at a single institution in the United States, and that there should be an intensive effort to seek a microorganism more suitable than *E. coli* for the work.

The other eminent, though more flamboyant, critic of the guidelines, Erwin Chargaff of Columbia University, recommended that all work on recombinant DNA should be halted for at least two years to allow time for the hazards to be assessed Chargaff asked, in a letter published in *Science*, "Have we the right to counteract, irreversibly, the evolutionary wisdom of millions of years, in order to satisfy the ambition and the curiosity of a few scientists?"

The advisory committee did not consider Sinsheimer's or Chargaff's pro-

Guidelines in detail

The guidelines define four levels of physical containment, designated, in order of increasing stringency, P1 to P4, and three levels of biological containment, EK1 to EK3, and assign experiments to them on the basis of potential risk. The following is a summary of containment levels specified for various sources of DNA.

a. Shotgun experiments using *E. coli* as the host

Non-embryonic primate tissue	P3+EK3 or P4+EK2
Embryonic primate tissue or germ line cells	P3+EK2
Other mammals	P3+EK2
Birds	P3+EK2
Cold blooded vertebrates, non-embryonic	P2+EK2
embryonic or germ line	P2+EK1
If vertebrate produces a toxin	P3+EK2
Other cold blooded animals and lower eukaryotes	P2+EK1
If Class 2 pathogen*, produces a toxin, or carries a pathogen	P3+EK2
Plants	P2+EK1
Prokaryotes that exchange genes with *E. coli*	
Class 1 agents (non-pathogens)	P1+EK1
Low risk pathogens (for example, enterobacteria)	P2+EK1
Moderate risk pathogens (for example, *S. typhi*)	P2+EK2
Higher risk pathogens	banned
Prokaryotes that do not exchange genes with *E. coli*	
Class 1 agents	P2+EK2 or P3+EK1
Class 2 agents (moderate risk pathogens)	P3+EK2
Higher pathogens	banned

In all above cases, if DNA is at least 99% pure before cloning and contains no harmful genes, either physical or biological containment levels can be reduced one step.

b. Cloning plasmid, bacteriophage and other virus genes in *E. coli*

Animal viruses	P4+EK2 or P3+EK3
If clones free from harmful regions	P3+EK2
Plant viruses	P3+EK1 or P2+EK2
99% pure organelle DNA, Primates	P3+EK1 or P2+EK2
other eukaryotes	P2+EK1
Impure organelle DNA: shotgun conditions apply.	
Plasmid or phage DNA from hosts that exchange genes with *E. coli*	
If plasmid or phage genome does not contain harmful genes or if DNA segment 99% pure and characterised	P1+EK1
Otherwise, shotgun conditions apply.	
Plasmids and phage from hosts which do not exchange genes with *E. coli*	
Shotgun conditions apply, unless minimal risk that recombinant will increase pathogenicity or ecological potential of the host, then	P2+EK2 or P3+EK1

NB. cDNAs synthesised *in vitro* from cellular or viral RNAs are included in above categories.

c. Animal virus vectors

Defective polyoma virus+DNA from non-pathogen	P3
Defective polyoma virus+DNA from Class 2 agent	P4
If cloned recombinant contains no harmful genes and host range of polyoma unaltered, reduce to	P3
Defective SV40+DNA from non-pathogens	P4
If inserted DNA is 99% pure segment of prokaryotic DNA lacking toxigenic genes, or a segment of eukaryotic DNA whose function has been established and which has previously been cloned in a prokaryotic host-vector system, and if infectivity of SV40 in human cells unaltered	P3
Defective SV40 lacking substantial section of the late region+DNA from non-pathogens, if no helper used and no virus particles produced	P3
Defective SV40+DNA from non-pathogen can be used to transform established lines of non-permissive cells under P3 provided no infectious particles produced. Rescue of SV40 from such cells requires	P4

d. Plant host-vector systems

P2 conditions can be approximated by insect-free greenhouses, sterilization of plant, pots, soil and runoff water, and use of standard microbiological practice.

P3 conditions require use of growth chambers under negative pressure and routine fumigation for insect control.

Otherwise, similar conditions to those prescribed for animal systems apply.

*Classes for pathogenic agents as defined by the Center for Disease Control.

posals during its public meetings, but Fredrickson alluded to them in a lengthy statement published along with the guidelines. Recognising that the breaching of genetic barriers might pose a hazard, Fredrickson nevertheless argued that the research can be controlled so that it is carried out safely. Noting that "the international scientific community . . . has indicated a desire to proceed with research in a conservative manner", and that "most of the considerable public commentary on the subject, while urging caution, has also favoured proceeding", Fredrickson pointed out that there is, in any case, no way to prohibit the research throughout the world. "There is," he added, "no reason to attempt it."

Having decided that there should be no flat proscription on the research, Fredrickson turned to some of the chief concerns raised by the critics of the guidelines. The most prominent concern arises from the fact that most work with recombinant DNA will take place with the *E. coli* K12 bacterium. Since *E. coli* is a common inhabitant of the human gut, many observers have considered it a dangerous choice for the research. In particular, a group of scientists from the Boston area urged that a different host for transplanted genes be developed, and that the use of *E. coli* be phased out as swiftly as possible.

Fredrickson argues, however, that since the bacterium has been used for decades as the geneticists' workhorse, there is extensive knowledge of its behaviour and, moreover, there is good evidence that it is unlikely to survive for long in the environment in competition with wild strains of *E. coli*. In other words, *E. coli* K12 itself provides a level of biological containment. "I believe that because of this experience, *E. coli* K12 will provide a host-vector system that is safer than other systems", Fredrickson argued, and he declined to set a limit on when it should be phased out of the research.

Another area of concern with the proposed guidelines centred on how they should be implemented, and that section has been extensively revised. The guidelines strictly apply only to research supported by NIH, and investigators must comply with them before they can receive a grant. Some commentators suggested that principal investigators be required to obtain informed consent from all laboratory personnel before proceeding with recombinant DNA experiments, but Fredrickson opted instead for a requirement that the investigators simply inform all laboratory workers of the real and potential hazards associated with the experiments.

The guidelines also require that each institution where recombinant DNA experiments will be conducted should establish a biohazards committee, to ensure that facilities meet specified requirements, training is adequate and so on. The advisory committee had firmly recommended that such committees should not be responsible for determining the containment conditions for specific experiments, but Fredrickson deleted that prohibition, leaving the matter up to individual institutions.

A final point concerning implementation which is clearly worrying many people is that the guidelines do not apply to industry. Early last month, however, Fredrickson briefed officials from various industries on the guidelines and received from them expressions of support for their intent and their general provisions. Some officials expressed reservations about specific items, however, such as the provision prohibiting large-scale experiments with recombinant DNA, and the Pharmaceutical Manufacturers' Association has decided to convene a committee to review whether the guidelines are applicable to the drug industry.

Effect of guidelines

Now that these guidelines have been issued, how do they affect academic scientists conducting, or hoping to conduct, recombinant DNA experiments? First, they specify that many experiments should use EK2 or EK3 biological containment, and until crippled micro-organisms which meet those criteria are available, such experiments should not be conducted. The advisory committee which drafted the guidelines is responsible for certifying whether crippled strains meet the criteria.

A strain of *E. coli* produced by Roy Curtiss of the University of Alabama (called χ1776) has been proposed as an EK2 system with two specific plasmids (pSC101 and Col El-*kan*). Curtiss, who has built many crippling mutations into the bacteria in an effort which took the best part of a year, has provided the committee with reams of data on its survivability. Last month, a subcommittee voted unanimously that the strain meets the EK2 specifications, and the full committee is expected to approve it in the next few weeks. That would pave the way for many experiments.

But a confusing situation has developed with respect to two other candidate EK2 strains. At its last meeting in April, the committee approved a strain of bacteriophage lambda, developed by Philip Leder of NIH as an EK2 strain. But a subcommittee which met last month to consider a second candidate strain, developed by Fred Blattner at the University of Wisconsin, was divided on a matter which affects both strains. In short, two subcommittee members refused to endorse the use of either phage as an EK2 system unless they are used in conjunction with crippled bacteria. The full committee will take up that thorny issue when it next meets in September. Curtiss's *E. coli* strain, incidentally, is resistant to infection by phage λ

Many of the objections and reservations which critics have levelled at the guidelines are now beginning to crop up in local debates in and around the universities where the research will be conducted. In that regard, the situation brewing in Cambridge, Mass., may be an indication of things to come It began quietly a few months ago, when some researchers at Harvard proposed that a laboratory, meeting P3 requirements, be established in the Harvard Biology Labs. The facility, which would cost some $350,000, would have involved converting some existing laboratory space, and the intent was to undertake a variety of work in it, including some recombinant DNA experiments.

The proposal met with opposition within Harvard, however, largely because the biology labs are old, infested with cockroaches and with a species of ant which has so far evaded attempts at eradication. In short, critics suggested that the building is unsuitable for a P3 facility. Their criticisms broadened into an assault on the proposal to conduct recombinant DNA experiments at Harvard, however, and the dispute spilled over into the city when the matter was reported at length in Boston's weekly newspaper.

Approval of the laboratory by the Harvard authorities was all but assured, since the concept had been endorsed by a biohazards committee, Harvard's Committee on Research Policy, and the Dean of Arts and Sciences. But, when he read about the dispute in the newspapers, Cambridge city Mayor Alfred Velucci stepped in. He called a council meeting on June 23—ironically the day the NIH guidelines were issued—to discuss the matter, and a string of scientists testified about the potential hazards and benefits of recombinant DNA research By all accounts, the atmosphere was highly charged, and there was considerable heated discussion.

The matter has now gone well beyond the issue of whether the laboratory should be built, however, for Velucci has introduced a resolution which would prohibit all recombinant DNA experiments in Cambridge—even those deemed to have minimal risk—for two years. The council will vote on the resolution on July 7, and the outcome will be closely watched around the country. ☐

Prediction of volcanic activity and climate

from P. M Kelly and H. H. Lamb

CURRENT interest in climatic change has stemmed from the growing awareness that man's activities are everywhere circumscribed by his environment, and in particular, by the vagaries of climate. The fluctuations of weather and climate in most parts of the world have been increasingly troublesome in the past 20–25 yr. This has happened partly because of an apparently real increase in the variability from year to year, or from one group of about 5 yr to the next, which has affected the Indian monsoons and temperatures and rainfalls in middle latitudes of both hemispheres, and partly because the growth of population and the rationalisation of agriculture towards specialisation in one-crop economies in various regions has increased vulnerability to weather. Climatic change has provided a control on human affairs in certain regions in the past and now, with the ever increasing economic interdependence of nations, its effects must be considered in future planning in all spheres—industrial, social and economic. Unfortunately this need for climatic forecasts cannot yet be adequately catered for by meteorologists or climatologists, who are still trying to determine the causes of climatic change by study of the limited climatic record.

In recent years much evidence, both theoretical and observational, has been put forward suggesting that the amount of volcanic dust in the upper atmosphere may be the major control of climatic change during the postglacial. Stratospheric dust effectively reduces the amount of solar energy reaching the Earth's surface where this energy is made available to the atmospheric circulation and variations in the amount of this pollutant, caused by the varying frequency and magnitude of explosive volcanic eruptions, may produce corresponding fluctuations in the nature of the atmospheric circulation and climate. If this hypothesis is correct, prediction of climate will first necessitate prediction of volcanic activity. Although great steps are being taken in the forecasting of volcanic activity on time scales of days, prediction of volcanic activity on time scales of years and decades has been considered a remote possibility (and perhaps considered by many a distinct impossibility).

In last week's issue of *Nature*, Roosen *et al.* (**261**, 680; 1976) attempted to determine one cause of fluctuations in volcanic activity on time scales of centuries and provided a possible tool for the forecasting of tectonic activity and climate. They postulate that changes in the degree of tectonic activity may arise from variations in the rate of change of lunar tidal stress effects on the Earth's core and crust. Calculation of the long term variation of the tidal stress reveals a cycle of about 179 yr due to resonance effects arising from shorter period variations in the lunar orbit. There are many references to a cycle of about this length in the literature concerning climatic change, although in most cases the length of record analysed has been too short to evaluate the statistical significance and precise period of this fluctuation; its existence is not well-established Spectral analysis of the Camp Century, Greenland ice core δO^{18} record reveals a cycle of about 180 yr and Roosen *et al.* claim that 13% of the variance of the δO^{18} record can be explained by the derivative of the tidal stress curve during the period AD1200 to AD1970. The correlation breaks down during the periods AD1420 to AD1530 and AD1650 to AD1700, an effect which the authors tentatively attribute to dominance of the effect of the exceptionally low degree of solar disturbance during those spans of years.

Roosen *et al.* note that a cycle of about 180 yr has been observed in variations in solar activity, thereby providing an alternative explanation for this variation in climate. Therefore, before the climatic cycle of 180 yr can be used for forecasting purposes, it is essential that its existence be confirmed by analysis of other long climatic records and that its cause, solar and/or tectonic, be defined.

Research related to the past record of climate and the apparent causes, and rapidity, of climatic fluctuations and changes is being undertaken by scientists in many fields other than climatology. This is providing a great stimulus with many opportunities of increasing knowledge and verifying diagnoses as new data and new techniques of measurement and analysis are put forward. It is important that collaboration between workers in all the fields involved in the study of climatic change be initiated and fostered. A multidisciplinary approach is needed, both to compile the evidence of the facts of the past climatic record and to solve the problems of the causes of climatic change, which seem to extend from the Earth's core to the Sun (and, on the longest time scales, to the Galaxy beyond). Only from the work of organisations, ranging from the powerfully equipped mathematical laboratories of the atmospheric, oceanographic and Earth sciences to academic institutes and meetings where diverse specialists can be brought together, will the knowledge and understanding needed to develop sound advice on probable future climatic development be attained The specialists will include agriculturists and forestry research workers, palaeobotanists, geologists and, in some cases, archaeologists and interpreters of ancient texts and inscriptions. ☐

Activation analysis *in vivo*

from Keith Boddy

The Second East Kilbride Conference on Progress and Problems of *In vivo* Activation Analysis, organised by the Scottish Universities Research and Reactor Centre, was held on April 6–9, 1976.

DELIBERATE induction of radioactivity in animal tissues was reported in *Nature* almost 27 yr ago and some 12 yr have passed since the feasibility of *in vivo* neutron activation analysis in man was demonstrated. The technique involves exposure of the total body or the relevant region of the body, such as the thyroid, liver, spine or limb, to a low dose of neutrons and measurement of either the induced radioactivity or the prompt gamma rays emitted during irradiation. Total body *in vivo* neutron activation analysis (TBIVNAA) is a unique method providing direct and simultaneous measurements of the total body content of calcium, phosphorus, nitrogen, sodium and chlorine. Similarly, there are partial body methods (PBIVNAA) for determining the total thyroid content of iodine, calcium and phosphorus in sections of bone or cadmium and copper in the liver. The reproducibility of measurements is generally 2–4%, permitting the detection of relatively small changes in body composition due to disease or treatment, the patient being examined on an outpatient basis.

It was clear from the increasing number of centres using, or proposing to use, *in vivo* activation analysis and from the wide range of clinical applications described at the conference that the potential of the technique in medicine is being realised. Several groups are using TBIVNAA in examinations of osteoporosis, osteomalacia, renal failure, hyperparathyroidism and endocrine dysfunctions. Regional measurements of calcium in bone are being made in some of these disorders and of thyroid iodine in hyperthyroidism

The facilities at Brookhaven National Laboratory, New York, comprising 14 sources each of 50 Ci Pu–Be distributed along the anterior and posterior body surfaces for irradiation and the sophisticated whole-body counter using 54 sodium iodide detectors, were described by S. H. Cohn A wide variety of clinical studies are in progress: in thalassaemia, for example, gross depletion of skeletal calcium (50%) has been measured.

J. H. Fremlin (University of Birmingham) and his colleagues use a cyclotron for clinical measurements involving delayed gamma-ray emission and also for prompt gamma-ray analysis of total body nitrogen using hydrogen as an internal standard, as well as for the detection of cadium in liver. In regional analyses, spinal calcium is measured. The feasibility of determining copper and ion in liver in pathological situations has been demonstrated using PBIVNAA, and preliminary studies of their measurement by nuclear resonance fluorescence were described.

W. B. Nelp (University of Washington) and H. E. Palmer (Battelle Northwest Laboratories, Washington) and coworkers also use a cyclotron in a wide range of clinical studies. The technique of measuring total body calcium using the reaction ^{40}Ca (n,α) ^{37}Ar, first demonstrated by Palmer, in which the exhaled gas is collected, purified and counted in proportional counters, is now in clinical use. To measure calcium alone, smaller radiation doses can be used and whole-body counting is not required. This technique has also been adopted at Birmingham and at the Memorial Sloan Kettering Cancer Center, New York (J. S. Laughlin). The rate and completeness of exhalation of ^{37}Ar has been examined in detail by several groups. Although the exhalation pattern found was obviously complex, there was preliminary evidence that the technique was reproducible and could estimate total body calcium quantitatively in man.

The Medical Research Council cyclotron at Hammersmith Hospital is used by T. Spinks and colleagues for similar studies, and in some cases they measure calcium in the hand and the rate of removal of induced ^{24}Na.

In the system used at the University of Toronto by K. G. McNeil and J. E. Harrison, 12 sources each of 5 Ci of Pu–Be are distributed only about the thorax and lumbar region of the patient, precluding absolute measurements of total body content. But calcium and sodium indices have been derived, relating the expected counting-rates of these elements to body habitus, and the measured counting rate in the patient is compared with that expected as an indicator of normality. This approach has been used in various clinical disorders. Measurement of nitrogen *in vivo* is also being attempted by the prompt gamma-ray method.

At East Kilbride, K Boddy's group uses scanning irradiation with two sealed-tube 14-MeV neutron generators and a scanning shadow-shield whole-body counter for TBIVNAA. Changes of body composition in rheumatoid arthritis during treatment with non-steroid analgesics and with corticosteroids have been studied. The nuclear reactor is used to measure the thyroidal content of iodine in hyperthyroid patients, as M. J. Hooper (Western Infirmary, Glasgow) reported. A technique of "compound irradiation" with mixed neutron beams has been developed to improve the uniformity of activation in partial body calcium measurements.

A facility using two californium-252 neutron sources each of 200 μg for partial body *in vivo* neutron activation analysis, developed by the East Kilbride group, is being used for clinical studies by M. A. Smith and colleagues at the Western General Hospital, Edinburgh. A much larger californium-252 source of 3 mg is used by A. D. LeBlanc and colleagues at Baylor College and the NASA/Johnson Space Centre, Houston, in a facility for measuring regional changes in skeletal calcium in man and whole-body measurements of small animals. A facility described by B. Mazière (CEA, Orsay), uses two sources each of 200 μg of ^{252}Cf together with four sources each of 10 Ci of ^{238}Pu–Be for the simultaneous measurement of calcium and phosphorus in the hand.

Many participants felt it was desirable to be able to compare directly the results from different centres. A proposal by Palmer to establish an international intercomparison, based on anthropomorphic phantoms containing human skeletons, to be measured "blind" by the various groups and subsequently analysed chemically, was received enthusiastically. Palmer and Boddy were appointed co-chairmen with the task of establishing the interlaboratory comparison. ☐

Influence of grazing

from Peter D Moore

SOME controversy surrounds the degree of influence exerted by man's grazing animals on the vegetation of the arid parts of the world. There is much room for argument and speculation simply because there is a paucity of factual information, particularly regarding the history of vegetation development. The processes at work have taken considerable periods of time—many millennia in the case of the Middle East—and the separation of climatic and anthropogenic influences often proves impossible in attempts to assess the underlying factors which have determined the structure and composition of extant vegetation Some effort has recently been made to approach the problem from the point of view of excluding grazing animals and observing the development of plant communities within exclosures. But at best, such experiments will take many decades before any important conclusions can be drawn, and it is possible that some species will no longer be in a position to reinvade such experimental plots.

The problems faced in such places as North America and Australia are rather different from those of the Old World in that the history of man's pastoral activity is much shorter and is generally well documented. In such conditions there is a better chance of elucidating any changes in vegetation which have occurred during this time One approach which has recently been used is the analysis of population age structure in selected arid shrubs. If grazing pressures have severely influenced seedling survival, it should be possible to demonstrate that the younger shrubs are present at lower densities than would be expected for the maintenance of overall population levels. Crisp and Lange (*Oikos* **27**, 86; 1976) describe just such a study which they have undertaken on the shrub *Acacia burkittii* at Koonamore Station, a sheep-grazing area of southern Australia

Sheep grazing began at Koonamore in the 1860s at a density of 0.4 sheep ha^{-1}, and it is recorded that within 50 yr the vegetation had become badly degraded. In 1925 an area of this range (400 ha) was fenced to exclude rabbit and sheep grazing and studies of consequent vegetation change have been carried out. Some permanent plots were marked out and within these the *Acacia burkittii* has become established. As a result precise ages are known for several of these shrubs. On the basis of this knowledge, Crisp and Lange have produced a linear regression of a bush size index (height plus diameter) against age. Even in the absence of annual growth rings this permits the estimation of shrub age on the evidence of its size, though data are available only for shrubs less than 42 yr old. Similar calculations were made for a stem girth/age relationship and it was assumed that a linear extrapolation could be made from this to estimate the ages of the older shrubs (maximum calculated age was about 250 yr).

These figures can be used for the examination of the age structure of *Acacia* populations, and this has been done both in regions with almost a century of sheep grazing in their history and also in those which have experienced no sheep grazing, but only that of rabbits. Population histograms from all sites examined show high frequencies of shrubs of a century in age, but lower frequencies of younger shrubs. In a stable situation we would expect younger individuals to be at least as frequent as older ones up to the development of senescence. Reduced frequency of juveniles can often be correlated with the commencement of sheep grazing in the latter part of the nineteenth century, though rabbit grazing presents a complicating factor. In one site where there has been no sheep grazing, but only rabbit grazing, there is still a reduced frequency of shrubs in the 25–50 yr age group. Where grazing has been maintained to the present, the occurrence of *Acacia* shrubs less than 50 yr old is very low, or such juveniles are absent. Where sheep grazing was curtailed in 1925, there is a high frequency of young individuals, in spite of continued rabbit grazing.

There are several possible explanations for the form of these histograms apart from the sheep grazing effect. It is possible that a change in a climatic factor about 100 yr ago reduced the survival potential of *Acacia burkittii.* Crisp and Lange claim that reproduction in this shrub is not significantly affected by rainfall, but it is possible that the population of a natural predator of the seeds or seedlings, vertebrate or invertebrate, may be so influenced. There is also a possibility that *Acacia burkittii* is not a climax adapted species, but occupies a temporal niche in a successional development. There are many instances on record of species which invade and may even dominate a habitat for several decades during the course of succession but which fail to maintain viable populations in competitive conditions. For example, birch (*Betula pendula*) in temperate European forests invades areas after catastrophes and produces even aged populations. Twenty or 30 yr after invasion, the age structure of the population would look very similar in its basic shape to that of *Acacia,* for seedling establishment under a birch canopy is very poor in this species. Some successional dominants, such as *Typha latifolia* (McNaughton, *Ecology,* **49,** 367; 1968) secrete compounds which directly inhibit seedling germination which has the advantage of reducing self-competition.

Such alternative explanations, however, do not explain how the removal of sheep grazing can so profoundly increase the recruitment of new seedlings into the *Acacia* populations By far the simplest explanation is the one propounded by Crisp and Lange, that the introduction of sheep grazing in addition to natural predation and increasing rabbit predation, has placed an unacceptable demand on the regeneration potential of *Acacia burkittii.* The forecast from this data is that as time proceeds and older shrubs senesce and die, there will be little or no replacement and *Acacia* will become scarce. The implications of this for the general ecology, hydrology and pedology of these areas are of course unknown. ☐

Purine and pyrimidine metabolism

from A. C. Allison

A symposium on Purine and Pyrimidine Metabolism was held at the Ciba Foundation on June 9–11. The proceedings will be published early in 1977 by Elsevier/Excerpta Medica/North Holland.

So far most effort has gone into mapping metabolic pathways and their genetic control, and detailed information about purine synthesis in bacteria and fungi is now available. Much less is known about control in mammalian cells, but inherited deficiencies of enzymes of purine metabolism continue to yield interesting information. It has been known for some years that deficiency of hypoxaxthine-guanine phosphoribosyl transferase leads to excessive uric acid excretion and abnormal function of the central nervous system, including compulsive self-mutilation. This enzyme catalyses one of the salvage pathways of purine synthesis: the other depends on adenine phosphoribosyltransferase, and the clinical manifestations of deficiency of this enzyme in three patients, belonging to two families, were described by A. Simmonds (Guy's Hospital, London), working in collaboration with K. J. van Acker (Antwerp) and P. Cartier (Paris). In these patients adenine cannot be reutilised and is metabolised to 2,8-dihydroxyadenine which, being very insoluble, crystallises in the urine. The resulting stones can be confused with uric acid stones. The children have no neurological defect and respond well to allopurinol treatment.

Other inherited defects of purine metabolism are associated with immunodeficiency Purine nucleoside phosphorylase deficiency affects mainly thymus-dependent lymphocytes, whereas adenosine deaminase deficiency affects bone marrow-derived lymphocytes as well. W. N. Kelley (University of Michigan, Ann Arbor) reported that adenosine deaminase is present in a highly active small form (molecular weight 36,000), an intermediate form (114,000) and a large form (298,000). In human lymphocytes stimulated by mitogens T. Hovi (University of Helsinki) has found an early and sustained increase in *de novo* purine synthesis, and immunosuppressive drugs such as azathioprine and methotrexate inhibit this pathway.

These and other observations raise the possibility that purines can control not only purine synthesis (already well established) but also pyrimidine synthesis and even nucleic acid and protein synthesis. For example, when purine nucleotide levels in mammalian cells fall, nucleolar polymerase A activity declines and precursor ribosomal RNA is no longer synthesised. ADP-ribosylation of proteins may represent a major controlling system.

Another new idea that was discussed was the role of purines, especially ATP and adenosine, as neurotransmitters. This was enthusiastically expounded by G Burnstock (University College, London) and could have important implications in neurological diseases related to purine metabolism. ☐

Magnetic dating

from a Correspondent

For more than two decades, palaeomagnetists have been studying the magnetisation of rocks in order to construct polar wandering curves and to define the nature of recent secular variations of the geomagnetic field. Although this work is far from complete, the interest within the subject is turning increasingly towards using such observations in reverse, that is to use the magnetic properties of sediments, archaeological artefacts and so forth, as means of dating the different processes which have affected these materials by comparison with the increasingly well established magnetic chronology. This changing emphasis has been indicated by two recent meetings in the Department of Geophysics and Planetary Physics at the University of Newcastle upon Tyne. One was concerned with the possible application of palaeomagnetic techniques to sedimentological problems (held on May 14) and the other (held on January 8–9) with the status and development of the application of the same techniques within archaeology.

The meeting of geological interest was concerned chiefly with the formation of haematite within sandstones. It is well known that it takes some 5 to 10 Myr for rock debris in modern desert environments to change in colour to the reds associated with ancient desert sediments. B. Waugh (University of Hull) reported evidence on the different reactions involved in this breakdown, which has obvious implications for the time at which the haematite is formed and therefore the actual date of the magnetisation compared with the rock itself. Many red sediments seem to carry a magnetisation which is unrelated to this coloration as the pigment is too fine grained, but D W. Collinson (University of Newcastle upon Tyne) presented convincing evidence that in some red beds, the stable magnetisation is associated with the red pigment rather than detrital particles. Studies of Devonian sediments from Scotland, described by F. Turner (University of Aston) and R. Archer (University of Newcastle upon Tyne) showed that haematite formation in such desert sediments can be delayed for as much as 100 Myr, the diagenetic changes presumably being inhibited by a high initial organic content. If this is so, then magnetic dating of the formation of the haematite may also provide the age at which the release of liquid hydrocarbons from these lacustrine sediments finally ceased.

M. Noel (University of Newcastle upon Tyne) discussed the way in which the magnetic remanence and fabric change during deposition, thus leading to an improved understanding of the sedimentological processes and determining the original fabric of a rock before it is compacted and subjected to tectonic stresses. There was also some discussion of the way in which palaeomagnetic techniques could assist in the dating of dolomite formation (M. Tamar-Agha, University of Newcastle upon Tyne) and the identification of past environments, such as the determination of current flow when more standard markers are absent

The archaeological meeting was initially concerned with instrumental developments, reported by participants from the University of Newcastle upon Tyne, that now make possible much faster measurement of the remanence (L. Molyneux) and other magnetic properties of materials (A. de Sa), but also mean that a wide range of materials (D. H. Tarling) previously regarded as virtually non-magnetic, can be examined for their potential use in archaeomagnetic studies. Results from Bulgaria (M. Kovacheva) and Japan (K. Hirooka) were particularly interesting as they seem to indicate a synchroneity of behaviour in both areas. If this is confirmed, it suggests that a significant part of the secular variation of the geomagnetic field is attributable to 500 and 1,500-year wobbles of the main dipole. R. Thompson and N. Abrahamsen (Universities of Edinburgh and Aarhus, respectively) described studies of sediments, particularly in present-day lakes, which suggest that other components of secular variations are very localised and not attributable to the westward drift of the non-dipole field.

The meeting, however, was not so concerned with the implications of these studies for the origin of the Earth's magnetic field, but mainly with the ways in which sediments, although not ideal recorders, can be used to monitor geomagnetic changes and thus can be used for archaeomagnetic dating. One surprising feature was that sand-sized sediments seem to be better recorders than fine clays over achaeological time, as A J. Clark (Ancient Monuments Laboratory) reported, although the opposite seems to be true of geological deposits. There was discussion of the implications of geomagnetic changes on the climate (N.-A. Mörner, University of Stockholm) and production of ^{14}C (J Klein and H. Tauber, Universities of Pennsylvania and Copenhagen, respectively). Some correlations seem to exist, but it is difficult to determine how these processes interact with each other. Changes in the total magnetic moment of the Earth should only have minor affects on the ^{14}C inventory and it seems possible that any climatic response to changes in the height of the ionosphere may be the main agent in varying the interchange of carbon between its different reservoirs.

Both meetings tended to concentrate on the significance of the increased use of sediments in palaeomagnetic studies. There are obviously major problems in understanding the complex processes involved during deposition and it will be increasingly possible to study such behaviours magnetically, but it is also obvious that extreme care has to be taken in the use of sedimentary magnetisation for precise determination of previous geomagnetic properties. ☐

A hundred years ago

We publish below a correspondence which we cannot but regard with the greatest satisfaction; Government has at last seen it to be its duty to act upon the recommendation of the Duke of Devonshire's Commission, and make a substantial contribution towards the endowment of pure scientific research. We need scarcely remind our readers that from the first we have maintained that such endowment is the duty and interest of civilised states.

from *Nature*, 14, 185, June 29, 1876

200 years of American science

Reflections on 200 years of science in the United States

Nathan Reingold

Smithsonian Institution, Washington, DC 20560

In spite of its obvious importance today, the history of the sciences in the USA is usually neither the subject for research nor part of courses taught by non-American historians. Nor is this history known and understood, particularly in Europe. This is in marked contrast to an avid interest in current US science policies and developments, which cannot be wholly explicable without an understanding of their historic origins. Broadly speaking, these origins are US variants of certain western European traditions resulting, as it were, in cults of knowledge, nation, and people. Science and scientists have flourished, but uneasily, in the resulting environment.

EARLIER this year a British historian of science wrote to me to say he was giving a few lectures on the institutional history of American science before 1914 in his course. I was astonished. Hardly any non-American historians do research or display interest in science in the USA; presumably their courses reflect this. An East German has a few pieces dealing with astronomy; a Dutch historian this year published an article on a nineteenth century American physicist; a few years ago, British geologists did a multi-volume history of geomorphology, a field they defined as overwhelmingly derived from US geologists.

In contrast, there is no shortage of writings and courses outside the USA on science policy or sociology of science with strong emphasis on recent events in America. Nobel Prizes are counted, statistics marshalled, and very current trends analysed. In this dispensation, science in the USA starts with a contemporary occurrence—the Mansfield Amendment, Sputnik overhead, the atom bomb, or the arrival of refugees from Hitlerism. But research and development in the USA is important on a global scale. It did not spring up overnight but was the result of a complex, fascinating historical metamorphosis. In 1776 the British North Americans, south of former French Canada, had one great investigator, Benjamin Franklin, and a handful of others we can denote as scientists. By 1900 the new nation had essentially evolved a vigorous scientific community with many of the basic structural and functional characteristics so evident today. This included strong commitments to fundamental research in various fields. In the present century these characteristics produced what is now so visible. It is a meaningful historical movement, not simply a banal success story, and deserves critical scrutiny by scholars. Rather than give a recital of great names and notable contributions, or genealogies of institutions, let us consider the sciences in America as a set of historiographic problems particularly worth studying in comparative prospect.

Influence of De Tocqueville

Americans and Europeans are still influenced by De Tocqueville's *Democracy in America* (1835). The work is best described as a hortatory essay to the French in the form of an account of a mythical country perversely given the name of a real republic on the continent of North America. Noting the absence of the usual landmarks of European history—kings, churches, nobles, castles, dynastic squabbles and sectarian wars—De Tocqueville concluded that the mechanism of American history was different, a vast arena for the smooth workings of impersonal dynamic laws. He approved this lack of romance, drama, and great trends because of the desire to avoid the disruption of revolutions. This view recurs in the influential writings of Henry Adams, the descendant of Presidents who cast a jaundiced eye both on his society and on the consequences of science. That he thought America and China were alike in this sense says much about his insight into both histories. Like the immigrant myth of gold in American streets to explain prosperity, this Newtonian line of reasoning aborted analysis; change simply occurred, obviating any need for study of the prior actions of men and institutions.

De Tocqueville noted the presence of energetic go-getters intent on acquiring wealth, and he met no savants, devotees of abstract thought who required a niche immune from daily pressures in a hierarchical aristocratic society. A democratic society was technologically oriented and indifferent to basic research. In fact there were scientists in *ante-bellum* America. Someone like Nathaniel Bowditch, the translator of Laplace, or Joseph Henry at Princeton, might have dented his certitude. Or going forward in time to a school chum of Henry Adams, the mathematical physicist turned idealist philosopher, Charles Sanders Peirce, was every bit a grand savant. And there were others.

De Tocqueville did not say there would be no science nor great pure scientists in the United States. Applied science would yield bits of basic science—that is, he was of an older view that did not see basic science as logically and chronologically anterior to technology. And by chance a great pure scientist might arise in the American republic. De Tocqueville believed that pure science ideally required the individualism, the drama of an aristrocratic order. Although he was wrong in predicting a steady-state country (and Henry Adams in seeing the heat death of entropy), De Tocqueville had grasped an important truth. The western European ideal of a value-free science independent of society would take different forms in the USA. One can argue the extent to which this ideal was realised in Europe; the structured society of its nations, at the very least, permitted the illusion of realisation. Great men, ideas, great events existed, at least figuratively, in isolation. In the USA, their analogues were often bathed, if not immersed, in social, political, economic, and ideological realities.

To this day, many American scientists incline to the view that their society is indifferent, if not hostile, to basic science, in spite of ample evidence of the growth over time of support for research, even of the most abstruse nature. A proper perspective on this peculiar attitude is a comparison with literature, music and art. Once they too were presumed blighted by the American environment. A democratic society could support popular or vernacular cultures but not high cultures. No one makes this accusation any more in art, literature, or music. They flourish in symbiosis with the popular culture. Only in science is there uneasiness and sensitivity, obviously a phenomenon of great importance.

'Old West' influence

Early in the 1850s the aged Alexander von Humboldt wrote approvingly of American efforts in a wide range of physical and biological topics related to geography. Because he wanted Americans to receive greater international visibility, Joseph Henry of the Smithsonian Institution suggested preparing what eventually became the Royal Society's catalogue of scientific literature of the last century. As Henry originally limited the work to the exact sciences, he clearly had more than scientific geography in mind. Although the first series of the catalogue to 1863 disclosed that roughly 5% of the authors were from the USA, Europeans were not impressed. By the end of the century American activity in the earth sciences loomed large. Although an extension of Humboldt's view, geology reeked of the romance of the Old West, so attractive to generations of man-boys on both sides of the Atlantic. It did not hurt that the leader of the geological community in American was John Wesley Powell, whose hand was lost at Shiloh in the Civil War and who had first explored the untamed Colorado. Powell's other role as a pioneer ethnologist only heightened the effect. Although very creditable, the scientific exploration of the West was like the rumoured gold in the streets, something waiting there. It did not impress those interested in mathematical and experimental fields. But only by 1951–52, did a French geologist, Emanuel de Margerie, produce his two volume *Etudes américaines*. A few works noted that astronomy had become a very active discipline in the USA by 1900.

Shortly after that date, a significant act of recognition occurred. Reacting to the founding of the Carnegie Institution of Washington and the Rockefeller Institute, the Germans founded the Kaiser Wilhelm Gesellschaft. In the years before the First World War, a number of German observers commented favourably on the quality and scale of the sciences in the USA, warning against the threat to German hegemony in research. Apparently, the familiar competition of Britiain and France was less worrisome. One of the Carnegie beneficiaries, the astrophysicist George Ellery Hale, added Rockefeller funds and built the great 200-inch telescope at Mount Palomar. That great instrument and E. O. Lawrence's pre-Second World War cyclotron symbolised science in the USA to many on both sides of the Atlantic. Large scale reflected the natural endowment; great instrumentation reflected the supposed American propensity for 'practical' devices, not for the abstruse theorising of true savants. Attributes of Hale and Lawrence reinforced these stereotypes. Hale was a fabulous promoter and organiser, a veritable Morgan or Rockefeller of science; Lawrence, also a manipulator, went on to invent a television system. Usually overlooked were scientists of a different mould. A contemporary of Hale's, the great geneticist Thomas Hunt Morgan used the fruit fly in a series of austere, rigorous experiments. With a passion for scientific exactitude, he shunned empire building and applications. When Hale and Robert A. Millikan invited Morgan to the California Institute of Technology, they initially envisaged a programme of science applied to medicine; Morgan insisted on pure research. Although the USA was a world power in the sciences when Morgan went to Pasadena, a generation passed before a sustained serious historical research began and then largely because of the events of the Second World War and their consequences.

The emergence of American science

This 200 years of history is not explicable by any assumptions of American singularity. Like the nation, the sciences in the USA are part of western civilisation. The thirteen rebellious colonies were a provincial outpost of this civilisation. It is not wholly accidential that the first college in this country was founded in 1636 in Massachusetts Bay Colony in a village named Cambridge. Modern science originated in western Europe and developed an eastern wing in Russia and a western one in the USA. In spite of the obvious influence of British (and French) science, the most interesting comparisons and relations of the research scene in these former colonies of the UK are with Germany and the Soviet Union, a point to which I will return.

Because of its origins as a provincial outpost of western Europe, the USA was never properly described as a young country, that is, a country lacking the kind of history associated with the cultures of the European nations. More precisely, the USA had never experienced a youth consisting of dynastic and sectarian violence, a rigid class structure, and an all-powerful established church. It was born to adulthood in the sense of having many of the trappings of modernity. To conservatives, the lack of the usual traditions and their detritus was a basic flaw; to liberals and radicals their absence was a glorious opportunity. With some exceptions, both were sceptical about developing a high culture of science in a democratic environment.

In 1776, the USA was not a blank slate. Selectively, patterns of life and thought of seventeenth- and eighteenth-century

Europe flourished and persisted; in time they became Americanised, diverging from a western Europe undergoing its own reactions to intellectual and economic changes. At the same time, a kind of feedback from these European developments prevented any gross cultural split between the populations on both sides of the Atlantic. In the USA there was an avid pursuit of the European printed word. Even modest cities of the Mississippi valley in the *ante-bellum* era possessed a good number of books and journals. Young scientists visited Europe, and many went on to study at overseas universities. A Louis Agassiz came in 1846, as did many others in the last century. The German emigrés of the 1930s were simply an instance in a two-century-old process. In 1973 about 6,000 scientists and engineers emigrated to the USA. At all times in its history a minority of the scientists were foreign born.

Scientific heritage

The colonists in revolt insisted they were only asking for their just rights as Britons, even though most in the UK probably did not see the rights in that way. Facing western Europe, American investigators regarded science as part of their heritage; ruthlessly and cynically they brought over the ocean whatever they wanted of this scientific heritage, disregarding any plaints about the European nature of the best of science. Being provincials in the eyes of western Europe, they were often infuriated by patronising treatment. In fact, American scientists were still vexed by patronising Europeans as late as the years between the two world wars. Yet, from the very beginning, American investigators wanted nothing as much as the good opinions of their peers in Europe; at the same time many strongly desired to present their results as a symbolic return to Europe for the great gift of science.

Because of this ambiguous relationship with European science, the American scientific community developed a differing pattern of nationalism and internationalism than their overseas counterparts. Let us disregard the fatuous cliché that "The sciences were never at war". It is a meaningless truism applicable to sets of concepts and data, not communities of humans. Real, live scientists usually rise and salute when the flag is raised, especially during wartime. Even in peace, national differences and rivalries influence the behaviour of scientists. Being outside the rivalry between the French and Germans after Sedan and not sharing the British anguish that Perkin discovered the dye but Germany garnered the industry, American scientists could work very comfortably in an international setting. At the same time, national interests were never totally absent.

Another differing pattern arising from colonial roots is the development of a cult of the people, substituting for king, nobility and gentry. In a post-First World War movie about a hack senator trying for the presidency, William Powell in the title role makes a campaign promise to give a Harvard degree to every American at birth. Mass culture, like dreams, sometimes disclose suppressed beliefs. Just as scientists (and conservative critics) were uneasy about the lack of a proper hierarchy and widely agreed on norms, the American public had qualms about status based on education. Contrary to popular belief, the nation inherited a class system from Europe and still displays a social stratification based on wealth. Contrary to De Tocqueville, quite a number of families retained high status over many generations, in some instances even constituting a patriciate. This is in spite of a significant degree of upward mobility in the past for all groups with the notable exception of those of African descent. Yet classlessness is widely assumed in the form of crowding to a middle position.

Education

Education can provide a status countering classlessness. Traditionally, expertise is highly valued here. At the same time, it is one of the glories of American history that the learned have much power and honour but lack the certainty of an assured niche. When historians turned to the history of the sciences in America, they noted that scientists wanted an elite, meritocratic basis for their group, often rejecting the validity of public intrusion into their affairs. Filled with such historiographic problems, I spent a year in Britain in 1964–65 studying British analogues of my favourite nineteenth-century American scientists. An acquaintance in the Civil Service, now deceased, invited me to lunch at the Athenaeum Club. As I looked around, he said, "This is like your Cosmos Club in Washington". But I knew differently. Just a few days before I had read in manuscript a letter from an officer of the Royal Society to a council member, then little known. Charles Darwin was invited to the Athenaeum for lunch to discuss a matter before the Society. From my readings of many manuscripts, I had already concluded that in comparison to these British scientists, my American 'elitists' were raving egalitarians. Even if they had not been infected with republican or democratic principles, a continuing establishment control was not feasible given the size and complexity of the USA.

Smithsonian Institution

Charles Sanders Peirce (1839–1914).

Just as wealth conferred status over generations, so did education and intellectual attainments. Family groupings of scientists appeared in the last century. For example, modern geodesy was brought to the USA by the Swiss–American Ferdinand Rudolph Hassler. A generation later the Nova Scotia born mathematical astronomer Simon Newcomb married a Hassler. Their daughter became the wife of W. J. McGee, the geologist and anthropologist who was one of John Wesley Powell's lieutenants. Charles Sanders Peirce's father and brother were professors of mathematics at Harvard. J. Willard Gibbs' father (of the same name) was a professor of languages at Yale. William James' father was a Swedenborgian philosopher, undoubtedly a surprise to his teacher, the physicist Joseph Henry. A present foreign Fellow of the Royal Society is a third generation scientist.

These family groupings have never constituted an intellectual aristocracy because of the rapid growth of the scientific community over the past two centuries. A founder of the Institute for Advanced Study, the mathematician Oswald Veblen's father studied physics at John Hopkins during its golden age; he later taught at a midwestern university. Oswald's uncle Thorstein became a great social theorist. They were a family of Norwegian immigrant intellectuals. A small town in South Dakota produced two notable physicists, E. O. Lawrence and Merle Tuve. The so-called new immigration from eastern and southern Europe by now has yielded scientists of Jewish, Italian, Slavic and other ancestries. In spite of the persistence and importance of a few families as sources for recruits, the scientific community has never been a closed group. The newest immigrants from Asia are entering the various disciplines. By now about 5% of science and engineering doctorates are of Asiatic origin. Fifteen years of consciousness raising may very well result in an inflow of Blacks, women, Chicanos—even some more American Indians.

In the USA, scientists are overwhelmingly a middle class group. In spite of individuals from the upper class and some from the lower, becoming a scientist until recently was a means of going from the lower to the upper middle class. At present such social mobility seems on the wane. If true, it is all the more important to study that portion of the middle class producing the bulk of the professional classes which provides an essential element of stability in the USA. Relatively little is known about such families in contrast to concern for the genteel culture of the patriciate or the pains and traumas of the poor and the outcast. As scientists are less numerous, they are more accessible to research than other professional groups. Where family influences are lacking, we still do not know why a small minority of middle class youngsters in the past opted for scientific careers, until very recently a choice of limited remuneration and power.

Perhaps the youngsters acted because they, like most Americans, adhered to a cult of knowledge. Here the comparisons between the USA, Germany, and the Soviet Union are important. For more than half of its history, the USA was unknowingly in a race with Germany. Early in the eighteenth century, nearly 150 years before the UK, the Prussian state made elementary schooling compulsory and universal for males. With the later expansion of German universities, the British were fated to be overtaken. The Germans trained large numbers for particular niches in their society, each niche with a specific place in an elaborate hierarchy. The professoriate were an elite of elites, having gone beyond the doctorate in their habilitation, a point the Americans did not quite grasp when graduate schools arose under the influence of German higher education. What American scientists did note was the high status of the German professoriate. In Prussia each chair holder was a higher civil servant. American scientists often hungered for the same kind of assured high place in their own nation.

Throughout the nineteenth century Americans expanded all levels of their education system; in retrospect, they were trying to match Germany. The statistics are not very clear but, apparently, around 1900, the time Germans became conscious of an American threat, the USA had surpassed Germany in numbers, at least. Quality was another question. American universities were largely viewed as an extension of the democratic thrust to provide a responsible electorate. Some institutions viewed themselves in a patrician sense, as training cultured gentlemen for service to the society. Typically, even the mass schools regarded themselves as engaged in both cultural uplift and in a service role. The sciences served both purposes. Mass plus quality tended to become the ideal.

A number of examples. In the middle of the large state University of Illinois at Urbana before a library with nearly four million books is a plot of corn planted to remind all of the university's origin as a land grant school for agriculture and mechanic arts. When the University of Chicago opened its doors in 1891, it was a great university. This oft repeated judgment refers to its scholarly research strength. But its President, W. R. Harper, at the same time launched an extension programme of correspondence and evening courses. The Professor of Mathematics at Chicago, Eliakim H. Moore, the first pure mathematician elected to the National Academy of Sciences, received an honorary doctorate from Göttingen early in this century. He conceived his authority to extend from research in pure mathematics to supervising the training of elementary school teachers of arithmetic. Moore, Chicago, Illinois—like many other American institutions and individuals —wanted theory and practice, culture and service, elite and mass somehow combined or in juxtaposition.

The Soviet Union and the USA are probably the only remaining countries still believing in some form of the idea of progress, a Marxist version in one, and Enlightenment variant in the other. The two countries have curiously parallel histories in the sciences. Both were Humboldtian because of the need to manage their large land masses. Both turned engineering into mass professions of high status. The Russians have won the numbers race in that category, a more serious fact than mere heft of armed might. The USA lagged behind Russia in pure mathematics, and may still. Russian universities have a much different role in the sciences. Centralisation is greater in the Soviet Union, whereas egalitarian instincts limit centralisation in the USA. Our society has a primal urge to replicate anything deemed desirable. In addition, strong anachronistic sentiment for rusticity ultimately works against the big. Rusticity is something the Russians shun.

Besides the idea of progress, the cult of knowledge in the USA has other traces of the seventeenth and eighteenth centuries now largely absent from western Europe. By establishing much of the broad form and content of what now designated science, the Scientific Revolution defined some concerns as non-knowledge and started segregating the high culture of the sciences from the vernacular culture. But the useful arts partially escaped this exclusion until the nineteenth century. At the same time the casual amateur and the modest practitioner were increasingly displaced by the savant. (Significant scientific amateurism probably survived longer in the UK and the US than in Europe.) The scientific revolution gave form to a previously rather loose, amorphous conglomeration; and the Industrial Revolution hardened the new pattern.

Much of this process had by-passed the British North American colonies. The vernacular, the non-science, the amateur and the applied, survived and flourished after independence when the high culture of science began a slow steady growth. Europeans established a scheme of things in which there was a congruence between social, intellectual, and institutional hierarchies. Not a perfect congruence, but enough to avoid many of the problems of the Americans. On the western side of the Atlantic, the heritage of the past and the thrust of historical development did not neatly separate grand savant and practitioner; theoretician and earnest mechanic; the abstruse and the vernacular. They were scrambled together. A persisting tension developed between the scientific elite and their perception of fundamental research and the mass community and their thrust for diffusion of knowledge (often older and sometimes applied). As a result, the cult of knowledge in the US encompassed a research ideal, but not a basic research ideal in spite of all the exertions of many generations of scientists.

In this research ideal was a blurred boundary between theory and practice. Originally, religion provided a basis for pure research. The idea of design presupposing the existence of a Designer readily yielded a drive for research untrammelled by sordid motives. Secularisation purged the theological mission, leaving a pure research ideal. At the same time the old, general notion of the utility of knowledge was elevated by this association with a designing deity. All research carried out His purpose and disclosed His will. Only overly rationalistic, sensitive scientists worried about the problems of defining discrete forms of research styles and goals.

Although a happy compromise, even before the Civil War, American scientists launched a counter strategy, to fractionate off basic research by establishing enclaves largely immune to the national tendency to conflate theory and practice.

Higher education often served as the site of these enclaves. A notable recent example is the Institute for Advanced Study. As it were, the scientists were levying an overhead charge for theoretical science against the gross national product. Many were uneasy about the more common mode of supporting theoretical science, which also appeared before the Civil War. This is to define applied missions so as to necessarily include a basic research component. In the 1920s Harvard's E. H. Hall (of the Hall Effect) corresponded with C. J. Davisson (a future Nobel Laureate) of Bell Telephone Laboratories. Impressed by Davisson's work, Hall sent the head of the Laboratory, H. D. Arnold, a letter praising the company's enlightened support of basic research. Nothing of the sort was intended, Arnold replied; we are simply interested in ways of increasing the supply of electrons. Sweeping mandates like this are widely present in so-called mission-related research. Believing sincerely in their approach, the scientists still argue in favour of broad definitions of applied missions. But many also favour protected enclaves for basic research not subject to the vagaries of economics, international affairs, public health policies and the like. Yet, it is naive to hope for and expect immunity from the ebb and flow of history.

In spite of $32 billion for research and development in 1974, in spite of over a half million engaged in research and development, in spite of $4 billion for basic research, US scientists are still uneasy about their place in society. There is an overwhelming cult of the nation with dominating symbols—George Washington, the flag, the national anthem, Abraham Lincoln, the Statue of Liberty. Science is not represented among the symbols of the cult of the nation; even technology once had the iron horse and Thomas Edison. And our country has just gone through ten terrible years raising nagging doubts about progress. Largely because of the anti-science quirks of Lyndon Johnson and Richard Nixon, inflation has eroded the real strength of the national research budget.

From the vantage point of my ivory tower, I find prospects encouraging, starting with President Ford's increase in the budget to make up some of the slippage from the Johnson and Nixon years. American scientists have always functioned well while loudly complaining. Even before the Civil War, they demonstrated great talents as entrepreneurs, improvisers and artful dodgers. Nor am I nonplussed by the predicted numbers of surplus PhDs. Except for about fifteen post-Second World War years and perhaps a few years before the Great Depression, there has always been a surplus of scientists on paper. A surplus can act as a stimulus, both on the nation and on individuals.

Whatever happens, the course of the sciences in the USA will remain an arena of tensions and ambiguities, a historical movement in which prosaic reality turns out to be a symbol, often exhilarating, sometimes grotesque, occasionally a black comedy. It has been a history of trying to have one's cake and eat it. But perhaps that is true of all of the past 200 years of our national life.

I thank the US National Endowment for the Humanities for support.

The rise of 'prostituted' physics

Spencer R. Weart

Director, Center for History of Physics, American Institute of Physics, 335 East 45th Street, New York, New York 10017

"From its origins to the present day, American academic science has been permeated by the influence of American business". The reciprocal influence, of science on business and industry, has grown dramatically in the twentieth century. The rise of industrial research and its sustained vigour during this period is charted.

"WE are tired of seeing our professors degrading their chairs," physicist Henry Rowland told the American Association for the Advancement of Science in 1883, "by the pursuit of applied science instead of pure science . . . lingering by the wayside while the problem of the Universe remains unsolved"[1]*.

Like other leaders of science he was struggling to create in the universities a spirit of pure research, free from the dangerous temptations of commerce. The task proved hopeless: from its origins to the present day American academic science has been permeated by the influence of American business. The reciprocal influence of the colleges and universities on business was for a long time not as important—nor could it be, given the small size of the scientific community. For example, in 1900 there were slightly over 200 academic physicists in the USA[2]. They were already more numerous there than in any other single country, but were still too few to have much effect; the great advances academic physics made in the nineteenth century were usually put to practical use by semi-educated inventors and entrepreneurs. The number of physicists was, however, doubling every ten or twelve years. Over the next four decades academic physics, and science in general, entered into a new relationship with American industry. It was a relationship that became essential to the strength of both partners (for a general treatment and bibliography of US industrial research see ref. 3).

It was true, as Rowland complained, that during the nineteenth century some American professors were almost too familiar with the requirements of industry. Sometimes they would give free advice, as Joseph Henry and others gave Samuel F. B. Morse during his efforts to develop the telegraph. At other times they would take a fee. American colleges and universities were chronically poor, and their typical professor could neither enjoy a comfortable salary nor look forward to any pension whatsoever; nor did he have a particularly high status in his commercially-oriented society. Small wonder if he was more likely than his colleagues in Europe to pick up some income on the side. Even Rowland, when he discovered that he had diabetes and would soon be leaving his family on their own resources, took to inventing and consulting for industry. Yet the scientists remained first and last professors, working as consultants only occasionally. This was, as W. David Lewis has said, the "putting out" stage of American industrial research[4].

Around the end of the nineteenth century the universities grew greatly, becoming powerful, independent suppliers of

---

*Fuller documentation and much more detail will be found in Spencer Weart, *The Physics Business in America, 1919–1940. A Statistical Reconnaissance*," available from myself in preprint; to be published in a collection of essays on the sciences in America, edited by Nathan Reingold[10]. For unpublished sources this study has relied chiefly upon the manuscript, microfilm, and oral history archives of the Niels Bohr Library, American Institute of Physics, New York (AIP).

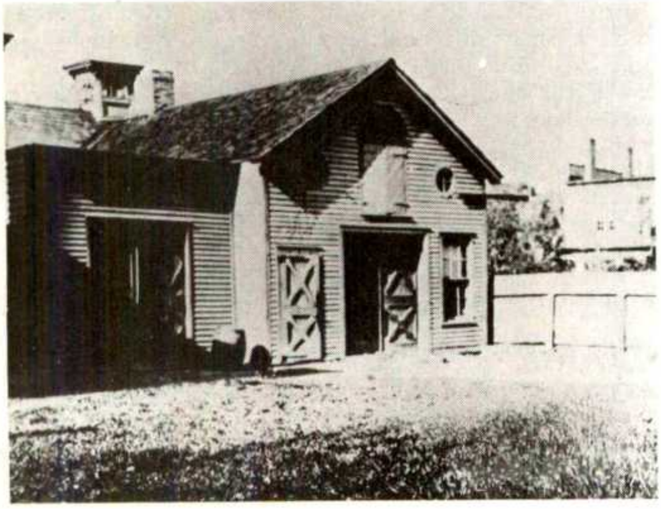
research. Industrial companies worked to encourage this development, although their contributions were small compared with the funds supplied by the governments of the various states, by tuition-paying students, and by affluent philanthropists. Nevertheless American business had a key role in this process; for example, it was from modern industrial ventures that most of the philanthropists derived their wealth.

But the universities, however strong they became, could not meet all the needs of the science-based industries which were growing rapidly around the turn of the century. C. E. Kenneth Mees, called by George Eastman to create a laboratory within the Eastman Kodak company, later explained why it was difficult for a company to have all its research done in universities. Industrial research requires persistence along particular lines of inquiry, he said, with specialised apparatus and training; this was difficult to obtain in a university and conflicted with the needs of teaching. Moreover, "the universities do not understand the requirements of the manufacturer and the manufacturer distrusts, because he does not understand, the language of the professor"[5].

The idea of solving these problems by transplanting academic scientists into business organisations seems to have originated with scientifically-trained men already working for the manufacturers. Industrial laboratories of a sort had existed for years, originally for quality control and testing, a little later for engineering and development work to improve existing products. But in 1900 General Electric established a new sort of industrial laboratory in which research was no longer tied to the day-to-day requirements of production (Fig. 1). The GE laboratories were followed within a dozen years by a number of others, notably those of Du Pont, the American Telephone and Telegraph company, and Kodak.

The professors, following Rowland's tradition, were less than enthusiastic about this development. Frank Jewett, who eventually became president of the Bell Telephone laboratories, recalled that his university mentor Albert A. Michelson "thought that when I entered industrial life . . . I was prostituting my training and my ideals"[6]. Such attitudes made it more difficult for industries to hire good staff. When GE tried to bring Willis R. Whitney from the Massachusetts Institute of Technology to head their new laboratory, they had to promise him that he could split his time between GE and MIT. After a period of commuting back and forth Whitney became so absorbed in the challenges of industrial research that he gave up his professorship[7]. This turned out to be a common experience: young scientists who moved reluctantly into industrial work soon found that it caught all their interest. Mees even warned that a lab director should take steps to keep his workers involved with the progress of pure science, lest they become too narrow[8].

Fig. 1 The first research laboratory of the General Electric company—a barn behind C. P. Steinmetz's house, about 1900.



If industrial research was clearly established in the USA in 1910, it still could not be called a major movement. But by the 1920s broad changes were becoming apparent. There was, as one physicist noted with some distaste, an enormous advance of applied physics—in industry, in government laboratories, even in the universities themselves—a "fever of commercialised science"[9]. In 1913 physicists who were located in industrial labs made up only about a tenth of the membership of the American Physical Society. In 1920 they made up a quarter of the membership and this advance took place while the total membership of the society was doubling (my calculations, taken from *Bulletin of the American Physical Society*). The proportion of papers published in the leading American journal, *Physical Review*, which originated in industrial laboratories showed a similar fundamental increase (2% in 1910, 14% in 1915 and 22% in 1920) (my calculations and ref. 10). These facts substantiate what many men were claiming at the time: the relationships between physics and industry in America were revolutionised around the time of the First World War.

The trend was already evident before America entered the war, but the war itself was widely believed to have had a central role in accelerating the transformation. Around 1917 many physicists left their campuses, but not for the Front; for them, as for most Americans, the great event of the war was a fierce intensification of industrial organisation and production. Industrialists and scientists were thrust into closer contact with one another, both at the production level and at higher levels in Washington. The result was that industrialists and physicists alike become more aware of what could be done with physics. As one industrial physicist put it after the war, "Bankers have become science-minded. They are familiar in general with the influence of scientific research on the trend of security prices." They had come to esteem science, for in "commercial warfare . . . research supplies the ammunition"[11].

Research no longer meant simply development work aimed at cutting costs and improving an existing product. In some industries it had become essential to do the sort of research, sometimes verging on basic research, which could produce an entirely new product or could keep a company supplied with information and patents for defence against new products developed elsewhere. For example, both General Electric and the American Telephone and Telegraph company were able, thanks chiefly to the trained physicists in their laboratories, to maintain a strong position when the new field of radio communication emerged around the time of the First World War. It was such large companies that had the main role in industrial research; GE and ATT alone employed some 40% of all the American Physical Society members in industry between the two World Wars (my calculations, the mean of the fractions at 5-yr intervals over the period 1920–39).

The presence of trained scientists also brought a company various indirect benefits. Publicity and prestige were perhaps chief among these. As one knowledgeable observer bluntly stated, "The use of real or imaginary research laboratories to back up merchandise . . . has an importance to company prestige that cannot be exaggerated"[12]. This was only true, of course, because the 1920s were a golden age of scientific faith, not only among scientists and industrialists but also for the public at large. The *Nation* complained in 1928 that "A sentence which begins 'Science says' will generally be found to settle any argument in a social gathering, or sell any article from toothpaste to a refrigerator" (quoted in ref. 13).

For all these reasons a good market for trained physicists developed in industry. One straw in the wind was Ernest Fox Nichols, a prominent professor of physics who had worked for the Navy during the war and who in 1920 resigned from Yale to join GE. "The position," he informed the university as he departed, "offers complete freedom in the choice of research problems, and places at my unhampered disposal such human and material resources as no university I know of can at present offer"[14]. He might have added that industrial salaries left the universities far behind. Fears were expressed that the ranks of academic science would be decimated by the movement into industry.

Some academic scientists responded by defending the old ideals of pure, non-commercial research. The physicist in a college or university had his own rewards. "Financially his lot is not a wealthy one," as one of them admitted "nor socially is he high . . . [But] Close to nature and by it closer and closer every day to the Almighty God who made him, what matters it to the physicist if the days be dull or neighbouring man uncouth? His soul is more or less aloof from mortal strife"[15]. In short, it was all very well to go into industry if money was your object, but there was still something morally superior about the life of academic research.

In the end the schools were not drained but strengthened by the growth of industrial physics. For it was far less the established physicist who was snatched up than the new graduate. This meant that industry was supporting an increase in student enrolments which must have had much to do with the overall rise of academic physics departments between the two World Wars. Many physics teachers felt that their departments would be strengthened by attracting students destined for industry. Applied physics courses or programmes, sometimes labelled "engineering physics", were set up by physicists at a number of schools in the early and mid-1920s.

Industry took not only undergraduates trained in physics but also PhDs. Around 1900 only a tenth of the few PhDs graduating each year in the USA wound up in industry; in the 1920s about a fifth of the ever increasing number of new PhDs were going into industry (my calculations: the sample of new PhDs was drawn from ref. 16. For convenience I used Marckworth's original file cards, at AIP. Locations from *Bull. Am. Phys. Soc.*, and Cattell, J. M., *American Men of Science* (Science Press, New York, 1906–1944)). For research—where the quality of the personnel is everything—the leaders of industrial laboratories had concluded that the best workers were those with graduate training. To select and attract these recruits they had to have close contacts with the professors who were training students. This made for strong ties between industry and the campuses[17].

This also gave industry a new motive for supporting research in the universities. Through such support a company could keep its eye on promising young men while at the same time keeping abreast of scientific developments. For example, Corning Glass sponsored fellowships and research at Cornell, Illinois, MIT and Purdue on problems of chemical physics directly related to glass making. Such arrangements were probably rather common. In the absence of outright fellowship or grant support, a company could still contribute in smaller ways and keep up close relations; among the acknowledgments in papers published in the *Physical Review* in the 1920s one finds frequent thanks given to companies for the loan or construction of pieces of apparatus or the use of their laboratories.

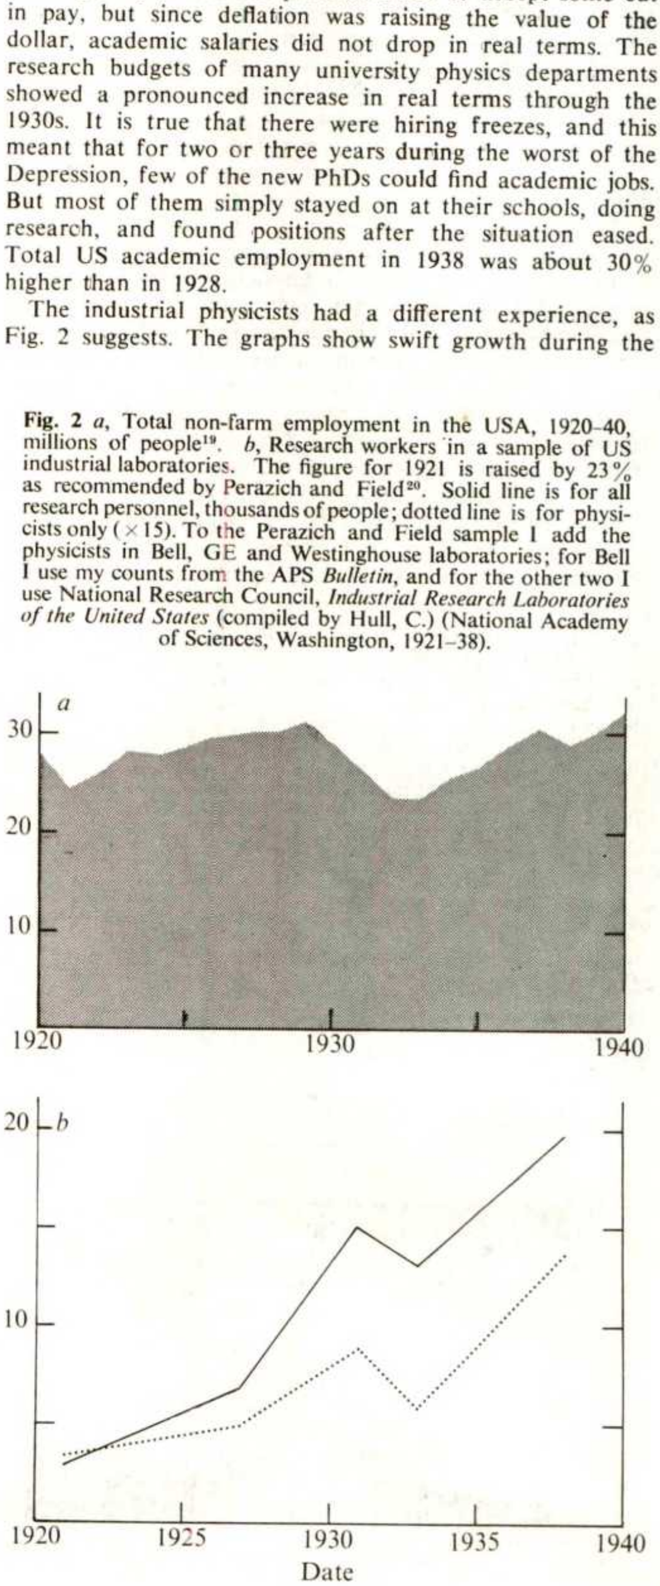
All this led some to feel that the universities were "beginning to be led by the industries, instead of vice versa" (Pupin[18] apparently regarded this trend favourably). But in so far as the point was to train researchers, the exact nature of the research was secondary. Freedom of inquiry in universities was not seriously infringed on by the support industry gave; rather the possibilities for inquiry were broadened all around.

So it seemed that all was going well, and that aside from minor jealousies American physicists, industrial and academic, were advancing hand in hand in uninterruptible progress. Then came the Great Depression. When a system is struck by a heavy shock, we may hope to learn something; by listening to the seismic echoes we may study hidden internal structures. The Great Depression gives us an opportunity to do this for American physics.

The first thing to note is that academic physics did not suffer greatly. Often the professors had to accept some cut in pay, but since deflation was raising the value of the dollar, academic salaries did not drop in real terms. The research budgets of many university physics departments showed a pronounced increase in real terms through the 1930s. It is true that there were hiring freezes, and this meant that for two or three years during the worst of the Depression, few of the new PhDs could find academic jobs. But most of them simply stayed on at their schools, doing research, and found positions after the situation eased. Total US academic employment in 1938 was about 30% higher than in 1928.

The industrial physicists had a different experience, as Fig. 2 suggests. The graphs show swift growth during the

Fig. 2 *a*, Total non-farm employment in the USA, 1920–40, millions of people[19]. *b*, Research workers in a sample of US industrial laboratories. The figure for 1921 is raised by 23% as recommended by Perazich and Field[20]. Solid line is for all research personnel, thousands of people; dotted line is for physicists only (× 15). To the Perazich and Field sample I add the physicists in Bell, GE and Westinghouse laboratories; for Bell I use my counts from the APS *Bulletin*, and for the other two I use National Research Council, *Industrial Research Laboratories of the United States* (compiled by Hull, C.) (National Academy of Sciences, Washington, 1921–38).



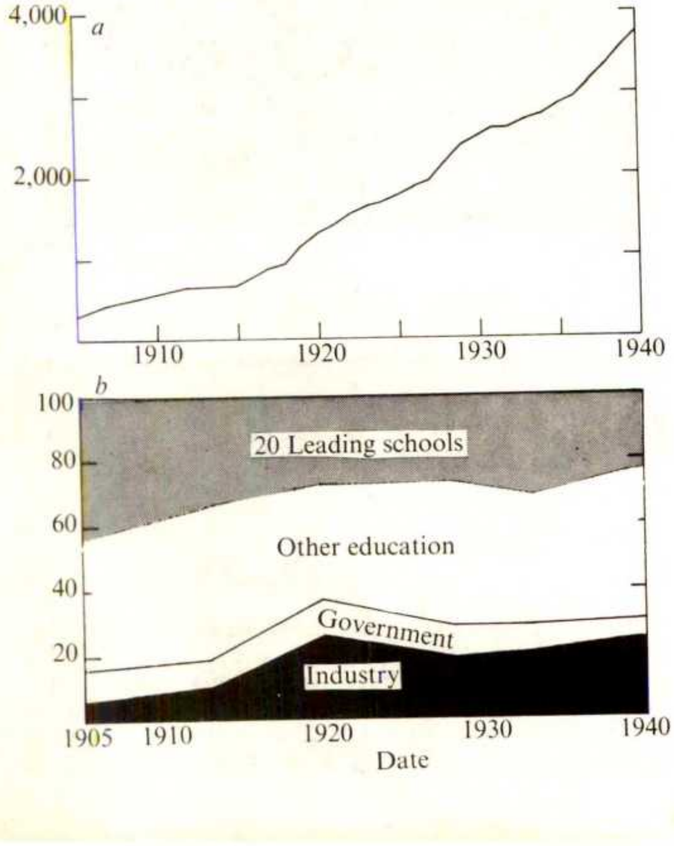
1920s, a terrifying plunge during the Depression—as bad as the general collapse of employment in the USA—and then recovery. Data on budgets are harder to come by than data on personnel, but they apparently followed a similar curve. In particular, the most important single employer of physicists in the USA, ATT, cut its research and development budget by over 25% in constant dollars from 1930 to 1933, but by 1939 this had recovered and was more than 10% higher than the 1930 figure (figures for 1916–35 are from ref. 21 and for 1939 from ref. 22).

Suffering from direct and indirect pay cuts, watching friends being laid off, for a few years the applied physicists had a hard time. The director of the General Electric laboratories suffered a nervous breakdown which the Depression was said to have helped bring on[23]. For the moment it seemed, as one industrial physicist declared in 1935, that "the era, or rather wave of industrial physics [had] subsided"[24].

But physicists in industry were spared the worst. In many laboratories research, including basic research, continued without interruption. The recovery shown in Fig. 2, so much stronger than the recovery of employment generally, also indicates a special position for industrial research. The net rise in the employment of physicists in industry from 1930 to 1938, ignoring what happened in between, was proportionally comparable to the rise in academic employment over the same interval. A large part of this swift recovery—perhaps as much as a third of it—was due to the exploitation of a new application for phyics: the use of geophysics in the oil industry. Gravimeters and seismographs greatly aided geological prospecting; thus physics research helped enlarge its own field of employment.

In the 1930s as in the 1920s, the employment of new physics PhDs provided an important connection between the campus and industry. The job problems of new PhD physicists were in large part due to hiring freezes in the academic world, but the collapse of industrial employment exacerbated their difficulties. Of 110 physicists who got their PhDs in 1928 and 1929 and whose location can be determined from the 1930 membership list of the American Physical Society, 24 were in industry and four more in government; but of 63 who got PhDs in 1934 and who are found in the 1935 list, only four were in industry and none in government. The rest were virtually all in academic institutions (my calculations from ref. 16). This decline did not escape the attention of the professors who sent the students forth.

Fig. 3 *a*, Membership of the American Physical Society, 1905–40. *b*, Location of employment of American Physical Society members, as percentage of those whose employment can be inferred from their addresses and was in the USA. From top to bottom the areas refer to the twenty universities with strongest physics departments; all other "education" including non-profit institutions; government; and 'industry' including business, medicine, and miscellaneous.



Academic physicists noted that there were applied fields to which physics could contribute but in which industry did not seem to be using the opportunity. Professors began working to persuade industrialists to employ physicists, and to train physics students so that the industrialists would want them. "A going concern must find a market for its product," one academic pointed out, "and this is true of the profession of physics"[25]. A leader of the physics community was equally blunt: "The number of teaching jobs available for physicists will always depend on the number of students taking physics. We know that the number of these students will increase if it becomes clear that there are industrial opportunities for them"[26].

Critics, industrialists and professors alike, charged that teaching was directed too much towards producing a new generation of teachers. The introduction of modern theoretical work into American university physics, which had been a prominent trend in the 1920s, did not impress these critics; what the physics graduate needed, they said, was less work with quantum mechanics and more with classical physics and a slide rule. Physicists feared that this sort of training was being usurped by the engineering faculties, whose graduates more and more resembled the product of the physics departments. To see how the universities were meeting these problems, physicist Henry Barton wrote letters to a number of physics departments at the end of 1935. He found that about half of them had taken, or were seriously planning to take, steps to increase the attractiveness of their students to industry[27]. Not all schools joined this movement, and at any rate the majority of students continued to end up with academic jobs. But at certain schools a majority of the physics PhDs who graduated in the 1930s found their homes in industry.

We have noted that the movement to teach applied physics in the universities included some elements of a reaction against pure and theoretical physics. The conflict also came to the fore in another theatre, the physics societies. Figure 3 analyses the chief of these, the American Physical Society. Figure 3*a* shows the growth of society membership from 1905 to 1940. The effects of the Depression, or even the First World War, on this curve would be difficult to prove. The breakdown of the membership (Fig. 3*b*) shows what percentages were in various locations. The shaded areas at the top, education (including private non-profit research institutes) dominate throughout. But there is a significant change in the proportions employed by industry (the black area) and by government (the white). Their combined total grows strongly into the 1920s and then drops off. Note that because of the rapid growth of the American Physical Society as a whole, the absolute number of applied physicists in it was higher in 1940 than in 1920; but they were never again so large a proportion of the total as they were in the 1920s, the golden age of applied physics research.

People noticed that not all those who might be called physicists were members of the American Physical Society. Many belonged to the engineering societies and called themselves engineers, even though their work was in direct application of physics research. In fact, of the 1,500 or 2,000 so-called physicists in industry in 1938 only about half were in the American Physical Society. The reason was that applied physicists were coming to feel themselves set apart from those in pure physics. "We did not feel at home in the Physical Society meetings," one of them recalled. "I once read a paper before the Physical Society, and I am sure the Physical Society was not interested in the paper"[28]. These feelings had gained strength through the 1920s as the numbers of applied physicists grew and as they noticed that the society was becoming more concerned with quantum mechanics and atomic spectra than with physics in the broadest sense. Already in 1916 the Optical Society of America was founded by a group at Eastman Kodak; in 1929 the Acoustical Society of America was founded at Bell Laboratories and the Society of Rheology was founded by people interested in the study of plastic materials. In 1930 there were rumours that a Society of Applied Physics would be created[29]. The trend seemed to be towards a complete schism in the physics community.

This was avoided by the founding in 1931 of the American Institute of Physics, which undertook operations such as publishing and public relations which were most efficiently done jointly. Throughout the mid-1930s this organisation had a leading role in bringing industrial and academic leaders together, in trying to explain the value of physicists to industry and the value of industry to physicists, and in working to persuade applied physicists to stay within the fold. Several conferences were held with joint academic–industrial participation[30–32]. "To those of us who have been engaged in industrial research," one physicist wrote in 1937, "... there appears to have been a social upheaval in the realm of the physical sciences in which the researcher in practical or applied fields has been lifted from the gutter of so-called 'prostituted' science and at least his better qualities held up as ideals for aspiring young physicists to emulate"[33].

The actions of academic physicists during the Depression period, through new curricula and new organisations, shows great sensitivity in the area of applied physics. If the professors were not all wrong, then this sensitivity is evidence that any weakening of applied physics or of its ties to the academic world would have been a heavy blow to all physics.

Fortunately, as we have seen, industrial physics recovered. Towards the end of the 1930s there were even hints that the most abstract physics of the universities might have some value for industry after all. General Electric advertised for a quantum theorist to look into the fundamental quantum processes involved in fluorescence, as in fluorescent lights; people at the Bell Telephone laboratories studied the quantum theory of solids, setting out on the path that would lead to the transistor; Westinghouse went into nuclear physics, a subject which later became one of its major fields of industrial interest.

In conclusion, the experience of the Depression indicates that the greatest strength of American physics still lay in the academic sector. But the anxious reaction of academics to the situation in industry suggests that a strong industrial research establishment had become as necessary, in the long run, to the universities as the universities had become to industry.

Finally, the situation has not changed greatly from the 1930s to the present day. For example, in 1973 some 53% of American PhD physicists worked in the universities, 24% in industry, 11% in government and 12% in federally funded research and development centres[34,35]. Except for the growth of federally funded centres at the expense of the universities, this is about the same as the situation before the Second World War. The relationship between academic and industrial physics research in America, established during the first four decades of the century, has proved as stable as it has been fruitful.

I thank Tessie Liu for research assistance.

Population studies and the Old Order Amish

Harold E. Cross

Section of Ophthalmology, University of Arizona, College of Medicine, Tucson, Arizona 85724

Populations of Old Order Amish, living in Pennsylvania, Ohio and Indiana, and isolated by their strict religious views, have provided human geneticists with a rich source of data.

LIFESTYLES in the United States, as in many other countries, have changed remarkably during the past 200 yr. Technological advances, with improved transportation and nearly instantaneous communication, have probably had the most significant impact on our social structure and cultural evolution. With progressive industrialisation and the need for highly specialised skills, these factors have contributed to the decline of relatively self-sufficient, isolated agrarian communities in which the nuclear family comprised the basic living unit. These have, of course, been replaced by large conglomerations of interdependent, amalgamated, and highly mobile masses to which the "melting pot" metaphor is perhaps more aptly applied than during the early days of settlement.

Nevertheless, certain segments of the US population have remained relatively unaffected. In some circumstances, the trend has been at least partially countered by cultural ties or economic restrictions as in the case of the ethnic and ghetto neighbourhoods of major metropolitan areas. In others, geographic barriers such as the Appalachian mountains of the eastern USA and the marshy bayous of the deep south, have effectively excluded these socioeconomic influences. Among the triracial isolates scattered throughout the eastern coastal states, racial barriers have prevented assimilation by restricting matings to individuals with a mixture of Indian, Caucasian and Negro ancestry.

The value of insular populations has long been recognised by human geneticists. Lacking the luxury of a highly proliferative species such as *Drosophila*, or the benefits of controlled breeding experiments available to a mouse geneticist, they are instead dependent on nature to provide the appropriate human population model. Human isolates, separated as they are from the prevailing cultural mores, often have at least some of the desirable characteristics of the biologist's experimental model. Many have large families, thus making available larger numbers of progeny for study. Social or religious taboos frequently limit dilution of the gene pool by restricting matings to members of the group. Such populations are often geographically concentrated due to their limited mobility and identification is facilitated by peculiarities of custom or dress.

Genetic aspects of isolates in industrialised countries have, however, received relatively little attention. Clinical investigations in Europe[1] and Scandinavia[2], as well as North America[3] have contributed significantly to the understanding of selected heritable diseases, and, in some instances, revealed "new" disorders. Other isolates in North America have been the object of demographic[4] and immunological[5] studies. In 1963, Hostetler[6] published the first major sociological study of the Old Order Amish whose unique features were immediately recognised by McKusick[7] as useful for genetic studies. Through their collaboration and that of others during the next decade, the Amish have become the most extensively studied isolate group in the USA.

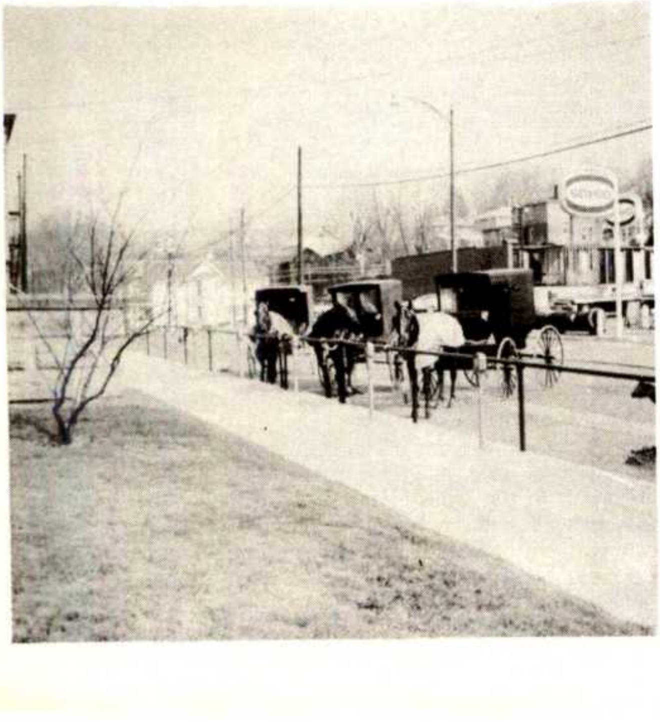

Fig. 1 North-east view from Millersburg, Ohio courthouse showing Amish horse-and-buggies tied to rails at parking meters. This blend of tradition and modern technology illustrates the accommodative attitude of non-Amish toward their unusual, isolationist Amish neighbours who, in turn, patronise "worldly" businesses without becoming assimilated.

The Amish constitute one of several religious factions classified as Anabaptists because of their opposition to infant baptism. Unlike all other Anabaptist sects, such as the Mennonites, Dunkards, Amish-Mennonites, and Beachy Amish, the Old Order Amish hold religious services in their homes rather than in churches or meeting houses. Although this unique feature absolutely distinguishes them, other characteristics make tentative indentification possible. Perhaps none is more conspicuous than their eschewal of technological innovations. Electricity and telephones are not allowed in their homes although in communities where Ma Bell has enterprisingly placed payphones in strategic locations, at least some Amish freely take advantage of the opportunity. The use of petrol engines is likewise forbidden, but curiously, steam is an acceptable, albeit rarely used, form of energy. This limitation, plus the interdiction of pneumatic tyres, has restricted transportation to the horse-and-buggy so familiar in their communities (Fig. 1).

All Amish are rural living and nearly all are farmers. They are highly clannish and have a strong interest in their ancestry and genealogical relationships. This has stimulated the publication of numerous genealogy volumes by which the ancestry of most members can be traced to the original immigrants. Perhaps most importantly, this simple folk society has somehow managed to resist assimilation and annihilation through strong internal disciplinary measures, including the practice of "shunning" or *Meidung*, by which transgressors are totally ostracised.

To the casual observer, however, personal appearance is the most striking peculiarity of these "plain-clothes people". Any form of personal adornment, including brightly coloured clothes, is strictly forbidden. All external clothing is handmade by the women from plain brown, blue or black fabrics. "Barndoor" trousers held up by suspenders and jackets with hook-and-eye fasteners are worn by the men; women's dresses are fastened with straight pins. Hair style for males is a uniformly cut, medium length, 'upside-down bowl' style (embellished with a beard without moustache after marriage), whereas females are forbidden to cut their hair. Instead, they wear it rolled up into a bun, covered with a prayer veil during all waking hours.

The Amish originated in the Canton of Berne, Switzerland, when followers of Jakob Ammann split from the parent Swiss Anabaptist sect between 1693 and 1697. Other converts came from eastern France, the Palatinate and Alsace–Lorraine. Never fully accepted in Europe, and viewed by their fellow citizens as rather peculiar, many Amish were strongly tempted by the religious freedoms promised in America. Immigration began perhaps as early as 1714 and continued for nearly 125 years. The first immigrants, mainly Swiss and numbering approximately 200, settled in eastern Pennsylvania as founders of the present group known as the Lancaster Amish. After about 1770, however, new immigrants, primarily from Alsace–Lorraine and nearby areas, found Pennsylvania too crowded and moved further west, chiefly to Ohio. The Holmes and Geauga County, Ohio Amish in the mid-nineteenth century became, in turn, the primary source of founders for the third major concentration of present-day Amish which is centered in Lagrange County, Indiana. Although Amish populations are now located in approximately 20 states, and a few recent attempts have been made to establish populations in the Honduras and South America, about 80% of the nearly 50,000 practising Amish live in the three states mentioned above. Migration and religious persecution eliminated all Amish from Europe.

The Amish are strictly endogamous, do not proselytise, and "outside" marriages with non-Amish are strictly forbidden. These restrictions, together with the limited number of founders, has led to a relatively high mean coefficient of consanguinity ($F = 0.00769$ in the Holmes County group), equivalent to second cousins once removed. In addition, however, their limited means of transportation, subtle differences in religious practices, and, in the case of the eastern Pennsylvania and Holmes County, Ohio groups, separate origins have effectively produced subisolates. For example, eight surnames account for 81% of the Lancaster Amish population whereas 77% of the Ohio Amish have a different set of eight surnames. The continued isolation of these two communities is illustrated by data from an analysis of 2,013 Holmes County couples living in 1966: only two partners came from Lancaster County. Such isolationism is evident even among Indiana and Ohio Amish with much closer ancestral and religious ties: only 116 marital partners left Indiana to join their mates in Holmes County, evidence of separation which no doubt portends even greater genetic dissimilarities in the future.

Interestingly, in spite of their usual pacifism and strong belief in non-violence, there is considerable internal strife. New religious factions are constantly being formed and dissolved. In Holmes County, for example, two groups known as the Stutzman and Stolzfus Amish split from the parent body in the early 1960s and marriages between any of the three groups is actively discouraged. If this practice persists, new genetic isolates may be formed.

The Amish community is primarily a spiritual one without distinct geographical boundaries. Amish farms are scattered throughout the rural communities, often sharing borders with non-Amish farms. Their religious charter, however, effectively prohibits social and cultural interaction with the non-Amish community with the result that their demographic characteristics[8] are quite distinct. As a result of their high crude birth rate (33.3 compared with 21.2 for the entire USA in 1964), the population pyramid[8] has a relatively broad base; 51.8% are less than 20 yr old and 28.7% are less than 10 yr old. The pyramid tapers more smoothly than that for non-Amish populations since their self-sufficient agrarian lifestyle renders them relatively independent of the cyclic effects of political, economic and social stimuli. Most men (69.8%) are farmers, at least in Holmes County where the most complete data have been collected. A further 13% are self-employed in supporting trades such as carpentry, blacksmithing, harness repairing and construction.

The Amish marry at a considerably later age than their rural counterparts (22.57 yr for a female, and 23.61 yr for males). Because of the obvious economic advantages of large families in a rural setting, and their strict interpretation of the biblical admonition to "be fruitful and multiply", children are considered highly desirable. Contraception, although not prohibited, is viewed as undesirable with the result that the female reproductive span is longer and birth intervals shorter than among other US rural populations. Among 792 completed Holmes County Amish families (in which the wife was at least 45 yr old), the mean number of pregnancies was 7.19 and more than, one-third (34.8%) reported 10 or more pregnancies. The net result is an intrinsic rate of natural increase (r) of 3.019 or a potential doubling of population size every 23 yr. Among modern North American isolates, only the Hutterites were found to have a higher rate ($r = 4.1265$). This increase is not achieved for the Amish, however, because there is a substantial attrition rate among young people who are lured away by the 'outside world'. Still, it is obvious that the Amish could lose four or five times the 10–15 % estimated to leave each generation, and still maintain their population size at the present reproductive rate.

Curiously, Holmes County Amish men tend to outlive their wives. The sex ratio in this population for those over the age of 55 yr is 1.216. Similar trends have been noted in other high fertility groups such as the Hutterites and northern Indiana Amish, giving rise to speculation that the emotional and psychological stresses of childbearing may have an adverse effect on longevity.

It is apparent that the Old Order Amish have several attributes that make them useful to human geneticists. Members are easily identified by their distinctive dress and customs. Their communities were founded by a limited number of ancestors, with identifiable origins. They maintain a closed population with virtually no dilution of the original gene pool. Families are large, illegitimacy rates are low, and the membership constitutes a relatively immobile society concentrated in specific geographical areas. Several additional features are of particular value to the medical geneticist: relatively stable socioeconomic values, uniform environment, high standards of living and medical care, a great interest in medicine, and strong resistance to institutionalisation of the chronically ill.

Table 1 Distribution of some rare recessive genes in the Old Order Amish

Isolate	Recessive disorder
Mifflin County, Pennsylvania	Pyruvate kinase-deficient haemolytic anaemia[9]
Lagrange County, Indiana	Phenylketonuria[10,11]
Lancaster County, Pennsylvania	Ellis–van Creveld syndrome[12]
Adams and Allen Counties, Indiana	Limb-girdle muscular dystrophy[13]
Holmes County, Ohio	Mast syndrome[14]
	Troyer syndrome[15]

Populations founded by a small number of ancestors may exhibit an unusually large number of otherwise rare hereditable traits if the founders carried a frequency of mutants that differed widely from the parent population. If the population further remains 'closed' by excluding matings with outsiders, the purity of the original gene pool is maintained, and the restricted number of available mates results in a high rate of consanguinity. Since consanguineous couples share ancestors, they are likely to inherit at least some identical genes, and chances are good that their offspring will inherit the "double dose" of mutants necessary for the expression of recessive disorders. These conditions were apparently satisfied in the case of Amish settlements since all of those studied have at least one recessive disorder occurring with relatively high frequency (Table 1).

The limited distribution of these genetic diseases is another indication of genetic isolation. Only one recessive disorder, a "new" type of dwarfism (cartilage-hair hypoplasia), seems to occur throughout most Amish communities including Holmes, Lancaster and Lagrange counties as well as among smaller settlements in Iowa, Oregon, Kansas, Illinois and Michigan[16]. Either the origin of this gene was more ancient, antedating the origin of the sect, and was introduced by multiple immigrants, or the descendants of the person or persons who introduced it were unusually nomadic.

The peculiar social and cultural restrictions of Amish life also make them useful for epidemiological and population studies. Certain aspects of the distribution of cervical cancer, for example, raises the suspicion that it might be a venereally transmitted disease. Women with increased risk are those with marital instability, early coitus or early marriage, multiple coital partners and other venereal infections. Under this hypothesis, groups with low risk for cancer of the cervix would practice (1) strictly endogamous matings (to avoid introduction of the responsible agent), (2) monogamous sexual behaviour (restricting the agent), and (3) strong group boundaries over many generations. These are, of course, characteristics of the Amish, maintained and enforced by their religious taboos. Divorce is forbidden and separation is extremely rare. In either case, marital infidelity is virtually unknown, although premarital conceptions probably occur with a frequency similar to other US populations. In most cases, however, the biological parents do become married with the result that the overall illegitimacy rate is low. Among 1,098 Amish offspring of 155 couples in northern Indiana, no paternal exclusions were found by ABO, Rh and MN blood group determinations[5]. Furthermore, their strict moral standards regarding marital fidelity and their condemnation of divorce limit the transmission of other venereal diseases, according to local physicians.

Table 2 ABO blood group frequencies in three Amish isolates

Blood group	Holmes County isolate*	Lancaster County isolate†	Adams County isolate‡	Random AngloSaxon population[19]
O	0.34	0.11	0.16	0.45
A	0.54	0.74	0.65	0.41
B	0.06	0.05	0.11	0.10
AB	0.06	0.11	0.08	0.04

*n = 1,027; ref. 18.
†n = 215; ref. 18.
‡n = 892; ref. 17.

Use of the Amish to test the possibility of venereal transmission of cervical cancer is especially valuable because its frequency among them can be compared with that found in non-Amish living in the same area where medical care practices are similar and the effect of economic and environmental factors is largely cancelled out.

A retrospective study in Holmes County, Ohio, based on 10,314 Papanicolaou vaginal smears obtained between 1950 and 1966, revealed a significantly lower frequency of cervical cancer in Amish women. Among 3,606 non-Amish women, three died of cervical cancer (a frequency similar to other rural populations) whereas none of the 2,068 Amish women examined died of this disease. These data are even more interesting because the Amish have several characteristics associated with high risk groups, such as a high rate of reproductivity, absence of contraception, and a low rate of circumcision (at least among older males). In view of the similarities of economic standards and medical care practices between the two groups, it seems plausible to attribute the difference in frequencies to some aspect of social or cultural behaviour. Social isolation and reduced sexual contacts between Amish and non-Amish might, therefore, account for the reduced rate of cervical cancer if it is caused by a venereally transmitted agent.

Blood group data are widely used by population geneticists in the study of evolution and genetic similarities of various groups. To further document subisolate formation among the Amish, ABO frequencies for three communities were determined. Blood was collected systematically from the Amish isolates located in Adams County, Indiana[17] and Lancaster County, Pennsylvania[18]. For the Holmes County community, however, extensive data already available were used by taking advantage of the fact that Amish do not have telephones. Due to their interest in medical illness and the relatively high frequency of haemophilia B (Christmas disease), Amish in this area give blood freely. Red Cross donor cards were compiled on all citizens of the area and Amish individuals identified by characteristic surname on cards without a telephone number. ABO frequencies among the three populations, as well as a random Anglo-Saxon sample, are compared in Table 2. It is apparent that the Amish not only differ from non-Amish in ABO frequencies but they evidently maintained significant isolation from each other.

In spite of their apparently effective isolation from the external world, and evident internal stability, the Amish exhibit signs of stress that may indicate their eventual acculturation, at least to some degree, with the larger rural community. Demands for higher education and restlessness among young people seem to be increasing. Pressure for relaxation of rules against the use of mechanical devices such as tractors and automobiles by older individuals is responsible for considerable internal strife and fragmentation. At the same time, rising costs and, in some areas, decreasing availability of good farm land is forcing many to resort to marginal, non-farming vocations, bringing them into closer contact with worldly temptations. Nevertheless, their reproductivity and strong internal sanctions make it unlikely that this unique society will disappear in the near future. In the meantime, these peculiar people have provided us with an unusual opportunity to study the genetic and epidemiological aspects of human disease to a degree that will be increasingly difficult to achieve among the modern population.

Scientific networks in the age of the American Revolution

Arnold Thackray

Department of History and Sociology of Science, University of Pennsylvania, Philadelphia 19174

The channels of communication between scientists in the UK and USA during the late eighteenth and early nineteenth centuries, the growth in importance of the provincial centres and the relative position of London, are reviewed in the light of the social, cultural and political moods of the time.

"THE rights and liberties of our countrymen in America are much less dear to us than they ought to be." The words were those of a rising Manchester physician, in a June 1774 letter to a well known Philadelphia printer. The physician's concern encompassed more than remote, colonial affairs. The situation at home also gave cause for alarm. "The principles of despotism in our Governors and of passive obedience in the people seem to be advancing by an equal and alarming progression." These opinions were shared by other influential Mancunians, including a manufacturer who wrote some nine months later to Philadelphia's foremost physician, saying "I sincerely regret, from more general considerations than my own interest, the unhappy divisions that prevail between the mother country and her colonies. Soon may they again be united, and may their quarrels like those of lovers, tend to confirm and strengthen the mutual affection which ought to subsist between them."

The exchange of such sentiments was halted abruptly by the onset of the War of American Independence. It was almost ten years before the manufacturer wrote again, marvelling "how strange and unexpected have been the events . . . (causing) so long and unfortunate an interruption to our correspondence." He went on to say that "tho' separated and become subjects of different states, I trust that every spark of affection is not extinguished, or at least that individuals will renew and maintain their pristine attachments." The hope was expressed in the formal language and cast in the individualistic terms of the period. As events were to show, the hope was also eminently realisable, and a clue as to why may be found in a third letter. It was in September 1786 that the then premier physician of Manchester confided to his counterpart in the City of Brotherly Love: "I shall be happy in every opportunity of promoting a friendly and philosophical intercourse between my countrymen and the literati of America. The arts and sciences are the offspring of freedom; and I cordially rejoice that your noble exertions have secured to you these invaluable offspring."

The scientific network

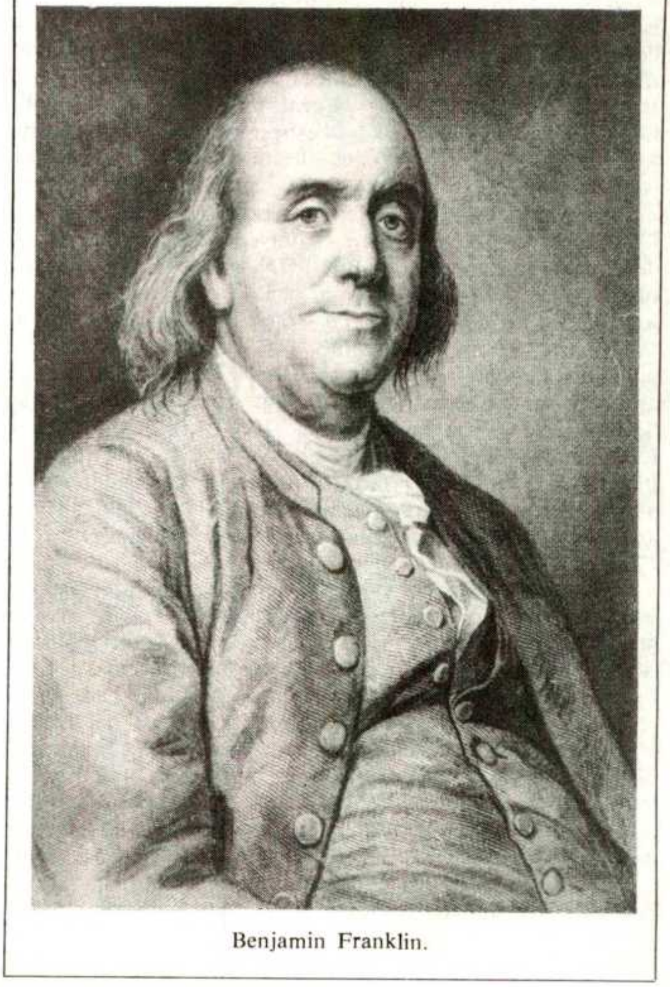
The series of letters from which these quotations come provide us with a glimpse of an important scientific network of the late eighteenth century. The correspondents—Benjamin Franklin, Thomas Henry, Thomas Percival and Benjamin Rush—were all major figures in their day, as was Joseph Priestley. Franklin's work in electricity is well known, as is Priestley's discovery of oxygen. Thomas Henry was also influential in the chemistry of the period, publishing translations of the work of Antoine Lavoisier in 1776 and 1783. Percival in his turn was active in chemistry and meteorology, and was a pioneer of mortality statistics. He composed a standard work on *Medical Ethics*. Finally, Rush was not only a chemist and physician of note, but also a leading medical and psychiatric theorist. Each of the five participated actively in one particular link in the network of provincial, rationalistic dissent.

Other scientific networks, each encompassing its own appropriate linkages, were also significant in this era. Two come to mind as especially important. Most immediately and most obviously, the affairs of the Royal Society of London, and of much else besides, were quite unselfconsciously controlled by the members of a network that linked together the metropolitan elite, the English universities and certain interested and influential country gentry. One reason that Sir Joseph Banks was able to entrench himself as President of the Royal Society and thus to serve for the record span of almost forty-two years (November 1778–June 1820) was because he exemplified in himself the three elements of this central network of the late eighteenth century. The third network, connecting with but quite distinct from the previous two, was the one that centred on the scientific interests of the Scottish nation. Its members came from the ranks of Scotland's 'improving' landlords, from among the professors at her several universities and from those native-born students who emigrated to England and her dependencies in search of wider opportunity.

Analytically, we normally separate the science, the politics, the philosophy and the religion embraced by such men and involved in such networks, and treat each by itself. If, instead, we view the cultural values, social functions and intellectual commitments involved in more holistic fashion, we may understand better not only the ways in which images of science, progress and freedom were woven into the fabric of the American Revolution, but also the functions of scientific networks in the preindustrial age. The particular case of provincial, rationalistic dissent, as seen in the microcosm of the Philadelphia–Manchester link, may illuminate the macrocosm of social structure, political change and the growth of knowledge. Equally, our understanding of the macrocosm may help us comprehend what we see revealed in the microcosm.

London as a focal point

By the mid-eighteenth century, London was Europe's largest, richest, most complex and most cosmopolitan city. In population it was soon to outrank its nearest rival, Paris, by a factor of more than two. Within the English-speaking, as opposed to European, world, London's pre-eminence was even more pronounced. No other English-speaking city was one tenth of its size. Advantages of scale were reinforced by the city's commercial, financial, intellectual, legal, political and social significance as the centre of a newly united Britain and of a dawning empire. The Royal Society of London for Improving Natural Knowledge was thus in an enviable situation. A metropolitan elite of peers, gentlemen of independent means and successful physicians, clergy and lawyers gave tone and direction to its activities. Foreign ambassadors and visiting princes attended its sessions. Lowlier but more earnest visitors from the colonies, the provinces and the lesser metropolises of Dublin and Edinburgh brought information, specimens and favourite but unwinnowed ideas. On returning home they took not only tested knowledge and new theories, but heightened aspirations and fresh models of behaviour. Benjamin Franklin was one of 53 American colonists who became an FRS. Thomas Percival, Thomas Henry and Joseph Priestley were among the larger, but uncounted, group of English provincials who succesfully sought the heightened social standing and envied cosmopolitan connections implicit in the Fellowship. The subsequent ostracism of Priestley provides a vivid example of how member-



Benjamin Franklin.

R 388

ship still left one a likelier candidate for neglect than for office within what was correctly called the Royal Society of London.

Importance of provincial centres

Those on the provincial and colonial peripheries of the eighteenth century social world naturally sought approval from the centre and conformity with its values. Dissent was an alternative which was, however, sometimes as attractive as assimilation. Ambivalence between the two marked the growing mercantile communities of provincial cities from Birmingham to Boston. This ambivalence ensured good connections between provincial, rationalistic dissent and the central scientific network on the one hand, while also encouraging connection with Scottish science on the other. Those who literally dissented in central, religious values were of course, barred from graduation at either English university. Edinburgh provided a favourite locus for such dissenters. Its different devotional traditions and its own particular ambivalencies about English norms gave promise of congenial context. The varied clubs and institutions of the town and most especially its rapidly-growing university served as centres of socialisation into alternative values. Within the university itself, the medical school offered not only appropriate direction but also coveted certification for a burgeoning line of service and opportunity. Thomas Percival and Benjamin Rush both studied there. Percival later went so far as to secure an Edinburgh doctorate (of law) for his friend and mentor, Joseph Priestley (Priestley in his turn had sponsored the youthful Percival before the Royal Society).

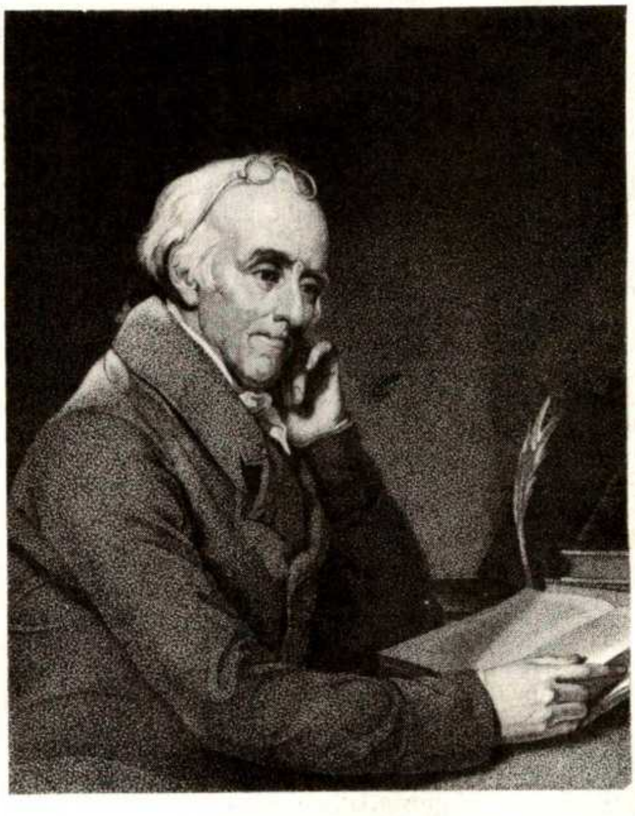
Edinburgh-trained physicians were drawn to the new medical opportunities apparent in the 1750s and 1760s in such rising provincial towns as Philadelphia, Manchester, Liverpool, Bristol, Boston and Birmingham. Most dramatic is the case of Philadelphia. The city was beginning to develop its own intellectual life and to serve as centre for the scattered seaboard communities of British North America. It was thus the natural site for the continent's first medical school. Like Rush and its founder John Morgan, its earliest professors all enjoyed Edinburgh MDs. Custom and the reach of law as institutionalised in the monopoly power of Oxford, Cambridge and the (London) College of Physicians were sufficient to preclude such developments in England. But MDs with Scottish training played influential, if less formal, roles in provincial English towns, serving as nuclei round which social forms oriented to natural knowledge, polite behaviour and advanced political thought might crystallise. Their influence is apparent in the development of, among others, the Lunar Society of Birmingham (about 1765), the Manchester Literary and Philosophical Society (1781) and the Derby Philosophical Society (1783), as well as in the cognate cases of the American Philosophical Society (Philadelphia, 1769) and the American Academy of Arts and Sciences (Boston, 1780).

Medical men of all kinds, including apprentice-trained surgeons and apothecaries, were a key element in the growing eighteenth-century network of rationalistic, 'scientific' dissent in both its provincial and colonial forms. Family connection and religious conviction also had major roles. If Edinburgh-trained physicians were the shock troops of the movement, dissenting ministers of a Socinian turn of mind served as its theorists; the most notable of these was Joseph Priestley. Between his electrical investigations and his brilliant discoveries of ever more curious sorts of "air", he produced endless polemical broadsides on theology and served as a 'culture hero' to a generation. Priestley was directly associated not only with the Lunar Society and the Manchester Literary and Philosophical Society but also, eventually, with the American Philosophical Society. Less spectacular but more typical was the Turner family. William Turner was a Unitarian minister and an early member of the Manchester Literary and Philosophical Society. Using this as a model, he founded the Literary and Philosophical Society of Newcastle upon Tyne (1793), which he served as secretary for over forty years. His son later fashioned a similar 'Lit and Phil' in the burgeoning industrial town of Halifax.

Other examples of the connections between medicine, rationalistic dissent, merchant activity, manufacturing concerns and family lineage spring readily to mind. The Lunar Society provided a nexus for Darwins, Wedgwoods and Witherings to enjoy polite conversation, pursue natural knowledge and forge marriage alliances. Erasmus Darwin founded another Philosophical Society when he moved away to Derby in the early 1780s, and was promptly rewarded by election as an honorary member of the Manchester Society. As late as 1817–18 his grandson, Charles Darwin, attended a Unitarian school before arrangements were made for him to follow family tradition by reading medicine in Edinburgh. Finally, we note how a group associated with the Manchester Literary and Philosophical Society even went so far as to plan a pantisocracy in Pennsylvania when, following not only the American but the French Revolution, the political climate in England turned decisively against progressive, rational dissent. The movement to Philadelphia in 1794 of Thomas Cooper, Thomas Henry, Jr and the Joseph Priestleys, both senior and junior, may be seen as a last efflorescence within these eighteenth-century forms. (The first of the foursome obtained, the second unsuccessfully sought, and the third declined, a scientific chair within the University of Pennsylvania.)

The network and the revolution

The American Revolution symbolised the coming end of the symbiosis between provincial and colonial values. The path



Benjamin Rush.

of development in the USA was to be one in which Americans painstakingly, precariously and long unsuccessfully sought to redefine "their" centre from London to somewhere—no one could agree where—in the new nation. Not until 1863 was an enduring National Academy of Sciences founded; not until the first World War did that Academy become a main voice in American science. The modes of federalism and pluralism developed in the USA contrasted strongly with the trend to centralism in British life. In the course of the nineteenth century the UK became a tightly integrated whole. The nature of that integration was neatly echoed in the new forms of science. The British Association for the Advancement of Science, founded in 1831, depended heavily for its sustenance on scientific societies spawned from the network of provincial, rationalistic dissent. Reflecting its origins, it never met in London although in its infant days it was captured, and has since been controlled, by the central elite. To say this, however, is to progress ahead of the story and we must rather return to the later eighteenth century, when an Anglo-American network of provincial, rationalistic dissent was a significant element in the world of science and culture. The letters which follow indicate the modes, styles and concerns of that network as seen in the particular linkage from Manchester to Philadelphia.

The earliest surviving communication from this link in the network is a letter from Thomas Percival to Benjamin Franklin of 1771. Characteristically, Percival encloses an offprint of a scientific publication, seeks critical commentary and concludes by saying "My friend Dr Priestley flattered me last summer with the prospect of seeing you at Manchester, and obligingly promised to introduce me to your acquaintance." It is not known how Franklin responded or when the two eventually met. The sustaining network of shared friends, values and commitments however, was such as lead to a ripening correspondence. Two years later Franklin wrote with commentary on census attempts, and remarks on climate and health. The following year Percival in his turn acknowledged receipt of "a packet of papers on the American affairs."' He was quick to point out that he had "distributed the pamphlets amongst persons of the first consequence in this town and neighbourhood. They have already circulated through a considerable number of hands and cannot fail of making some useful impressions." Percival was equally quick to "inclose a little paper" of his own "extracted from a long memoir which I shall soon send to . . . the Royal Society". The easy turn from political affairs to scientific enquiry highlights how, for Franklin, Percival and other members of the network, similar values underlay the two pursuits.

By this time Thomas Henry and Benjamin Rush were also active within the Manchester–Philadelphia strand of the network. In 1774 Henry sent Rush his book on the properties of magnesia. Rush returned the favour, conveying the first volume of the *Transactions* of the American Philosophical Society and announcing that he had proposed Henry as a member of that fledgling body. The parallelism of developments in the two cities, and the way in which the network was underpinned by common concerns with trade and with medicine may be seen in Henry's response. After dilating on the "very pleasing proofs of the progress science is making on your side of the Atlantic," he continued that "happy as I am at Manchester in the society of several men of real genius, and most diligent investigators of nature, yet I must think that an inhabitant of Philadelphia has ample reason to congratulate himself on being situated in a city where the literati so much abound. One of your Society, Dr Williamson, was at Manchester in January and seems to be a man of very extensive knowledge." (Hugh Williamson was just that and, as befitted a Pennsylvania-born, but Edinburgh-trained, physician, he was later to be a founder of the New York Literary and Philosophical Society.) Henry went on to mention "Dr Franklin, who . . . will carry you all the philosophical news," a new publication of Dr Percival which "he purposes to send by the first opportunity to you and Dr Morgan" and "Dr Priestley (who) is proceeding in his experiments and intends in about two months to publish . . . (details of how) he procures air six times more salubrious than common air (that is, the landmark discovery of oxygen)." Finally, it was reported that—in accord with best network practice—"Dr Priestley has kindly put up my name at the Royal Society; he and some other of my friends had recommended me to Dr Franklin who had promised me all his interest".

This letter, which also contains the remarks about "the unhappy divisions that prevail between the mother country and her colonies" shows this one strand of the network at the height of its power, at the moment when war was about to disrupt its activities and transform its contexts. Even so, the next letter from Henry to Rush (dated May 10, 1784) remarks that "the progress of literature and philosophy have not been wholly interrupted. As a proof of this a Society for the promotion of these objects has been established in this place, and has obtained some degree of celebrity . . . You were once so obliging to offer to get me elected into your respectable Society; and with your permission I will propose your name to be enrolled among our Honorary Associates." Henry's letter was conveyed by "Mr Joseph Hadfield" (who) belongs to a respectable commercial house here . . . and is going to settle in America." Symbolically covering the distance between both Manchester and Philadelphia philosophers and the Royal Society of London, the letter also reports how "a most excellent mathematician and philosopher and a very worthy man from Manchester had been "black balled", Sir Joseph (Banks) making a party against him". In like manner, Percival wrote to Franklin how "the loss of Sir John Pringle has almost ruined the Royal Society. But you are no stranger, I presume, to the disgraceful contentions of that learned body, and to the conduct of the President." Once again distance from London was but the obverse of the coin of network linkages. Percival also wrote to Franklin saying the Manchester Society was publishing one of his scientific papers and that "I am commissioned to return the thanks of the Society to you for this communication; to request your future correspondence; and to acquaint you that we have honoured our institution by electing you an extraordinary member." Once more, the message was conveyed by a commercial traveller between the two cities. That same envoy also carried Rush's diploma and another letter containing news of Priestley's work and greetings to Mancunians settled in Philadelphia.

Not altogether surprisingly, the American Philosophical Society returned the honour done two of its members by Percival and Henry. The ties of sentiment and interest were further strengthened by the formal exchange of publications. As president of the Manchester Society Percival wrote to Franklin, President of the American Philosophical Society, acknowledging receipt of "the Vol. of American Phil. Transactions" and sending the "present of our Memoirs". His letter referred to a visit of Dr and Mrs Priestley—the doctor "at this time gallantly engaged in attempts to convert the Jews to Christianity"—and touched extensively on the need to find means to purify the air of manufacturing towns, seeking Franklin's advice. We cannot pursue the means by which two other members of the Manchester group were elected to the American Philosophical Society in 1789. Nor can we fully share the surprise with which Percival reported to Rush the following year that "The Academy of Arts and Sciences at Cambridge in New England have lately conferred on me the unsolicited honour of election into their very respectable Society." Nor is it possible to follow the sequence from the French Revolution to the War of 1812 which brought this particular Anglo-American link to an end. Instead, I shall point to two passages which so perfectly express the common hopes of the members of the Manchester–Philadelphia strand in the network of provincial dissent, that it seems appropriate to conclude by quoting them in full. In October 1786 Percival wrote to Franklin that:

> "The diffusion of the arts and sciences through so many extensive regions of the globe must afford a subject of contemplation peculiarly satisfactory to your mind . . . And I hope that Sun which has so long blessed the nations (namely, Franklin himself) will not set till the interests of truth and knowledge, of civil and religious liberty, are truly established in the Western Hemisphere, which it now enlightens".

In March 1790 he put it this way, to Benjamin Rush:

> "I honour your enterprising genius, which is continually exerting itself in some liberal scientific and public spirited undertaking. Mental energy seems now to be the characteristic of America; and great are the expectations which may reasonably be formed concerning your rising republic".

I thank the John Simon Guggenheim Memorial Foundation and the National Science Foundation for partial support of the research reported here. I am also indebted to the Trustees of the British Museum, to the Birmingham Public Library, to the Library of the American Philosophical Society and to the Historical Society of Pennsylvania for permission to quote from letters in their possession. Robert Bud, David Miller and other students and colleagues at the University of Pennsylvania provided thoughtful criticism and generous assistance.

The Viking Mission search for life on Mars

Harold P. Klein

Biospherics, Incorporated, Rockville, Maryland

On each of two unmanned Viking spacecraft, a number of investigations are planned to be conducted on the surface of Mars this summer. Included in the science payload are instruments designed to determine the state of chemical evolution, including the possible presence of living organisms, on that planet.

ON July 4, 1976, the first of a pair of unmanned spacecraft is scheduled to touch down on the planet Mars in an area located at 19.5°N and 34°W, in a region of low elevation, which seems to be a drainage basin for a large portion of the equatorial region of Mars (Fig. 1). Two months later, the second Viking spacecraft should touch down further north (44.3°N and 10°W) in another region of low elevation, relatively close to the edge of the northern winter ice cap, and at a latitude where maximum quantities of water vapour have been measured in the Martian atmosphere[1].

Aboard both of these landers will be identical science 'payloads', including cameras, meteorological and seismic stations, and analytical equipment to conduct analyses of the surface material. These investigations are now planned to be conducted over a period of two months on each lander, but it is possible that the experiments will continue over considerably extended periods of time—approaching a full Martian year—if further funding can be made available for an extended Viking mission. The scientific objectives of this mission are manifold, but, among these, an assessment of the organic evolutionary state of the planet including a search for extraterrestrial life, is of paramount importance. For the first time, another planet is to be probed directly for evidence supportive of modern ideas on the origin of life[2]. Mars, although not a hospitable planet as judged by terrestrial standards[3], is the one planet, other than Earth, that most nearly satisfies our theoretical presumptions of the conditions for life to have evolved[4].

For many years, telescopic evidence of morphological features, and their temporal changes, inspired speculative controversies about the presence of life on Mars. These older controversies no longer bear discussion in the light of the Mariner Mars-orbiter and fly-by missions (1964–71) which gave us a complete photographic mapping at resolutions of 1 km or better. It is now clear that water in a form available to living organisms is a likely limiting factor. The polar caps seems to contain substantial quantities of ice, but at temperatures far below those that would support any active terrestrial life. The temperate latitudes have congenial daytime temperatures, but humidities far below those known for any earthly desert. A number of mechanisms have, however, been proposed for possible local anomalies that could furnish moisture at temperatures consistent with metabolism[5]. In addition, the Mariner photographs show many surface features that are most easily explained by assuming that episodes of weather, precipitation and the carving of river valleys have occurred in the geological history of Mars.

These considerations have been taken into account, together with the engineering constraints, in planning the selection of landing sites. However, until our first successful landing, we have no reliable empirical basis for predictions about the local habitats of Mars. We have then been obliged

to try to outguess Nature over a range of possible realities in planning these experiments.

Scientific payloads of Viking mission

While all of the experiments are expected to contribute at least peripheral information pertaining to the local milieu of the landers (for example, local temperatures, wind speed and direction, atmospheric composition, elemental composition and magnetic properties of the surface material), three of the investigations hold the greatest promise for contributing directly to the question of organic chemical evolution on Mars.

The first of these is the imaging investigation, which will utilise two facsimile cameras, capable of stereoscopic imaging, on each lander. These cameras will scan the landing site area in black and white, colour and infrared, with a resolution of about 2 mm immediately below the landers. Examination of the surrounding terrain may reveal evidence of past or present living systems. Furthermore, frequent scans of this area may show signs (for example, colour changes) suggestive of living processes[6].

Also on board each Viking lander is an instrument that will perform organic analyses of the Martian surface material. This is essential not only for obtaining results which may be relevant to Martian life, but also may provide valuable information in assessing the state of molecular complexity if the planet is in a prebiotic state of evolution. The heart of this instrumentation is a mass spectrometer, chosen because of its high sensitivity, wide dynamic range, and broad applicability. For the analyses, samples will be heated in ovens at 200 °C and at 500 °C, and the evolved organic vapour (if any) will first pass through a chromatographic column for separation. A complete gas chromatogram takes 84 min and, during this period, the mass spectrometer will record a complete mass spectrum from mass 12 to mass 200 every 10.3 s (ref. 7).

The biological payload supports three separate experiments which are based on different assumptions about the nature of a possible Martian biology. In the face of our relative ignorance of the local environmental conditions on Mars—for example, up to the present, there is no positive indication that nitrogen is present on Mars[8]—there is ample reason to approach the question of life detection on Mars with a broad approach. The combination of biological experiments on Viking is thus designed to create a diverse set of environments within which to elicit evidence of metabolism. Three kinds of metabolic question will be asked. Is there evidence for building up of molecules containing carbon starting with ^{14}CO or $^{14}CO_2$? Can small radioactive organic molecules be broken down to $^{14}CO_2$? Are gases other than CO_2 produced or consumed? These broad experiments try to measure anabolic and catabolic reactions on Mars. The conditions vary from dry to wet; include the presence of simple and complex nutrient sources, as well as the absence of added nutrients; and include incubation in the light or dark.

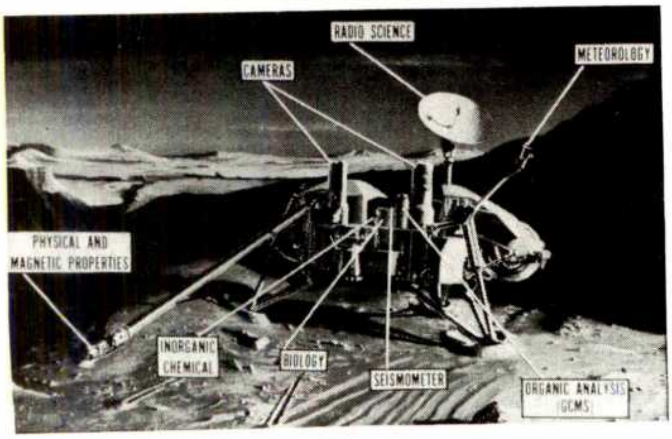
For the biological experiments samples will be analysed several times during each mission. They will be obtained from the upper 4 cm of surface material and will be incubated for different periods of time in each experiment. Incubation temperatures are expected to run at 15 ± 10 °C. Furthermore, each of the experiments is provided with the capability to perform a control experiment with samples preheated to 160 °C for 3 h, in the event that any of the experiments gives a presumptive positive result.

Surface samples (approximately 6 cm^3) will be delivered into the biology instrument by an extendable boom at the end of which a jaw-like scoop digs into the surface to acquire samples (Fig. 2).

The biology instrument contains four modules, one for each of the three experiments, as well as a common service module, which contains a helium source used to rotate incubation cells, purge incubation chambers, and for other operations as well as a system of vents for gases and for liquid wastes. A detailed description[9] of the instrument is beyond the scope of this communication, but a brief account follows.

The pyrolytic release (or carbon assimilation) experiment is designed to measure either photosynthetic or dark fixation of CO_2 or CO into organic compounds[10,11]. Both of these gases are known to be present in the atmosphere of Mars, and the experiment is designed to simulate, as closely as conditions permit, the actual Martian environment. The experiment hardware includes a xenon arc lamp with a spectral range and distribution quite similar to the solar spectrum, and with an intensity of about 20% of the maximum Martian solar irradiation at the surface. The light source is provided with a filter to remove ultraviolet radiation below 340 nm to prevent the non-biological fixation of carbon monoxide into organic compounds, as has been reported by Hubbard *et al.*[12,13]. For this experiment, 20 μCi of a mixture of $^{14}CO_2$ and ^{14}CO (in a ratio of approximately 95 : 5) is injected into the headspace (containing Mars atmosphere) above a 0.25-cm^3 surface sample that has been sealed off in one of the three incubation chambers provided. Incubation proceeds for the next five days in the light. While the incubation is proceeding, a long background count is taken. Following this period, the original incubation atmosphere is automatically vented, and the sample is pyrolysed by heating to 625 °C. During this stage of the experiment sequence, any residual initial radioactive CO or CO_2 will be driven out of the sample, through a column, the organic vapour trap (OVT), and into a ^{14}C detector, while organic fragments will be adsorbed on the OVT. After counting at this point in the sequence, the radioactive gases in the detector are automatically vented, and the detector is then heated to remove adsorbed gases. Following this step, and several additional helium purges of the OVT and the detector, the organic matter that had been trapped on the OVT is now eluted by heating it to 650 °C for 3 min. During this heating, any trapped organics are released from the column and are simultaneously oxidised to CO_2 by copper oxide present in the packing of the OVT. The effluent from this procedure is purged into the detector and counted. A radioactive peak at this time would constitute presumptive evidence for biological activity, to be followed by a control experiment using heat-sterilised soil.

Fig. 2 Viking lander. Surface sampler is seen extended at left. Biology sample processor and distribution assembly is seen midway between the two cameras. Biology instrument is beneath this component and not visible in this figure.



In addition to the sequence just described, the experiment can be modified by the introduction of water vapour into the incubation atmosphere by commands from Earth. Another commandable option in this experiment is to turn off the lamp to conduct a dark incubation.

The labelled release experiment[14] will test for metabolic activity during incubation of a surface sample that has been moistened with a solution of ^{14}C-labelled simple organic compounds, consisting of a mixture of one-, two-, and three-carbon compounds, all uniformly labelled and in dilute aqueous solution. For this experiment, one of the four incubation cells provided in this module will receive 0.5 cm^3 of surface material, and will be sealed with Martian atmosphere trapped in the headspace above the sample. Following this, a background count, lasting approximately 24 h, is taken, after which 0.115 cm^3 of nutrient is automatically injected onto the sample. Incubation proceeds for the ensuing 8 d. A second injection of labelled nutrient then occurs, and incubation continues for 2 d. During the entire time, the atmosphere above the sample is monitored by a ^{14}C detector to determine the kinetics of released labelled gas following each injection. Incubation is ended by a termination sequence to bring the background count down to pre-incubation levels. Following this 'clean-up' operation, the experiment is ready for another analysis cycle.

The gas exchange experiment[15] will be conducted in two different modes using the same equipment. In one mode (the 'humid' mode), Martian surface samples will be incubated in the presence of CO_2 and water vapour. This mode is based on the assumption that substrates may not be limiting on Mars, but that biological activity is dormant in these samples until enough water becomes available in the environment. The second mode (the 'heterotrophic' mode) assumes the presence of frankly heterotrophic organisms in the Martian surface.

For both of these experimental modes, it is further assumed that metabolism of active organisms in the samples will cause the disappearance or release of one or more gases known to be involved in terrestrial metabolic processes. For an analysis, 1 cm^3 of sample is delivered into the single incubation cell. A mixture of CO_2 and Kr (in He) is then added to serve as the incubation atmosphere. After this step, 0.5 cm^3 of nutrient is delivered to the bottom of the incubation cell. During incubation, the sample is retained in an inner-cup within the incubation cell so that the nutrient does not come into direct contact with the sample. The inner cup is porous and allows equilibration between the sample and the incubation atmosphere. Gas samples (100 ul) are taken from the headspace above the sample immediately after the nutrient has been injected and at specified times thereafter for the next 7 d. The gas samples are swept through a chromatographic column and the components detected by a thermal conductivity detector. If no command to the contrary is given after 7 d in the 'humid' mode, the instrument will automatically inject additional nutrient bringing the total aqueous volume now to 2.5 cm^3. With this amount of nutrient, the sample will be wet by the nutrient and incubation now will proceed in the 'heterotrophic' mode. (The nutrient solution contains both D- and L-amino acids as well as other organic substrates, growth factors and inorganic compounds.) Incubation continues in this mode with gas samplings at stipulated intervals for the next 9 d. At this point, options exist to proceed in various directions, depending on the data obtained. One is to drain the nutrient from the bottom of the cell and to introduce fresh atmosphere and fresh nutrient, and to incubate the original sample for an additional 19 d. Or, the initial incubation conditions can simply be extended for an additional 19-d period (that is, without draining the original nutrient or changing the gas atmosphere). If circumstances warrant it, the nutrient can be drained, the original sample dried, and a new sample introduced on top of the first one for a second analysis in the 'heterotrophic' mode.

In addition to the ^{14}C data from the two radioactivity detectors, and the gas chromatographic data, several other measurements will be telemetered periodically from the spacecraft during the course of these experiments. These include the status of the xenon lamp, the position of each incubation cell, temperature measurements of each incubation cell being used, and temperature measurements of both nuclear detectors, of the OVT and of the gas chromatographic column and detector. In addition, we will receive data on the pressure of the critical helium reservoir in the common services module.

Figure 3 shows one of the flight instruments in its final stages of assembly. It contains, in addition to the incubation cells and sample distribution system, four different gas supplies, two different nutrients, two ^{14}C detectors, a thermal conductivity detector and chromatographic system, 43 different heaters, 4 thermoelectric coolers, 39 miniature latching solenoid valves, a xenon arc lamp, 22,000 transitors, and 18,000 other electronic parts. All of this is packaged into a volume somewhat greater than 1 foot^3, and weighs 35 pounds.

The three biology experiments differ in their sensitivity, as measured by their responses to terrestrial organisms. Both the gas exchange and labelled release experiments have, by now, been tested against a wide variety of soils and they readily "detect" the presence of microbial flora in these samples when they are incubated in ambient terrestrial conditions. When these soil samples are incubated under the conditons in which the experiments will be operated on Mars, the responses are delayed by prolonged lag periods, but qualitatively similar responses are seen. In contrast, the pyrolytic release experiment does not respond to terrestrial soils at all when incubated in "Martian" conditions. Only when water is included in the incubation test cell is terrestrial biological activity demonstrable in this experiment. Accordingly, during the long test programme that preceded the manufacture of the flight instruments, several 'standard' soils were used to challenge the two 'wet' experiments. For the pyrolytic release experiment, soil was preincubated in the light in the presence of water to provide fixed radioactive carbon compounds, dried, and then used in this form to test the equipment. Since the final flight hardware is designed to work on Mars, and not on Earth, and because the design of the biology package precludes repetitive incubations (beyond four per experiment), and because of the rigid requirements to prevent terrestrial contamination, the flight instruments were not, and could not be, tested with terrestrial soils. Precursor instruments, built to flight specifications (with minor exceptions), did go through at least one prolonged test in simulated Martian conditions using one of our 'standard' soils, (containing 1×10^6 aerobic, and 5×10^4 anaerobic organisms per g; with a pH of 4.8 and an organic content of 0.8%). In addition, a flight-like instrument was installed on a lander and tested as part of a complete system, but these tests did not include analysis of any soils. Rather, known mixtures of gases were processed through the gas exchange hardware, and $^{14}CO_2$ was used to challenge the other two experiments. These tests[16], while not completely satisfying, in that only a part of the complete system was tested, gave results entirely consistent with extensive prior testing at the module level. Finally, at the component level (that is, detectors, chromatograph columns, and so on), many of the actual flight components were extensively tested for their scientific as well as their engineering characteristics. In these tests, no significant anomalies were uncovered. In summary, the testing programme was less than optimal, being limited by time and fiscal constraints, but met the minimum standards for confidence that the instruments will perform their nominal functions after landing on Mars.

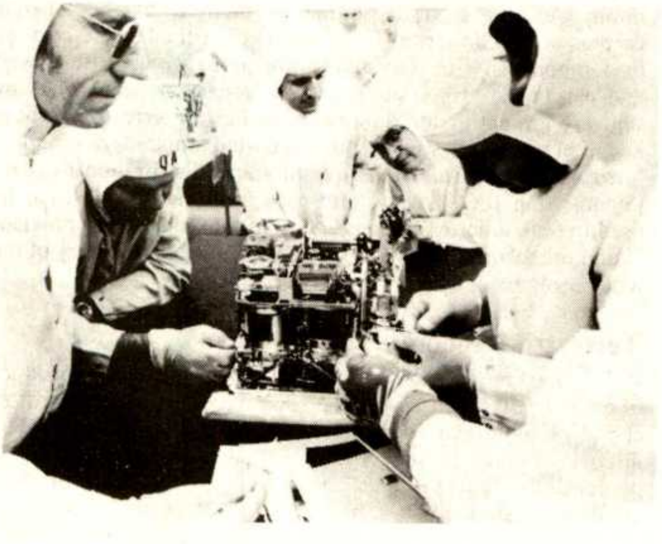


Fig. 3 Biology flight instrument in final stages of assembly.

The team of scientists selected by NASA, in 1969, to plan and conduct the biological investigation on the Viking spacecraft consisted of the authors and the late Dr Wolf Vishniac (University of Rochester, Rochester, New York). The following individuals are collaborators in these investigations: Bonnie Berdahl, Glenn Carle and Richard D. Johnson (NASA, Ames Research Center, Mountain View, California); George Hobby (California Institute of Technology, Pasadena, California); Jerry Hubbard (Georgia Institute of Technology, Atlanta, Georgia); and Patricia Straat (Biospherics, Incorporated, Rockville, Maryland).

Xenon record of the early Solar System

D. D. Sabu
Department of Chemistry, Grambling State University, Grambling, Louisiana 71245

O. K. Manuel
Department of Chemistry, University of Missouri, Rolla, Missouri 65401

We suggest that xenon isotopes in meteorites and in outer regions of the Sun contain debris from a supernova which exploded in the vicinity of the present Solar System, and we conclude that xenon in the outer planets is enriched in this supernova debris.

IN 1960 Reynolds[1] noted that the isotopic composition of xenon trapped in the Richardton olivine–bronzite chondrite and in the Murray carbonaceous chondrite differed in a uniform manner from that of xenon in air. He concluded that the general isotopic anomaly pattern of xenon in meteorites was primordial in origin, that is, characteristic of xenon incorporated in the meteorites at the time of their formation. Subsequent analyses confirmed that xenon trapped in other stone meteorites exhibits a similar pattern of isotopic anomalies[2–4], now commonly designated as AVCC xenon.

In 1964 Reynolds and Turner[5] analysed the isotopic composition of xenon released by stepwise heating of the Renazzo chondrite and observed an unusual isotopic anomaly pattern in the xenon released at 700–900 °C. Relative to the two more abundant, β-shielded isotopes, ^{128}Xe and ^{130}Xe, there was an enrichment of the heavy isotopes, $^{131-136}$Xe, of the general form expected for a fission spectrum. It was noted that ^{124}Xe and ^{126}Xe also seemed to be enriched in the xenon released at these temperatures, and small amounts of these isotopes would have to be explained by some additional process. During the next eight years, analyses in several laboratories of xenon released by stepwise heating of other carbonaceous chondrites confirmed the presence of this strange xenon component[6–12]. Attempts to understand the origin of this component were, however, focused exclusively on the enrichment of the heavy isotopes, and the strange xenon came to be referred to as "fission-produced xenon"[9], "Renazzo fission"[8] and "CCF" as an abbreviation for carbonaceous chondrite fission[13].

Possible explanation

In discussing the anomalous xenon in Renazzo, Reynolds and Turner[5] had stated that there were relatively large errors in the measurements of the light isotopes, but by 1972 relatively large enrichments of this anomalous xenon had been observed in other carbonaceous chondrites. It was then noted[14] that all available data on xenon released from carbonaceous near 800 °C showed an excess of the light, proton-rich isotopes in addition to the enrichment of heavy, neutron-rich isotopes. This observation could not be explained by any of the mechanisms previously proposed to account for the excess heavy xenon isotopes—spontaneous fission[5] of ^{244}Pu, a carrier[8] of heavy xenon adsorbed on carbonaceous material, neutron-induced fission[9], isotopic mass-fractionation[10,11], or fission[15–17] of superheavy elements. We therefore suggested that the anomalous xenon represents an isotopically distinct component which had been trapped in carbonaceous chondrites and suggested two possible mechanisms for its production before being incorporated into the meteorite; either by a mixture of severely mass fractionated xenon with excess $^{131-136}$Xe from neutron-induced fission of transbismuth nuclides, or by a supernova explosion generating an excess of the proton-rich isotopes via the p process and an excess of the neutron-rich isotopes via the r process. At that time we noted that there was, however, no evidence among the other elements for distinct isotopic components from separate nucleosynthesis events. But isotopically distinct components of oxygen[18] and magnesium[19] were found in carbonaceous chondrites within the next two years, and others[20–22] expanded on the possible role of a supernova explosion in producing the anomalous xenon in carbonaceous chondrites.

Since the term CCF xenon had connotations of a mechanism which could only account for part of the isotopic pattern of anomalous xenon released from carbonaceous chondrites near 800 °C, we suggested component X as a more innocuous term for the xenon component enriched in the light and heavy isotopes[14]. In 1974 we[23] reported that component X contained at least seven of the nine stable xenon isotopes and noted that AVCC xenon itself contained component X, that is, before the incorporation of xenon in stone meteorites there were sufficient quantities of component X to produce an observable alteration in the isotopic composition of xenon in the region of accretion.

Very recently Lewis *et al.*[24] reported the results of a beautiful detailed study on the abundance and isotopic composition of noble gases in separated mineral fractions of the Allende carbonaceous chondrite. Their results offer the best description of component X. In the following sections we will use these[24] and earlier results of studies on carbonaceous chondrites by stepwise gas extraction data from studies on terrestrial xenon, and the results of studies on solar-wind implanted xenon in lunar soil to determine the quantity and distribution of component X in the solar system. This information will then be used to seek a better understanding of the origin of component X and the record it contains of events in the early history of the Solar System.

Terrestrial xenon

It is now known that radiogenic ^{129}Xe, the decay product of extinct ^{129}I which Reynolds[25] discovered in the Richardton chondrite, is a common component of meteoritic xenon. The discovery of radiogenic ^{129}Xe in mantle-derived CO_2 (refs 26–28) demonstrates that the Earth started to retain this decay product at about the same time as the meteorites. Because of uncertainties in correcting for this radiogenic component, we will not

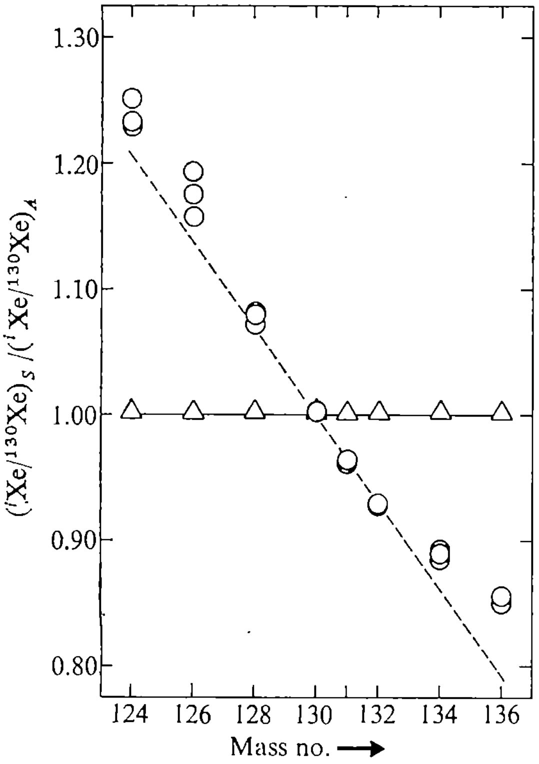

Fig. 1 A comparison of xenon isotope ratios in solar (S) and terrestrial xenon (A). The latter has been corrected for fission products from ^{244}Pu. Three separate estimates of solar xenon are in close agreement, and two of the estimates are coincident for xenon isotope ratios at masses 131 (refs 47, 48), 132 (refs 47, 48) and 136 (refs 43, 47).

consider the abundance of ^{129}Xe in comparing terrestrial and extraterrestrial xenon. Since excess $^{131-136}$Xe constitutes a major part of component X, however, it will be necessary to correct for fissiogenic $^{131-136}$Xe from another extinct radionuclide, ^{244}Pu. The latter was discovered in the Pasamonte achondrite by Rowe and Kuroda[29], and should have produced more than 15 times as much fissiogenic $^{131-136}$Xe as the spontaneous fission of ^{238}U over the history of the Earth.

The results of several analyses[30–32] of noble gases in shales and other carbonaceous minerals reveal extremely high concentrations of xenon, apparently from physical adsorption[33]. The suggestion that the atmosphere may contain only one-tenth[31] of the Earth's total inventory of xenon has been confirmed by analyses[28] of noble gases in a volcanic xenolith from the mantle. We will therefore consider the contribution from the fission of ^{244}Pu to the total concentrations of $^{131-136}$Xe in the 'crust–atmosphere' system, accepting the decay product of 17 Myr ^{129}I in the Earth's mantle[28] as evidence that ^{244}Pu in the mantle has made a negligible contribution to the isotopes, $^{131-136}$Xe, in this system. Since there are 8.2×10^{35} atoms of ^{136}Xe in the atmosphere[34], we estimate that the Earth contains a total of 8.2×10^{34} atoms of ^{136}Xe. Podosek[35] has shown that $^{244}\mathrm{Pu}/^{238}\mathrm{U} = 1.27 \times 10^{-2}$ when the St Severin meteorite started to retain ^{136}Xe from the decay of ^{244}Pu. Assuming that the Earth started retaining fissiogenic ^{136}Xe, ^{136f}Xe, at this time, an average uranium content of 1.3 p.p.m. for the Earth's crust[36], and a 6% fission yield at ^{136}Xe, then the decay parameters of ^{244}Pu (ref. 37) indicate that terrestrial xenon contains isotopes in the ratio $^{136f}\mathrm{Xe}/^{136}\mathrm{Xe} = 0.018$. From the fission yields of ^{244}Pu (ref. 38), and the isotopic composition of atmospheric xenon[39], we deduce the following isotopic composition of fission-free terrestrial xenon: $^{124}\mathrm{Xe}:{}^{126}\mathrm{Xe}:{}^{128}\mathrm{Xe}:{}^{130}\mathrm{Xe}:{}^{131}\mathrm{Xe}:{}^{132}\mathrm{Xe}:{}^{134}\mathrm{Xe}:{}^{136}\mathrm{Xe} = 2.353:2.206:47.03:\equiv 100:518.1:655.7:252.3:213.5$. We will use the symbol 'A' to designate fission-corrected atmospheric xenon of this composition in the following discussion on solar and meteoritic xenon. It should be stressed that we have purposely attempted to make a conservative estimate of the contribution of ^{244}Pu to $^{131-136}$Xe by selecting one of the higher estimates for the total xenon content of the Earth and by assuming that all of this xenon is in the 'crust–atmosphere' system. This was done so that we will not overestimate the amount of component X in other parts of the Solar System.

Solar xenon

Marti[40] first identified the presence of solar-wind implanted xenon in the Pesyanoe meteorite. Later studies of xenon in lunar fines and breccias confirmed the general isotope pattern which Marti reported in solar xenon. Several lunar scientists[41–44] interpreted the results of their xenon analyses as evidence that the isotopic compositions of atmospheric and solar xenon are related by mass fractionation and attempted to explain AVCC xenon as a mixture of solar xenon with CCF xenon. Although this interpretation of the three known reservoirs of xenon is not consistent with the experimental data[33,45], it was widely accepted as additional evidence for a large component of fission-produced xenon in carbonaceous chondrites.

Bogard *et al.*[46] and others[45] have noted that the 'true' isotopic composition of solar xenon is still not known because many variations observed in the isotopic composition of xenon in lunar soils arise from mass fractionation. To compare the isotopic composition of terrestrial and solar xenon, we have therefore selected similar estimates of the latter from analyses of xenon in lunar fines by three, well recognised laboratories: Pepin's laboratory at the University of Minnesota[43], Wasserburg's laboratory at the California Institute of Technology[47], and Geiss' laboratory at the University of Bern[48]. The authors identify this xenon as trapped lunar Xe (ref. 43), SUCOR Xe (ref. 47), and BEOC 12001 Xe (ref. 48). We normalise these xenon spectra to ^{130}Xe to facilitate identification of component X, which is enriched in both the light and the heavy isotopes relative to ^{130}Xe (refs 14 and 23).

The relationship between isotope ratios in solar xenon, $({}^{i}\mathrm{Xe}/^{130}\mathrm{Xe})_S$, and xenon isotope ratios in fission-free atmospheric xenon, $({}^{i}\mathrm{Xe}/^{130}\mathrm{Xe})_A$ is shown in Fig. 1. The dashed line corresponds to 3.45% per a.m.u. fractionation of the $({}^{i}\mathrm{Xe}/^{130}\mathrm{Xe})_A$ values. This fractionated terrestrial xenon is very similar to solar xenon at $^{128-132}$Xe, but the agreement is not very good at ^{124}Xe, ^{126}Xe, ^{134}Xe and ^{136}Xe. Since studies of xenon in carbonaceous chondrites show that component X is highly enriched in these four isotopes, we interpret Fig. 1 as evidence that solar-type xenon contains a larger fraction of component X than does terrestrial xenon. Deviations of the heavy isotopes from the fractionation line in Fig. 1 suggests that ~ 7% of ^{136}Xe in solar-wind xenon is from component X. This is a lower limit on the amount of component X in solar xenon; higher values would result if terrestrial xenon contains component X or a larger component of fissiogenic $^{131-136}$Xe than indicated by our purposely conservative estimate.

Meteoritic xenon

The isotopic compositions reported[24] for xenon in separated mineral fractions of Allende confirm the presence of an enrichment of both light and heavy xenon isotopes in component X. Figure 2 shows the correlation between the enrichment of the two lightest xenon isotopes and the heaviest xenon isotope in mineral separates of Allende[24] and in the gas released near 800 °C from earlier stepwise heating experiments on carbonaceous chondrites[5,8,10–12]. Our estimate of fission-free atmospheric xenon is also shown in Fig. 2, and changes in its composition which can be accounted for by mass fractionation are represented by dashed lines. We will discuss the intersections of the fractionation lines with the solid correlation lines later, after considering correlations of other constituents in the separated mineral fractions of Allende.

It has been suggested[24] that we were too hasty in concluding that the correlation shown in Fig. 2 is evidence that excesses of the light and heavy xenon isotopes were mixed before being

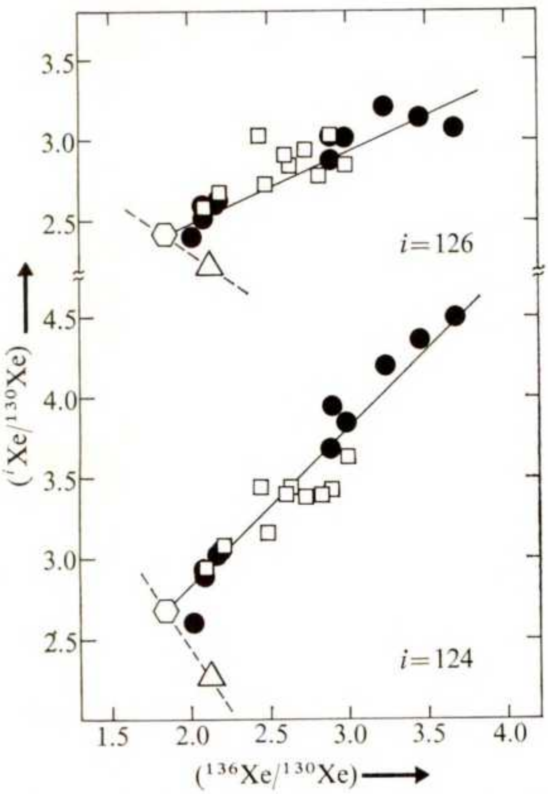

Fig. 2 The correlation of excess ^{124}Xe, ^{126}Xe and ^{136}Xe in mineral fractions of Allende[24] (●) and in xenon released by stepwise heating (☐) carbonaceous chondrites[5,8,10–12]. Isotope data from stepwise heating experiments are from a tabulation by Sabu *et al.*[23]. Fission of a volatile superheavy element cannot account for the correlations observed between light and heavy xenon isotopes.

trapped in meteorites. Anders *et al.*[49] suggest that the excess heavy xenon isotopes may be from *in situ* decay of a volatile superheavy element and the excess light xenon isotopes may be from an unknown isotopic fractionation mechanism which occurred during trapping. We will briefly examine the experimental evidence for this model.

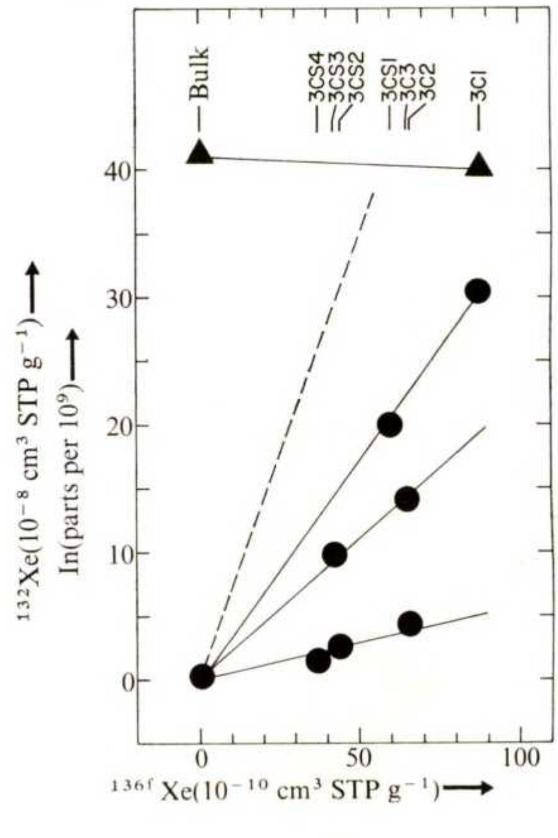
First, we will examine the correlations of excess ^{136}Xe with volatile elements in mineral fractions at Allende, since the previously reported correlation[16] of excess ^{136}Xe with ^{132}Xe, In and Hg in bulk meteorite samples seems to form the basis for this model. The correlations which result from the recent analyses[24,49] on In and Xe are shown in Fig. 3; Hg values were not reported. In 3Cl the concentrations of excess ^{136}Xe is enriched 180-fold over its concentration in bulk Allende, but In concentrations are unchanged. The dashed line in Fig. 3 shows the 45° correlation of excess ^{136}Xe with ^{132}Xe in average carbonaceous chondrites[16]. The xenon in separated mineral fractions of Allende seem to define three sets of correlations between excess ^{136}Xe and ^{132}Xe, none of which agrees with the correlation found in bulk carbonaceous chondrites. As we have noted earlier[50], the 45° correlation reported[16] between excess ^{136}Xe and ^{132}Xe in various meteorites occurs because the bulk isotopic composition of xenon in these meteorites is constant. Fractions of xenon enriched in component X can, however, be isolated by stepwise heating experiments or by separating mineral fractions. As the degree of separation of component X increases, the correlation with ^{132}Xe decreases. The correlation is best for bulk meteorite samples because AVCC xenon itself contains component X. But we find little, if any, evidence in Fig. 3 to support the previously reported correlation[16] of excess ^{136} Xe with In or ^{132}Xe.

To seek evidence that the excess light xenon isotopes in component X result from an unknown fractionation process, we next look for the effects of this process in the isotopes of krypton. The isotope ratios of krypton and xenon in the separated mineral fractions of Allende[24] are shown in Fig. 4. These isotope ratios show an excellent correlation between the enrichment of the light xenon isotopes and the heavy krypton isotopes. Anders *et al.*[49] suggest that the heavy krypton isotopes were enriched by fractionation, but we know of no fractionation process which could enrich the heavy isotopes of krypton and the light isotopes of xenon to produce the correlations shown in Fig. 4. We have not considered the light krypton isotopes because of hydrocarbon background and large uncertainties[24] but conclude from Fig. 4 that isotopic mass fractionation is not a viable mechanism to account for the excess light xenon isotopes in component X.

We will therefore consider the possibility that component X indeed represents an isotopically distinct component of xenon which has been trapped, together with terrestrial type xenon, in meteorites. Figure 5 compares the isotopic composition of xenon in the Earth, in average carbonaceous chondrites[4] and in the mineral fraction of Allende showing the most anomalous xenon, 3CS4 (ref. 24). The dashed line defines the values of $(^{i}\mathrm{Xe}/^{130}\mathrm{Xe})_{\mathrm{A}}$ with 2.25% per a.m.u. fractionation. This fractionation is also shown by the hexagons in Fig. 2 at the intersections of the dashed fractionation lines and the solid correlations. AVCC xenon, the xenon in separated mineral fractions of Allende, and the xenon released by stepwise heating of carbonaceous chondrites can be understood in terms of various mixtures of mass fractionated terrestrial xenon and component X. Deviations from the fractionation line at ^{136}Xe suggest that ~ 7% of the ^{136}Xe in AVCC xenon, and 50% of the ^{136}Xe in the 3CS4 fraction of Allende, are from component X. We regard these values as lower limits for reasons stated earlier.

Before considering the implications of component X, we wish to stress that results of the recent analyses on xenon in mineral separates of Allende[24] are inconsistent with our earlier suggestion[14] that the excess light isotopes in component X might result from mass fractionation. In addition to the reasons cited earlier for rejecting this mechanism, Lewis *et al.*[24] point

Fig. 3 Correlations of the 'fission' product, $^{136\mathrm{f}}$Xe, with In (▲) and ^{132}Xe (●) in mineral fractions of Allende[24,49]. The dashed line represents the correlation of $^{136\mathrm{f}}$Xe with ^{132}Xe in bulk meteorites if the amount of $^{136\mathrm{f}}$Xe is calculated in the same manner used to calculate $^{136\mathrm{f}}$Xe in Allende minerals[24].



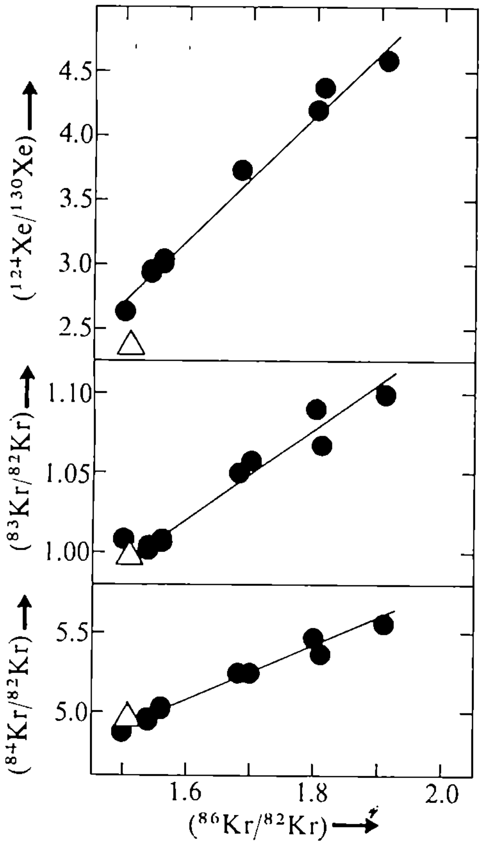
out that there is a definite excess of ^{124}Xe in the anomalous xenon above any plausible fractionation line through ^{126}Xe, ^{128}Xe and ^{130}Xe. This can be seen in Fig. 5 for the 3CS4 xenon. We therefore conclude that component X represents material from a supernova.

Implications of component X

We have shown that component X, an isotopically distinct type of xenon, is present in the Sun and in meteorites. The isotopic composition of xenon in the Earth, in meteorites and in the Sun can be understood in terms of mixtures of component X, fractionated terrestrial xenon, and radioactive decay processes. Terrestrial xenon seems to contain the least amount of component X, although recent analyses by Lightner and Marti[51] suggest that indigenous lunar xenon also contains little or no component X. We offer the following outline of a model to explain the abundance and distribution of component X, using the term Y when referring to the other xenon component.

Considering first the abundance of X and Y, it should be noted that both components made major contributions to xenon in our Solar System. The relatively small contribution of X to terrestrial and indigenous lunar xenon suggests that Y was dominant in the region where the inner planets accreted. Although X accounts for up to 50% of the ^{136}Xe in some mineral fractions of meteorites, such as the 3CS4 fraction from Allende, these minerals constitute such a small fraction of the total meteorite that they might be attributed to inclusions of small amounts of 'dust grains' which formed outside our Solar System. We have, however, shown that X is responsible for ~ 7% of the ^{136}Xe in both AVCC xenon and solar xenon. This observation requires relatively large amounts of X in the Solar System. In view of this, we regard the dominant role of X in certain meteorite minerals as evidence that X too was dominant in certain regions of our Solar System. We therefore conclude that the supernova was in the immediate vicinity of our Solar System.

Fig. 4 Correlations of excess heavy krypton isotopes with excess light xenon isotopes in mineral fractions of Allende[24] (●). The isotopic composition of atmospheric noble gases are represented by the open triangles (△).



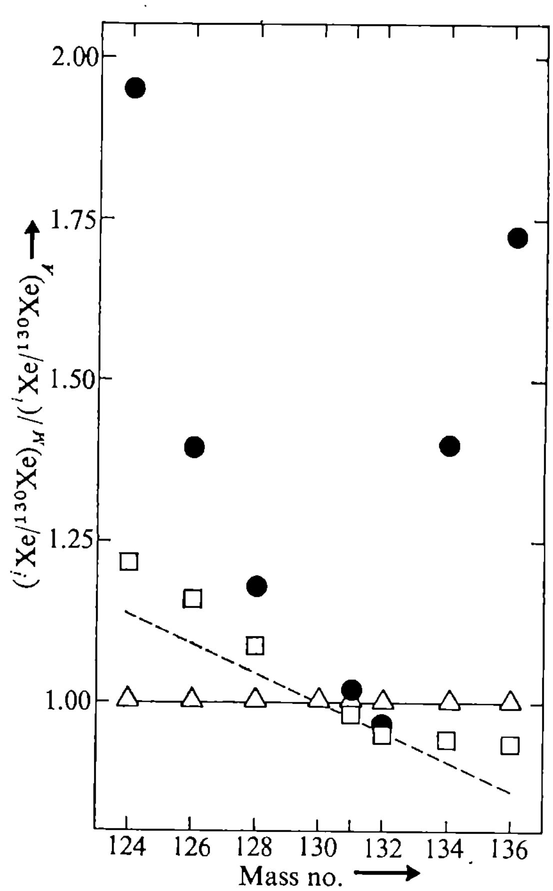


Fig. 5 A comparison of the xenon isotope ratios in AVCC[4] (□), in the 3CS4 fraction of Allende[24] (●) and in fission-free terrestrial xenon (△). Linear fraction of the latter, 2.5% per a.m.u., is represented by the dashed line. Deviations of meteorite xenon from this line arise from the presence of component X.

Considering next the distribution of X and Y, we suggest that these two isotopic components may correlate with other properties of our Solar System. As noted above, Y seems to have been dominant for the inner planets. In bulk meteorites X accounts for ~ 7% of the ^{136}Xe, but X is dominant in some meteorite minerals. The physical position of the parent meteorite material in the asteroid belt, and the occurrence of X-rich and Y-rich minerals in meteorites, suggests that this region may represent the boundary between regions where X and Y were dominant. There is an abrupt change in the character of planets in the region of the asteroid belt. The giant, less-dense planets lie beyond the asteroid belt and may contain relatively large contributions from X.

From the above considerations we conclude that our Sun was very likely once the smaller member of a binary star system. A supernova explosion of the other member produced debris rich in component X, in heavy krypton isotopes[24], in ^{244}Pu (ref. 52), ^{16}O (ref. 18) and ^{24}Mg (ref. 19), and perhaps rich in ^{26}Mg (ref. 19), helium and neon[24]. We expect that chemical elements of the outer planets will be enriched in these. Some of the debris also accumulated in the Sun, but the total solar abundance of X is not well defined, since material from the supernova may be enriched in the outer layers of the Sun. Hoyle[53] pointed out that initially low concentrations of helium, and high concentrations of metals in the iron group, in the Sun's core may account for the apparently low flux of solar neutrinos[54].

We thank Professor P. K. Kuroda for guidance in our graduate education.

Translation *in vitro* of vesicular stomatitis virus mRNA lacking 5′-terminal 7-methylguanosine

John K. Rose & Harvey F. Lodish

Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 01239

The 5′-terminus 7-methylguanosine of vesicular stomatitis virus mRNA is not essential for translation of the mRNA. The 7-methylguanosine seems to have a mediating rather than an obligatory role in ribosome binding by the mRNA and in mRNA translation.

MESSENGER RNAs (mRNAs) from several animal viruses and animal cells contain the 5′-terminal structure $m^7G^{5'}ppp^{5'}NmpN(m)p$[1–10]. Vesicular stomatitis virus (VSV) and reovirus mRNAs synthesised by virion polymerases in the absence of S-adenosyl methionine contain the respective 5′-termini $G^{5'}ppp^{5'}ApAp$ and ppGp; these RNAs will not direct synthesis of virus proteins in cell-free extracts from wheat embryo unless the methylated 5′-terminus $m^7G^{5'}ppp^{5'}N(m)pNp$ has been formed[11,20]. Also, unmethylated reovirus mRNA will not bind to wheat germ ribosomes[12]. In the light of these experiments and others involving the chemical removal of the terminal 7-methylguanosine from globin mRNA[13], it has been suggested that the 7-methylguanosine is obligatory for translation of all mRNAs in eukaryotic cells[11–13].

We were led to question the requirement for 7-methylguanosine in translation by the finding that the 5′-terminus of poliovirus mRNA purified from the polyribosomes of infected HeLa cells has the 5′-terminus pUp[14]. We present here results which show, in contrast to previous work[11], that a terminal 7-methylguanosine is not obligatory for translation of VSV mRNAs. Oxidation or removal of the 7-methylguanosine reduces the rate of protein synthesis about threefold and has a similar effect on the rate of mRNA binding to ribosomes in a reticulocyte cell-free system. Furthermore, some of this inhibition may be due to non-specific effects of periodate oxidation.

Removal of 7-methylguanosine

Cells infected with VSV contain five monocistronic viral mRNAs which encode the five viral proteins[15–17], and these mRNAs are complementary to the single-stranded RNA genome of the virus[18]. VSV mRNAs purified from the polyribosomes of infected baby hamster kidney cells all possess a common 5′-terminal tetranucleotide structure, $m^7G^{5'}ppp^{5'}mAmpmAmpCp$. This has only partial base methylation of the first adenosine and partial base and ribose methylation of the second adenosine[5]. The 5′-terminal 7-methylguanosine, because it has free 2′,3′ (ribose) hydroxyl groups, is susceptible to oxidation with periodate, yielding a 2′,3′-dialdehyde. Further treatment with aniline results in loss of the 7-methylguanosine by β-elimination. We found that the procedure which previously gave quantitative removal of this nucleoside from the terminal tetranucleotide[5] was unsuitable for use on whole mRNA because it caused extensive degradation and aggregation of the mRNAs as well as some uncharacterised modifications of internal nucleotides. Therefore, we used the procedure detailed in Fig. 1 which involves use of less periodate and removal of periodate from the initial reaction by successive ethanol precipitations of the RNA before treatment with aniline. This procedure minimised but did not eliminate degradation, as is shown by polyacrylamide gel electrophoresis of the denatured mRNA (Fig. 1). The viral protein(s) encoded by the mRNA in each band have been described previously[16] and are indicated in the legend to Fig. 1. Both periodate oxidation and β-elimination resulted in detectable levels of degradation which are most obvious in the decreases in the peak heights of the larger RNA species. It is difficult to quantify the exact amount of degradation of each RNA species because of the presence of multiple RNA species on the gel; however, the results suggest a loss of about 50% of N protein

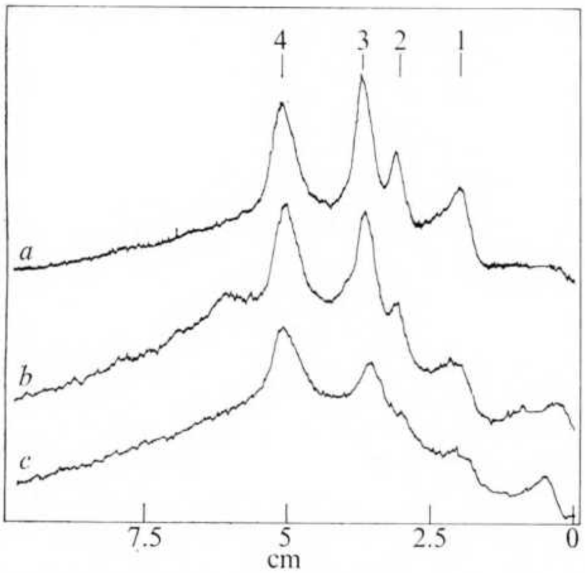

Fig. 1 Polyacrylamide gel electrophoresis of oxidised and β-eliminated VSV mRNAs. ^{32}P-labelled VSV mRNA was isolated by the following modification of a previous procedure[15]. A sample (2 l) of BHK-21 cells in spinner culture at 4×10^5 cells per ml were concentrated by centrifugation, washed twice with 100 ml of PO_4-free medium and then resuspended in 400 ml of PO_4-free medium. Actinomycin D (final concentration 5 µg ml^{-1}) and VSV (multiplicity of injection, 10) were then added, and incubation at 37 °C continued. One hour after addition of virus, 20 mCi of carrier-free $^{32}PO_4$ (New England Nuclear) was added, and incubation continued for 3 h. Infected cells were then isolated by centrifugation and resuspended in 10 ml of a solution containing 0.01 M $MgCl_2$, 0.01 M Tris–HCl (*p*H 7.4) and 25 µg ml^{-1} DNase I (Worthington, DPFF). Cells were lysed by addition of 0.1% sodium dodecyl sulphate (SDS) and incubated at 37 °C for 5 min. Then the extract lost detectable viscosity, and SDS and sodium acetate (*p*H 5 2) were added to final concentrations of 1% and 0.2 M, respectively, followed by extraction with an equal volume of a solution containing equal volumes of redistilled phenol and chloroform. After centrifugation, the aqueous layer was withdrawn and the phenol layer was re-extracted with 5 ml of 0.2 M sodium acetate (*p*H 5.2). The combined aqueous layers were then precipitated with 2 volumes of ethanol, followed by isolation of VSV mRNA by binding to and elution from 0.3 g of oligo(dT)-cellulose[15]. This procedure yielded from 3×10^8 to 10^9 c.p.m. in approximately 300 µg of mRNA. For periodate oxidation, 300 µg of lyophilised VSV mRNA (or 100 µg of VSV mRNA combined with 200 µg of unlabelled f2 phage RNA) was resuspended in 0.2 ml of 10 mM $NaIO_4$ (freshly dissolved) and incubated for 1 h at 23 °C in darkness. The RNA was then precipitated three times by addition of 0.4 ml of 0.1 M sodium acetate (*p*H 5.2) and 0.8 ml of ethanol. Half of the oxidised RNA was then resuspended in 0.1 ml of a solution containing equal volumes of 0.33 M aniline (*p*H 4.5, twice vacuum redistilled) and 0.15 M sodium acetate (*p*H 4.5) followed by incubation at 23 °C for 4 h. The RNA was then precipitated with ethanol three times as above.. Samples (approximately 10^5 c.p.m. each) of untreated (*a*), periodate-oxidised (*b*), and periodate-oxidised, β-eliminated RNA (*c*) were then denatured and subjected to electrophoresis on a 3.75% polyacrylamide slab gel containing 98% formamide, as described previously[15]. Microdensitometer scans of the autoradiogram of the wet gel are shown. Band 2 mRNA encodes the VSV G protein; band 3 encodes the N protein; and band 4 encodes the M and NS proteins[16].

mRNA (band 3) and 30% of M and NS mRNAs (band 4).

To quantify the removal of 7-methylguanosine from the mRNAs, samples were digested with penicillium nuclease (P1), an enzyme which degrades RNA to 5′ mononucleotides regardless of base or ribose modifications[19]. The 5′-terminal structures expected from P1 digestion of untreated and *β*-eliminated VSV mRNAs are $m^7G^{5'}ppp^{5'}(m)Am$ and ppp(m)Am, respectively[5]. To separate these termini from the 5′ mononucleotides, we subjected the digests to ionophoresis on DEAE paper at *p*H 3.5 (Fig. 2). Periodate oxidation and *β*-elimination resulted in the disappearance of radioactivity in $m^7G^{5'}ppp^{5'}(m)Am$ and its appearance in ppp(m)Am (lanes 1 and 2); the latter migrates much more slowly than the parent structure because of the loss of the positive charge on 7-methylguanosine and the gain of an additional negative charge from the unesterified phosphate. The structures of these nucleotides were demonstrated by their respective resistance and sensitivity to digestion with alkaline phosphatase digestion and by the identification of the products derived by venom phosphodiesterase digestion of each, as was done previously: $m^7G^{5'}ppp^{5'}(m)Am \xrightarrow{\text{venom}}$ pm^7G, Pi, p(m)Am; ppp(m)Am $\xrightarrow{\text{venom}}$ PPi, p(m)Am (ref. 5). The low levels of pppA and pppG in the mRNA preparations are derived from a fraction of the non-polysomal VSV RNAs which terminate in 5′ triphosphates[5].

No residual 5′-termini containing 7-methylguanosine were detected from *β*-eliminated mRNA (Table 1) since all residual radioactivity migrating at the position of $m^7G^{5'}ppp^{5'}(m)Am$ was sensitive to alkaline phosphatase. If 1% of the RNAs had contained the 5′-terminus $m^7G^{5'}ppp^{5'}(m)Am$), we would have detected it. Figure 2, lane 3, and Table 1 show that incubation of the *β*-eliminated RNA in the reticulocyte cell-free system in the conditions of protein synthesis does not result in the addition of 7-methylguanosine to the 5′ end; the end remains ppp(m)Am.

Translation without 7-methylguanosine

The products of translation of these mRNAs in the reticulocyte cell-free system were resolved by polyacrylamide

Fig. 2 DEAE paper iontophoresis at *p*H 3.5 of nuclease P1 digests of VSV mRNA. Samples containing 10 µg of RNA were incubated with 0.01 µg of P1 nuclease (Yamasa Shoyu Co., Tokyo) in 5 µl of 0.01 M MES (2-N morpholino-ethanesulphonic acid, *p*H 6.2) for 30 min at 37 °C. The limit digests of VSV mRNA were spotted on a sheet of Whatman DEAE (DE-81, 30×60 cm) paper and subjected to electrophoresis at 30 V cm^{-1} for 4 h in 5% acetic acid, 0.5% pyridine. Lane 1, untreated mRNA; lane 2, periodate-oxidised, β-eliminated mRNA; lane 3, periodate-oxidised, β-eliminated VSV mRNA purified after incubation in the reticulocyte cell-free system as described in Fig. 3.

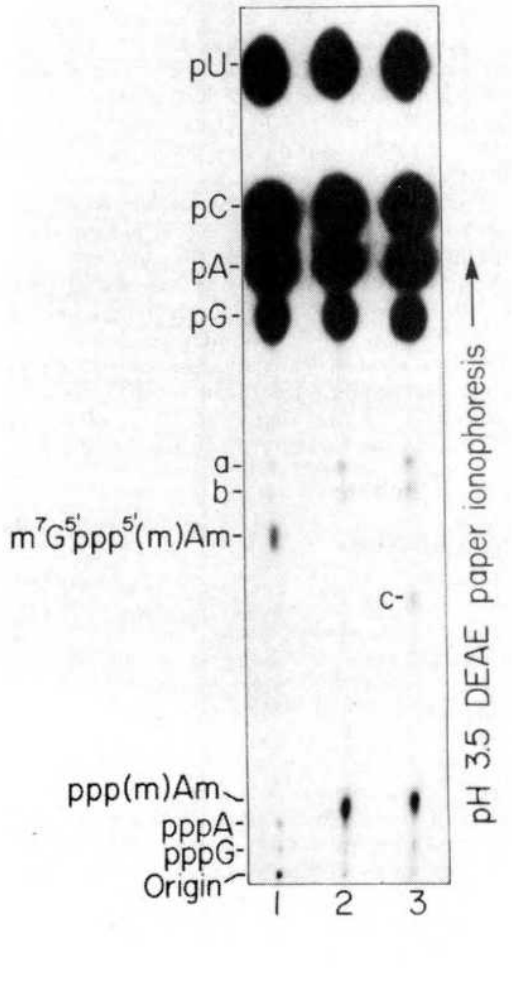

Table 1 Quantitification of 5′ termini

	% Total c.p.m. in each structure				
	${}_{\mathrm{HO}}{}^{\mathrm{m^7G5'ppp5'(m)Am}}{}_{\mathrm{OH}}$*	${}^{\mathrm{ppp(m)Am}}{}_{\mathrm{OH}}$	${}^{\mathrm{pppA}}{}_{\mathrm{OH}}$	${}^{\mathrm{pppG}}{}_{\mathrm{OH}}$	Total radioactivity (c.p.m.)
Untreated	0.17 (2141)	0.0006 (8)	0.019 (246)	0.018 (227)	1.26×10^6
Periodate-oxidised, β-eliminated	<0.0017 (<20)	0.17 (1874)	0.021 (241)	0.019 (208)	1.11×10^6
β-Eliminated (analysis after incubation in a protein synthesis reaction)	<0.0017 (<20)	0.16 (1788)	0.018 (212)	0.019 (210)	1.13×10^6

The 5′-terminal structures and 5′ monophosphates, separated as shown in Fig. 1, were cut out of the DEAE paper and radioactivity was determined in a scintillation spectrometer. For each structure c.p.m. are given in parentheses. Radioactivity in the spots labelled *a* and *b* (Fig. 2, lanes 1 and 2) was converted to P_i after alkaline phosphatase treatment and thus is either derived from modified nucleotides at internal positions in VSV mRNA or generated as an artefact of nuclease P1 digestion. The spot labelled (*c*) (Fig. 2, lane 3) appeared only in nuclease P1 digests of VSV mRNA which had been incubated in the reticulocyte cell-free system. Since half of the radioactivity in this compound was released as P_i after alkaline phosphatase digestion, it is presumably a P1-resistant modified dinucleotide of the form pNpN.

* We corrected for background due to trailing of mononucleotides into the region containing $m^7G^{5'}ppp^{5'}(m)Am$ as follows. Radioactivity in this region was eluted with 30% triethylammonium bicarbonate (*p*H 7.8), lyophilised, treated with alkaline phosphatase, and subjected to electrophoresis at *p*H 3.5 on Whatman No. 3MM paper, as described previously[5]. The radioactivity in ${}^{32}P_i$ relative to that in the phosphatase-insensitive structure $m^7G^{5'}ppp^{5'}(m)Am$ (16%) was taken as the fraction of contamination with mononucleotides, and the numbers in the table have been corrected for this contamination. All radioactivity in the region of $m^7G^{5'}ppp^{5'}(m)Am$ from β-eliminated RNA (285 and 260 c.p.m.) migrated as ${}^{32}P_i$ after phosphatase treatment, and the numbers given in the table have been corrected to the limits of detection of remaining $m^7G^{5'}ppp^{5'}(m)Am$.

gel electrophoresis. Figure 3*a* and *b* shows that synthesis of M, NS and N proteins is proportional to the concentration of added control RNA. Synthesis of the VSV G protein is presumably obscured by the large background peak of reticulocyte protein at 2 cm (compare Fig. 3*e*). Both periodate-treated and periodate-treated, β-eliminated mRNA direct the synthesis of authentic VSV M, NS and N proteins (Fig. 3*c* and *d*). Quantitation of these microdensitometer scans showed that periodate-treated RNA and periodate-treated, β-eliminated RNA directed the synthesis of 33% and 25%, respectively, of the amount of each of these proteins compared with the same amount of control RNA. The amount of protein synthesis directed by periodate-treated and periodate-treated, β-eliminated RNA was also directly proportional to added RNA concentrations (data not shown.

Because we were concerned that the reduced translation of the chemically treated VSV mRNA might in part be due to effects generated not by removal of the 7-methylguanosine but by internal oxidations of bases in the RNA as well as degradation, we performed control experiments on f2 phage RNA which had been mixed with the ^{32}P-labelled VSV mRNAs during the periodate-oxidation and β-elimination procedures. When translated in an *E. coli* cell-free system, periodate-oxidised, β-eliminated f2 RNA synthesised 80% of the amount of f2 coat protein (molecular weight 14,000) and only 50% the amount of RNA synthetase (molecular weight 50,000) as did untreated f2 RNA (data not shown). These experiments, as well as those showing degradation of VSV mRNAs described above, indicate that the level of translation in reticulocyte extracts after the periodate-aniline treatment must be regarded as a minimal estimate of the ability of VSV mRNA lacking 7-methylguanosine to function in protein synthesis.

Ribosome attachment

Two additional studies confirmed that VSV mRNA lacking 7-methylguanosine can participate in protein synthesis. After incubation in a reticulocyte extract in conditions of protein synthesis, 51% of control RNA is incorporated into polyribosomes; these contain, on average, 3.4 ribosomes per mRNA (Fig. 4*a*, Table 2). The same amount of periodate-treated, and slightly less periodate-treated, β-eliminated RNA is incorporated into polysomes. The decrease in the fraction of β-eliminated mRNA bound is due presumably to partial degradation of the RNA (Fig. 1). The average size of polysomes formed is reduced less than twofold compared with those from control RNA (Fig. 4*b* and *c*, Table 2). Assuming that the rate of polypeptide chain elongation and termination is the same for control and treated RNA, and that the average size of the VSV proteins produced is the same (compare Fig. 3), this experiment suggests that the rate of ribosome attachment to mRNAs lacking 7-methylguanosine is reduced less than twofold.

This conclusion is substantiated by the experiments in Figs 5 and 6 which measure directly the rate and extent of incorporation of mRNA into 80S initiation complexes. Incubation of control VSV mRNAs with reticulocyte extracts in the presence of anisomycin (1 mg ml^{-1}), a specific inhibitor of polypeptide chain elongation[25] results in incorporation of 54% of the RNA into an 80S complex (Fig. 5*a*). This complex remains stable in a solution of 0.5 M NaCl and 0.03 M magnesium acetate, but no initiation complexes are produced if the incubation mixture is of this ionic composition (data not shown). Hence, the rate of formation of an 80S complex can be determined accurately by diluting the incubation mixture into a solution of 0.5 M NaCl and 0.03 M magnesium acetate, followed by zone centrifugation to isolate the 80S complex. Figure 5 shows that 53% of periodate-treated RNA and 37% of periodate-treated, β-eliminated RNA is incorporated into a salt-stable initiation complex. Again, the reduction in the extent of binding is due, presumably, to degradation of RNA. The time required for half-maximum binding of control RNA to ribosomes is 12 s, while that for either periodate-treated RNA or periodate-treated β-eliminated RNA is about 35 s (Fig. 6). A threefold reduction in the rate of binding to ribosomes was also observed when untreated and periodate-treated, β-eliminated forms of a single VSV mRNA, that encoding N protein, were compared (control RNA, $t_{1/2}$=10.1 s; periodate-treated, β-eliminated RNA, 35.8 s; data not shown). This experiment rules out the possibility that the apparent reduction is due to preferential destruction of the larger VSV mRNAs by the chemical treatment.

The experiments reported here demonstrate that animal cell ribosomes can recognise the correct translation initiation sites on animal virus mRNAs from which the 5′-terminal 7-methylguanosine has been removed since such mRNAs direct the synthesis of authentic viral proteins. The changes which we observe in the ribosome binding of periodate-treated, and periodate-treated, β-eliminated mRNA are a threefold reduction in the rate of binding to ribosomes, a twofold reduction in average polysome size, and a 20–30% reduction in the total amount bound. The effect of the chemical treatments on the total amount of mRNA binding may be due only to mRNA degradation. Furthermore, we cannot rule out the possibility that the effect on the rate of binding may be due not to the removal of 7-methylguanosine but to nonspecific modifications introduced during periodate oxidation. Indeed, we have observed here that periodate oxidation on its own, which presumably leaves a dialdehyde

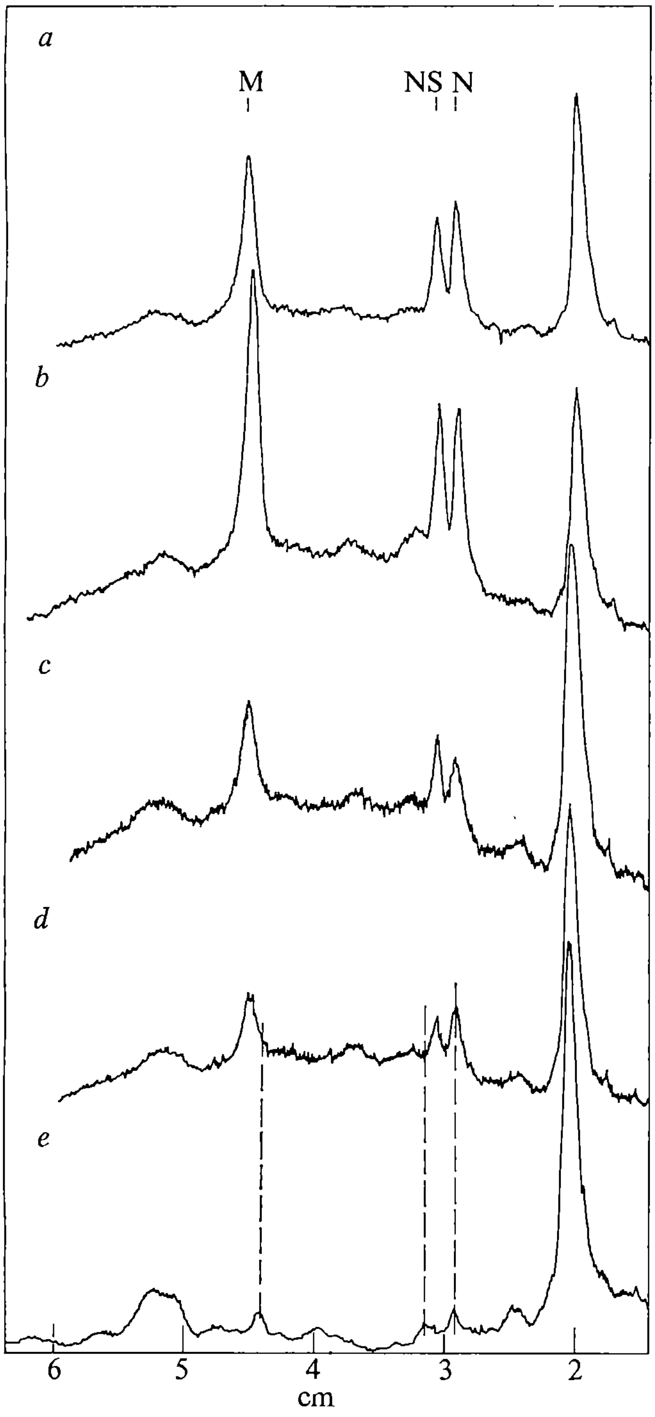

Fig. 3 Translation of VSV mRNAs Conditions for protein synthesis in cell-free extracts of rabbit reticulocytes have been described in detail[23]. Reactions (39 μl) containing 7 μCi ^{35}S-methionine (200,000 mCi mmol^{-1}, New England Nuclear), 10^{-4} M each of 19 non-radioactive amino acids, and the indicated amounts of ^{32}P-labelled VSV mRNA. S-Ado-Hcy (S-adenosylhomocysteine) was added to all reactions at a final concentration of 7.4×10^{-4} M to inhibit methylation. Incubation was at 30 °C for 60 min Pancreatic RNase (5 μg) was added, and incubation was continued for 5 min more. A sample (3 μl) of the reaction was analysed on a 13% polyacrylamide slab gel as detailed by Laemmli[24] Shown are scans of autoradiographs (10-d exposure) of the fixed, dried gel. The region of the gel containing the globin 7–9 cm) is not shown. *a*, 0.3 μg of control VSV mRNA (7.7 μg ml^{-1}), *b*, 0.6 μg of control VSV mRNA (15.4 μg ml^{-1}); *c*, 0.6 μg of periodate-treated VSV mRNA (15.4 μg ml^{-1}); *d*, 0.6 μg of periodate-treated and β-eliminated VSV mRNA (15.4 μg ml^{-1}), *e*, no added RNA.

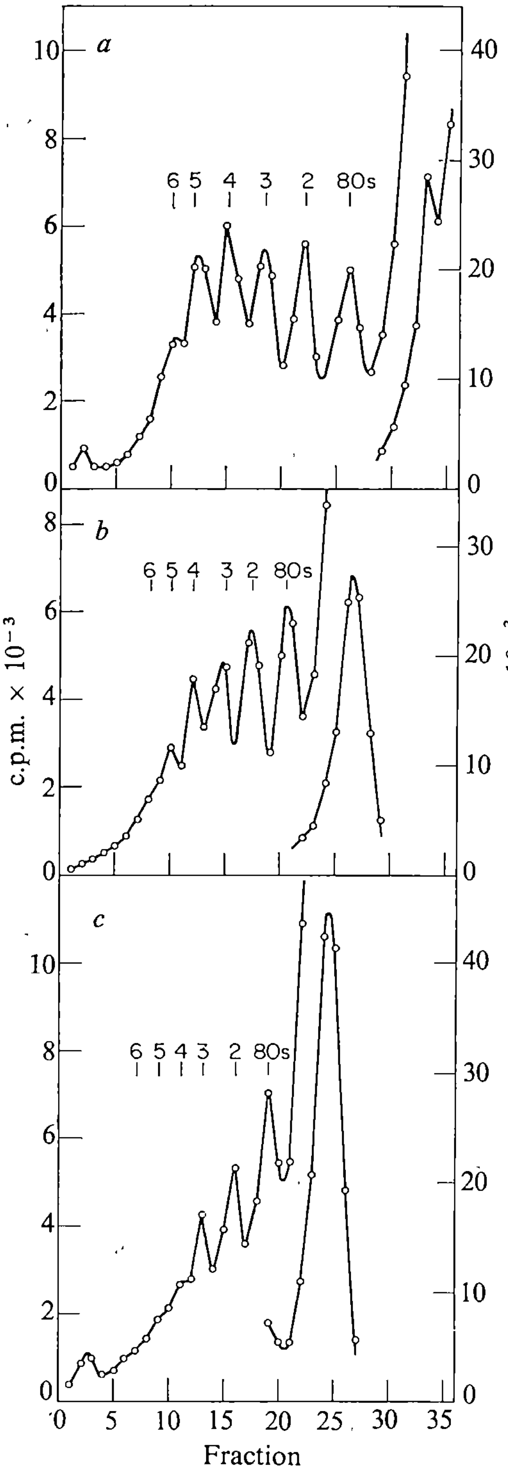

Fig. 4 Incorporation of labelled VSV mRNA into polysomes. Reticulocyte cell-free reactions (120 μl) contained 10^{-4} M each of 20 amino acids, 7×10^{-4} M S-Ado-Hcy, and 1.5×10^{5} c.p.m. (0.1 μg) of ^{32}P-labelled control VSV mRNA (*a*); periodate-treated RNA (*b*); or periodate-treated, β-eliminated RNA (*c*). Incubation was at 30 °C for 5 min. Reaction tubes were chilled on ice, and 1.2 ml of HSB (0.5 M NaCl, 0.03 M Mg (acetate)$_2$, 0.02 M HEPES, *p*H 7.5) was added. The samples were layered on a 36-ml 15–30% (w/v) linear sucrose gradient, made up in HSB, and centrifuged in a Beckman SW27 rotor at 4 °C at 26,500 r.p.m. for 4 h. Samples were collected through a flow cell in a Gilford recording spectrophotometer directly into scintillation vials. The arrows represent optical density peaks of the reticulocyte polysomes which are due, predominantly, to the endogenous globin mRNA. Each sample was bleached with alkaline hydrogen peroxide and counted using Aquasol (New England Nuclear) in a Beckman scintillation spectrometer. In control reactions (which were not incubated at 30 °C) only 2.3% of the radioactivity was found in the monosome or polysome regions of the gradient (data not shown). Analyses of data from this experiment are in Table 2.

Table 2 Incorporation of ^{32}P-labelled VSV mRNA into polysomes

	Control RNA	Periodate-treated RNA	Periodate-treated, β-eliminated RNA
c.p.m. in monosomes or polysomes $C = \sum_{i=1}^{7} C_i$	77,910	57,612	46,346
Proportionate number of ribosomes bound to VSV mRNA $R = \sum_{i=1}^{7} i\,C_i$	260,720	162,913	105,769
Ribosomes per bound mRNA $r = C/R$	3.35	2.83	2.28
Total c.p.m. recovered from gradient C_t	152,764	115,220	118,840
Fraction of mRNA bound to ribosomes $C_B = C/C_t$	0.51	0.50	0.39

In calculating the data given in line 2, the amount of radioactivity in any region of a polysome gradient was multiplied by the number of ribosomes per polysome (i), that is, by the number of ribosomes translating each mRNA in that peak. Hence, the total number of ribosomes translating the mRNAs is proportional to the sum of this product over all regions of the polysome gradient (line 2). Since the total radioactivity in polysomes (line 1) is proportional to the number of VSV mRNAs being translated, the average number of ribosomes per bound mRNA is given by line 3.

on the 7-methylguanosine as well as on the 3′-terminal adenosine of the mRNA, has virtually the same effect on reducing the rate of mRNA binding to ribosomes as does periodate-oxidation followed by β-elimination, which removes the oxidised nucleosides from the mRNA.

Conflicting data

Our conclusions conflict with those drawn in previous studies on translation of methylated and unmethylated VSV mRNAs synthesised *in vitro* by the virion-bound VSV polymerase. It was reported that VSV mRNAs synthesised *in vitro* terminate in $G^{5'}ppp^{5'}Ap$[20] and that translation of this RNA in the wheat embryo system will not occur unless methylation at the N^7-position of the guanosine has occurred before translation[11].

Attempting to reconcile these results with our own, we synthesised VSV RNA *in vitro* in the presence of S-adenosyl homocysteine and verified that the product RNA contains the 5′-terminus $G^{5'}ppp^{5'}Ap$. We found, however, that this product RNA does not contain any discrete VSV mRNA species comigrating with authentic VSV mRNA on formamide–polyacrylamide gels. Instead, 80% of the product RNA is larger than the N protein mRNA and heterogeneous in molecular weight, while the remaining 20% is present as bands running just faster than (approximately 100–200 nucleotides shorter than) the authentic VSV mRNAs (unpublished observations of M. Brock and J. Rose). In contrast, 80–90% of the *in vitro* product synthesised in the presence of S-adenosyl methiodine does comigrate with authentic VSV mRNAs. These results suggest that methylation is involved in synthesis or processing of VSV mRNAs into the correct poly(A)-containing mRNA species. The ability of these RNAs to function in *in vitro* protein synthesis is under study.

Extensive experiments carried out with reovirus mRNAs have also indicated a requirement for a 5′-terminal 7-methylguanosine in translation and ribosome binding[12]. If the methylated and unmethylated mRNAs compared in these experiments differ in no way other than the presence

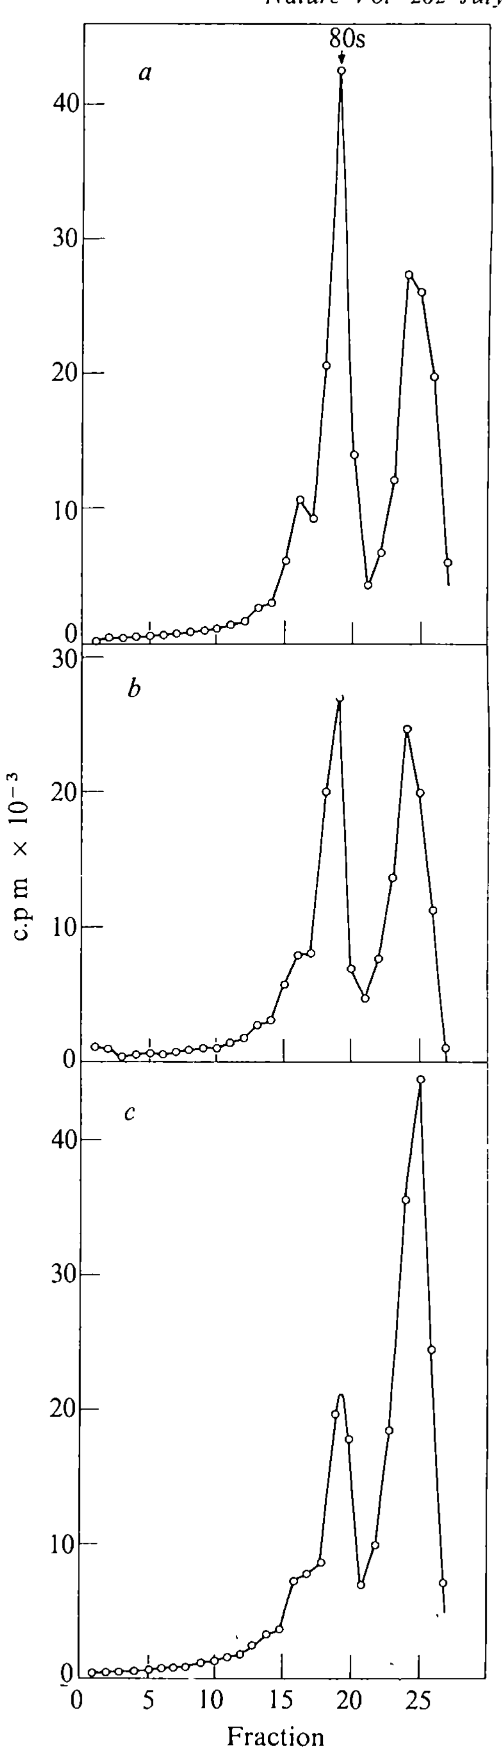

Fig. 5 Binding of ^{32}P-labelled VSV mRNAs to reticulocyte ribosomes. Reactions contained anisomycin (1 mg ml^{-1}), a specific inhibitor of polypeptide chain elongation[25] but were otherwise identical to those of Fig. 4. Gradient centrifugation and counting of the samples was as in Fig. 4. In reactions not incubated at 30 °C, 2.1–2.6% of the ^{32}P-labelled RNA was found to sediment faster than 40S (data not shown). The percentage of added ^{32}P-labelled mRNA bound to ribosomes after incubation was 54% (*a*); 53% (*b*), 37% (*c*). The concentration of VSV mRNA in each reaction was 1 μg ml^{-1}.

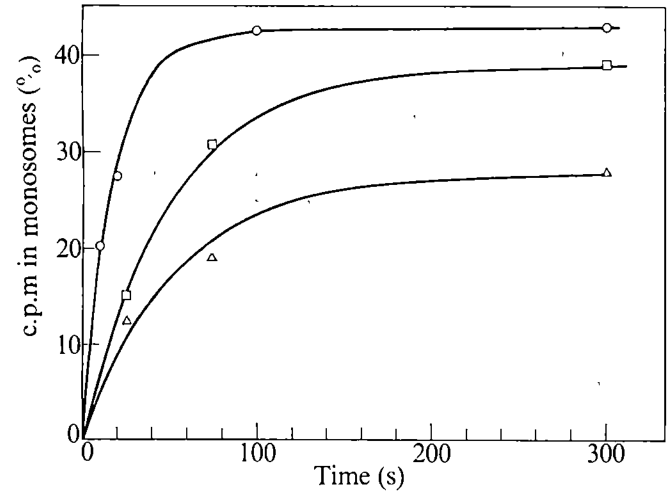

Fig. 6 Rate of binding of VSV mRNAs to reticulocyte ribosomes. Reactions (330 μl containing about 10^6 c.p m. of ^{32}P-labelled control VSV mRNA (○), periodate-treated RNA (□), or periodate-treated and β-eliminated RNA (△) were identical to those used in the study of Fig 5. Incubation was at 30 °C. At times indicated, 75 μl samples were added to 0.5 M HSB at 0 °C. Samples were layered on 13-ml linear 15–30% sucrose gradients in HSB and centrifuged for 3.4 h at 40,000 r.p.m. in the SW40 rotor at 4° C. Collection and counting was as in Fig. 5. The percentage of the radioactive RNA found in the 80S region of the gradient is plotted. A background of 2.1%, observed with unincubated samples, has been subtracted from each point. The solid curves are those of the first-order binding equation

$$C = C_\infty\left[1 - \left(\exp\frac{-t\ \ln 2}{t_{1/2}}\right)\right]$$

where C is the percentage of RNA bound to monosomes at time t, C_∞ is the maximum value of C, and $t_{1/2}$ is the time required for half-maximum binding of the RNA. For each RNA sample, C_∞ and $t_{1/2}$ were calculated by a least-squares program using the observed data points. These values are: control RNA, $C_\infty = 42\%$, $t_{1/2} = 11.7$ s, periodate-treated RNA, $C_\infty = 39\%$, $t_{1/2} = 34.6$ s; periodate-treated and β-eliminated RNA, $C_\infty = 28\%$, $t_{1/2} = 36.7$ s.

or absence of a 5′-terminal 7-methylguanosine as reported[12], then the results imply a more intimate involvement of 7-methylguanosine in translation of reovirus mRNAs than we observe for VSV mRNAs. This perhaps indicates a close proximity of the reovirus 5′ terminus to the translation initiation site, a situation already documented for the coat protein mRNA of brome grass mosaic virus[21].

We initially had great difficulty recovering translatable VSV mRNA after periodate-oxidation and β-elimination, and clearly did not completely overcome the problem of degradation. Thus, we suggest that similar studies indicating a requirement for 7-methylguanosine in translation of cellular mRNAs[11,22] should be more carefully controlled for possible nonspecific effects of the chemical procedure.

The model we favour is that in which the terminal 7-methylguanosine has different effects on translation of different mRNAs For some mRNAs, for example, poliovirus RNA and VSV mRNAs, it is clearly not essential, but it may facilitate ribosome attachment to VSV mRNA. For other mRNAs, a 5′-terminal 7-methylguanosine may be essential. It is also possible that wheat embryo ribosomes—used for much of the previous work—differ from animal ribosomes in their dependence on the 7-methylguanosine residue. Indeed, we have observed as much as a tenfold reduction in translation of periodate-treated, β-eliminated VSV mRNA in the wheat embryo system, perhaps indicating a more important role for 7-methylguanosine in this heterologous system. Thus, both the mRNA in question and the source of the translational components may be important factors in determining the effect of the 5′-terminal 7-methylguanosine.

We thank David Baltimore for suggestions on the manuscript, Barbara Small and Martin Brock for technical assistance, and Alan Weiner for suggesting control experiments with f2 phage RNA. This work was supported by grants from the American Cancer Society and the NIH. J.R. is recipient of a fellowship from the National Cystic Fibrosis Research Foundation, and H.F.L. was recipient of a research career development award from NIH.

X-ray pulses from globular clusters

GIANT X-ray pulses have been observed recently by several groups[1-7] from sources located in a number of celestial positions. Two of these sources may plausibly be identified with the globular cluster X-ray sources: NGC6624 and NGC1851. In several cases[2,7] the pulses seem to occur in approximately periodic sequences; in other sources the intervals are irregular, but in one case there is a relation between pulse strength and interpulse interval. The non-burst behaviour of globular cluster X-ray sources has been interpreted[8,9] in terms of massive ($\gtrsim 10^3 M_\odot$) black holes powered by accretion from a disk supplied by cluster gas. We suggest here that compact stars bound to the central massive black hole and orbiting through the accretion disk may produce, by several possible mechanisms, giant pulses. These pulses might be expected to exhibit a variety of types of X-ray behaviour corresponding to the uncertain characteristics (for example, density and spatial extent) of the individual accretion disks at the different points at which the orbits of the bound compact stars intersect the disks. We note that there may be more than one class of sources of giant X-ray bursts and that our speculation refers only to those sources in globular clusters.

We can easily estimate the expected orbital period of the star closest to the central black hole. The rate at which stars are captured has been computed by several authors[10-12]. It is to an order of magnitude, and neglecting dimensionless constants,

$$\dot{N} \lesssim \left(\frac{v_{\mathrm{r.m.s}}}{R}\right)_{\mathrm{core}} \left(\frac{M_{\mathrm{BH}}}{M_{\mathrm{core}}}\right)^{3} \simeq 10^{-7.0}(M_{\mathrm{BH}}/10^{3}M_{\odot})^{3}\ \mathrm{yr}^{-1} \qquad (1)$$

where 'core' refers to characteristics of the globular cluster core. (The rate at which the tightly-bound orbits relevant to the present discussion are populated may be less than this, but our results are, fortunately, insensitive to $\dot{N}$.) At small distances from the hole, gravitational radiation dominates the two-particle scattering and the drag caused by interaction with the disk. Stars with period, P, will spiral quickly towards the hole on a time scale

$$\tau_{\mathrm{rad}} \equiv \left(\frac{R}{\dot{R}}\right)_{\mathrm{GR}} = 10^{5.7}(M_{\mathrm{BH}}/10^{3}M_{\odot})^{-2/3} \times$$

$$\times (M_{*}/M_{\odot})^{-1}\left(\frac{P}{1\ \mathrm{h}}\right)^{8/3}\ \mathrm{yr} \qquad (2)$$

The time that a star spends at any given radius decreases rapidly with decreasing radius ($P \propto R^{3/2}$; $\tau_{\mathrm{rad}} \propto R^{4}$). Hence we find, by multiplying together equations (1) and (2), the period of the innermost stellar orbit that most likely contains one star

$$P \gtrsim 4(M_{\mathrm{BH}}/10^{3})^{-7/8}\ \mathrm{h} \qquad (3)$$

Thus a clock with a period of hours to one day is natural in this model, in agreement with observations[2,7]. (For main-sequence stars, tidal effects set a lower limit of this order to the orbital period.) Of course, the manifestation of this period requires various things about the accretion disk.

The duty cycle for 3U1820−30 is apparently very small ($\sim 10^{-3}$) so the interaction between the orbiting star and the disk would have to be relatively brief for this source, that is, a very thin disk ($\lesssim 10^{8.5}$ cm) would be required. At least two mechanisms for producing the pulses come to mind: (1) a small, hot, shocked area will be produced twice each orbit as the innermost star crashes through the disk. This might be seen directly: its properties will depend on whether it is caused by an ordinary star losing mass by tidal stripping and producing a bow shock (R. Silk, personal communication) or, more likely, a compact star producing an observable accretion wake; (2) ripples will proceed from the shocked zone towards the centre of the disk producing, when the wave train reaches the innermost stable orbit, extra accretion and luminosity. Depending on the orientation of the system with respect to our line of sight, and on whether or not the disk is optically thick to X rays, one would expect to see one or two pulses per orbital period. Irregularities and instabilities in the disk could produce the observed[2] r.m.s. phase jitter of $\lesssim 0.04$ per period.

There are certain additional observational consequences of this model: (1) globular clusters in our Galaxy can be far away ($\sim$10 kpc) so that one would not be surprised if some of the sources near the galactic centre or at low galactic latitude were associated with optically obscured globular clusters; (2) the galactic latitude dependence of the sources we consider should be similar to that of the known globular clusters except there may be a number of optically undiscovered X-ray globular clusters in the direction of the galactic centre (scale size $\sim$1 kpc by analogy with globular clusters in Andromeda); (3) more than one period per source might be found if there were more than one star orbiting near the hole. If this were discovered it would be difficult to explain on the usual binary hypotheses; (4) as noted previously[8], no eclipses should be seen according to this model and (5) a small odd–even effect caused by non-zero orbital eccentricity might be observable.

Frequency variation of equatorial ionospheric scintillations

The fluctuations in the signal strength of v.h.f. and u.h.f. transmissions from satellites received at ground level contain valuable information about ionospheric irregularities. These fluctuations, usually called scintillations, depend on the frequency of transmission, characteristics of the irregularities and the angle of incidence. At equatorial latitudes, there have as yet been few such observations, and there are reasons to expect the scintillation characteristics at equatorial latitudes to be quite different from those at higher latitudes because the ionospheric irregularities (mainly spread F irregularities) responsible for scintillations differ widely in their characteristics with latitude. It is also well recognised that the equatorial region is a strong scintillation zone. At Trivandrum (dip 0°57′S, geographic longitude 76°57′E), a station close to the magnetic equator, amplitude and phase scintillations of the radio beacon transmissions on 40, 140 and 360 MHz as well as the amplitude scintillations of the 860-MHz television downlink from the geostationary satellite ATS-6 have been recorded since August 1975. Here we present preliminary results on the frequency variation of the scintillation index.

In Fig. 1 a typical record of scintillations on all the four frequencies is shown. The records at 40 and 140 MHz are synchronous whereas those on 360 and 860 MHz are not. It is a general observation that scintillations are faster at lower frequencies. The quasi-periods of fluctuations are in the range of few seconds to few tens of seconds, the quasi-periods being shorter at lower frequencies. Also, scintillations occur more frequently and earlier in the night at lower frequencies. We here consider only nocturnal scintillations which can be attributed to the phenomenon of spread F. For this study, data recorded during six nights in the month of October 1975 have been used. Of these, scintillations were observed on four nights at all four frequencies and on the other two nights scintillations were observed on 40, 140 and 360 MHz only.

Using the amplitude scintillation data on all the frequencies, the S_4 scintillation indices[1] have been evaluated. For this, the length of the data sample considered corresponds to $\sim$10 min, which is sufficiently long not to cause any error in the S_4 indices, considering the quasi-periods of the fluctuations.

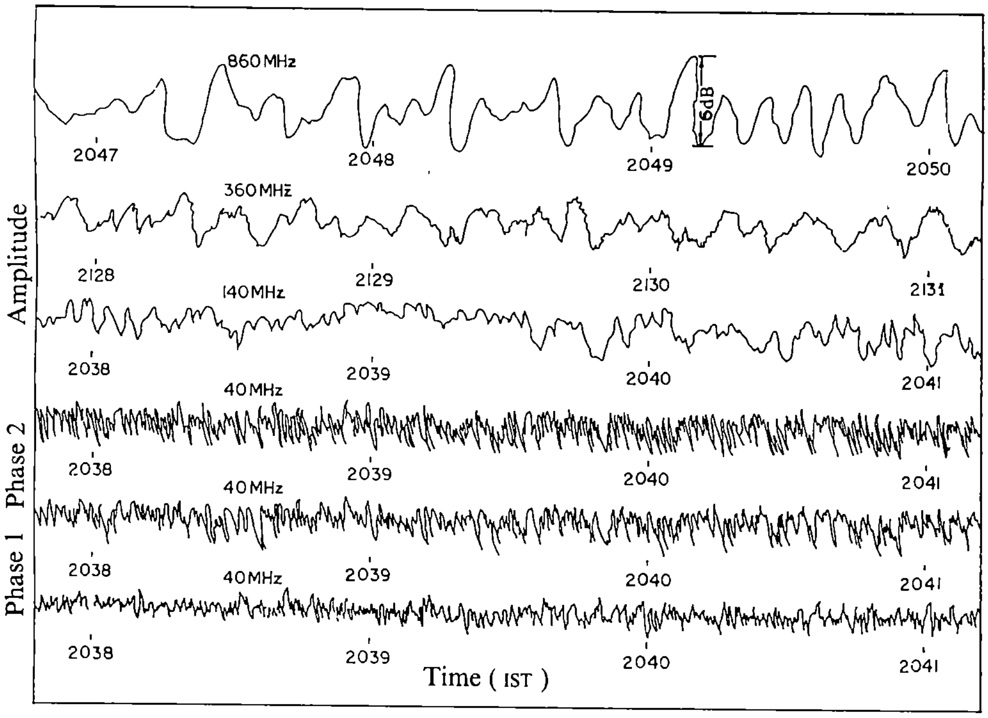

Fig. 1 Scintillations of ATS-6 transmissions recorded at Trivandrum. All traces taken on October 21, 1975 except the second (360 MHz), which was taken on October 24, 1975.

It is reasonable to assume that this interval is short enough for the scintillation characteristics not to vary within this interval except perhaps during onset and decay of scintillations. It may be noted that the onset and decay periods are not included in the present analysis.

The frequency variation of S_4 can be represented by

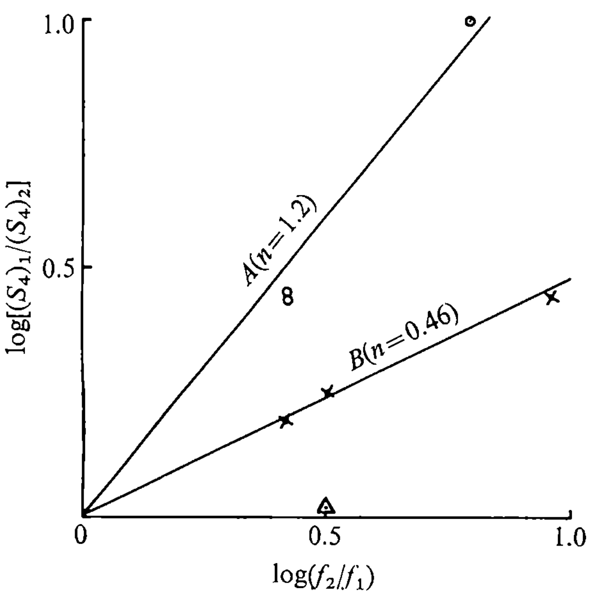
$$S_4 = \frac{K}{f^n}$$

where f is the exploration frequency, n is the frequency index and K is a constant depending on the scintillation conditions only. This equation can be rewritten as

$$\log_{10}\frac{(S_4)_1}{(S_4)_2} = n \log_{10}\frac{f_2}{f_1} \qquad (1)$$

where $(S_4)_1$ and $(S_4)_2$ are the scintillation indices corresponding to the frequencies f_1 and f_2. The quantities $\log_{10}[(S_4)_1/(S_4)_2]$ and $\log_{10}[(f_2)/(f_1)]$ are plotted in Fig. 2. It has been found that the points (circles and crosses in Fig. 2) fall around two straight lines having different slopes. The slope of line A is 1.2 and that of line B is 0.46. The line A corresponds to frequencies > 140 MHz whereas the line B includes data points at 40 but not 860 MHz. A careful examination of the data showed that the S_4 indices can be divided into two groups depending upon whether the S_4 index at 360 MHz is greater or less than ~0.5. The conditions corresponding to $S_4|_{360} > 0.5$ can be termed as strong scintillation conditions and those corresponding to $S_4|_{360} < 0.5$ as relatively weak scintillation conditions. The lines A and B (Fig. 2) represent weak and strong scintillation conditions respectively. It is also found that when the $S_4|_{140}$ is ~0.8, $S_4|_{40}$ is also about the same (the triangle point in Fig. 2) indicating no frequency variation of the S_4 index in the frequency range 40–140 MHz.

Fig. 2 Frequency variation of S_4 index.



Recently Rufenach[2] has shown theoretically that, for the weak scattering case, n is between 1.4 and 1.6 depending on the exponent of the irregularity spectrum in the range 3.5–4.5. The multiple scattering case has been considered on theoretical grounds by Yeh *et al.*[3]. They had shown that n is $\leqslant 1$ for lower frequencies and it approaches a value of 1.5 at higher frequencies. The results presented here seem to agree with these theoretical considerations. The transition from the low to high frequency index appears to occur in the frequency range 140–360 MHz. The reason for the low value of n obtained here for the weak scattering case as compared to that given by Rufenach[2] and Yeh *et al.*[3] is perhaps that line A (Fig. 2) representing the weak scatter case is somewhat vitiated by $S_4|_{140} > 0.5$. A more detailed discussion on the theoretical interpretation of these results will be presented elsewhere.

Ocean temperatures and large scale atmospheric variations

We here analyse some observations of sea surface temperatures to investigate several aspects of large scale ocean–atmosphere interactions, in particular El Nino and the Southern Oscillation

Monthly mean sea surface temperature observations for most of the Pacific Ocean between 50°N and 20°S for the period 1949–73 were given an empirical orthogonal function analysis based on values at 160 grid points, each centred in an area 10° longitude by 5° latitude[1]. This analysis produces orthogonal spatial functions and corresponding orthogonal time coefficients which are the best linear representations (predictors) of the data[2] The functions and coefficients may be thought of as analogues of the more familiar Fourier components and amplitudes, except that the empirical functions are determined from the interrelationships within the data itself.

Figure 1 illustrates the most important empirical function of the deviations of the sea surface temperatures from the 25-yr monthly means This function accounts for 23.1% of the total variance in the field. The temperature deviation explained (predicted) by this function for a given place and time is simply the product of the value of the function at that place and the value of the time coefficient for the month in question. The spatial pattern of this function reveals a large scale effect in which the equatorial and eastern Pacific vary in phase whereas the north-central and western Pacific are out of phase. The time series is a good measure of the occurrence and strength of the so-called El Nino (and its inverse), which is the name given to periods of warmer(cooler)-than-average water off Peru and along the equator.

The ultimate cause of the El Nino modulation is unknown, although it is believed to be closely linked to the equatorial wind-driven oceanic circulation. The pattern in Fig. 1 suggests an hypothesis for the termination of the equatorial warm-water periods. Higher equatorial sea-surface temperatures would tend to increase the rate of latent heat release in the tropical troposphere[3], and this may be associated with greater poleward atmospheric fluxes of heat and angular momentum[4]. These tendencies, coupled with an increased meridional subtropical atmospheric temperature gradient induced by the sea temperature anomalies, would result in strengthened mid-latitude westerlies and equatorial easterlies. The latter would act to increase cold upwelling along the equator and reduce the transport of warm water from the west towards Peru by the equatorial countercurrent[5]. The result would be the destruction of the El Nino conditions. A similar process was shown to be quite effective in increasing the easterlies in a numerical experiment by Rowntree[6]. This hypothesis is supported by the fact that, as indicated in Fig 1, El Nino generally ends in the Northern Hemisphere winter when the meridional fluxes in that hemisphere are a maximum[7]. Such a negative feedback would imply that any causal mechanism proposed for El Nino must incorporate a persistence sufficient to explain the 6–18 month existence of the warm conditions.

El Nino is closely related to or even a part of another phenomenon called the Southern Oscillation. The latter is a negative correlation of atmospheric pressure fluctuations in the south-eastern Pacific with those in the Indonesian region Lower pressures over the eastern Pacific tend to accompany warm water there and higher pressures over Indonesia. An empirical orthogonal analysis of tropical sea level pressure, temperatures, and rainfall by Kidson[8] shows the largest fraction of the longer term variability in these fields occurs in Southern Oscillation modes. Variations of the time coefficients of these modes are quite similar to those of Fig. 1 for the period of Kidson's study, 1951–60. We have also compared the entire record of sea temperature coefficients with the variations of sea level pressure at Darwin, Australia, which has been used as a simple index of the Southern Oscillation[9], for several lags and leads. The correlations at zero lag and when the sea temperatures lead the pressures by one month are both 0.55. The correlation when the pressure changes lead those of the sea temperatures by a month is 0.51, which is significantly different at the 95% confidence level.

Our sea temperature-time series also bears a remarkable resemblance to that of mean temperatures of the tropical troposphere recently reported by Angell and Korshover[10] for 1958–73, as shown in Fig 1 The only major discrepancy is for 1964–65 when the tropospheric temperatures remain below the mean whereas the sea temperatures are above In

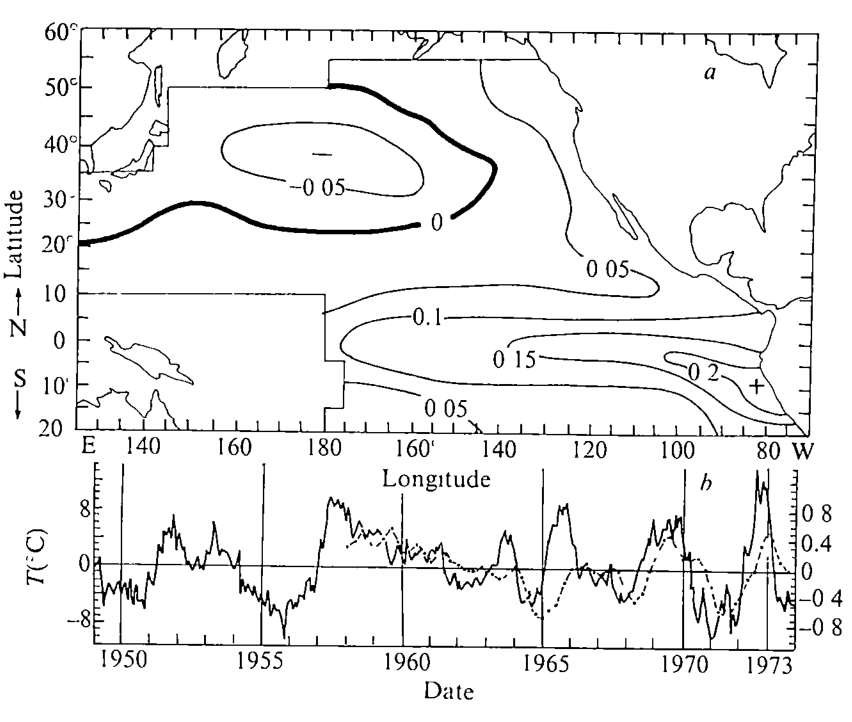

Fig. 1*a*, Empirical orthogonal function of sea-surface temperatures identifying the El Nino mode, and *b*, its corresponding time coefficients (solid line and left hand scale) and tropical troposphere mean temperatures (dotted line and right hand scale) The latter are derived from three-month means of 700–300 mbar thickness data for 14 stations situated near 20°N and 20°S, centred at January, April, July, and October[10]. Tics in the time series identify January of the respective year starting with January 1949 and ending with December 1973

fact, the correlation coefficient between the two variables is 0 74 for the whole period when the sea temperatures lead the air temperatures by 6 months This correlation increases to 0 80 when the years 1964–65 are excluded from the calculation Although there are several possible reasons for the breakdown in correlation in 1964–65, we discuss here only two. One hypothesis is that sea temperatures remain low during this period in other oceans thus holding tropospheric temperatures down. Preliminary results of an analysis of sea temperatures in the Atlantic indicate, however, a small warming rather than cooling during 1965. A second hypothesis is that the difference is associated with a surface cooling resulting from the large increase in stratospheric aerosol which followed the eruption of Mt Agung in March 1963 The additional aerosol was associated with a temperature increase in the tropical stratosphere of 2–6 °C which took several years to disappear[11] Direct solar radiation measured at the ground was concomitantly diminished[12] Since the middle tropical troposphere is mainly heated through latent heat liberation which is decreased during periods of reduced solar surface heating, part of the tropospheric cooling in 1964–65 could probably be ascribed to the effects of Mt Agung. The magnitude of that effect remains an open question

In addition to the six month phase lag which we have shown exists between tropical sea surface and tropospheric temperatures, Angell and Korshover report that tropospheric temperatures at high latitudes change six months later than those in the tropics. Although there are a number of possible factors that may introduce these lags, such as meridional oceanic transport processes and polar ice cap changes, separation of cause and effect is not possible at this time. Careful diagnostic studies and continuous monitoring of both ocean temperatures and volcanic eruptions, however, may enable us to use these phase lags to advantage in seasonal forecasting.

We thank the NSF and ERDA for support and John Kidson for a helpful review We also thank Alfredo Navato for his contribution.

Long term variations in western tropical Pacific cyclogenesis associated with the Southern Oscillation

THE 'Southern Oscillation', as statistically defined by Sir Gilbert Walker, is the barometrically recorded exchange of air mass in tropical latitudes around the complete circumference of the globe[1,2]. Indices of Southern Oscillation based on the surface pressure differences between the Indonesian equatorial low (measured at Darwin, Australia) and the South Pacific subtropical high (considered the Southern Oscillation's eastern core and measured at Easter Island) have been used by Quinn[3–5], who relates fluctuations in these indices to anomalous equatorial rainfall and occurrences of 'El Niño', (the accumulation of anomalously warm water in the eastern tropical Pacific). In this paper, we use 12-month running means of monthly mean surface pressures over three areas across the northern tropical Pacific as an index of the Southern Oscillation index, and we find that pressure convergences in this index are associated with years of relatively low numbers of western Pacific tropical cyclones.

Bjerknes[2] describes a major mechanism in the operation of the Southern Oscillation in the zonal atmospheric circulation which occurs over the equatorial Pacific between the ascending branches of the Hadley cells of the North-east and South-east Trade Winds. The normal sea surface temperature condition of warm water in the western tropical Pacific and cooler water (caused by equatorial upwelling and South American coastal upwelling) in the eastern tropical Pacific drives a zonal convective circulation along the equator between these two regions The distinguishing feature of this particular east–west flow is the potential energy release involved in the dry descent of colder air over the eastern and central tropical Pacific combined with the ascent of warm moist air over the western tropical Pacific.

Anomalous warming of the eastern tropical Pacific sea surface has been related by Wyrtki[6] to increased transport of warm western tropical Pacific water into the eastern tropical Pacific by means of the equatorial countercurrent. These eastern tropical Pacific warmings, in the extreme being referred to as 'El Niño', seem to occur aperiodically from 2 to 7 yr apart The resultant decrease in equatorial sea surface temperature gradient across the Pacific reduces or halts the Walker Circulation, and is associated with the decrease of Southern Oscillation index, that is, a reduction of the difference between surface pressures at Darwin, Australia and Easter Island. What initiates a warming trend is not yet understood.

The situation of a well established Walker Circulation, with the ascent of warm moist air in the tropical western Pacific over a warm sea surface, enhances the first of the three conditions required for intense tropical cyclone formation As described by Palmen and Newton[7], the three conditions are "(1) Sufficiently large sea areas with a water temperature so high that moist air lifted from the lowest layers of the atmosphere (with almost the temperature of the sea surface), expanding pseudo-adiabatically, remains considerably warmer than the surrounding undisturbed atmosphere at least up to a level of ~ 12 km. (2) A Coriolis parameter larger than a certain minimum value, thus excluding a belt of ~ 5° to 8° latitude on either side of the equator. (3) Weak vertical wind shear and correspondingly, weak baroclinity in the basic current in a deep tropospheric layer"

Ramage[8] further notes that over the Pacific, near-equatorial troughs coincident with sea surface temperature maxima are the primary spawning grounds of almost all hurricanes The preconditions of Palmen and Newton[7] are then related to these troughs. Condition (1) is satisfied along the trough axis with the warmest sea surface temperature. Condition (2) is satisfied when the trough is > 5° from the equator where vortices can develop. Condition (3) is also satisfied, since weak vertical shear occurs above the sea surface temperature maximum associated with the trough axis.

It can be reasoned that a strong convective Walker Circulation, driven by the thermally derived pressure gradient between the warm western equatorial Pacific and

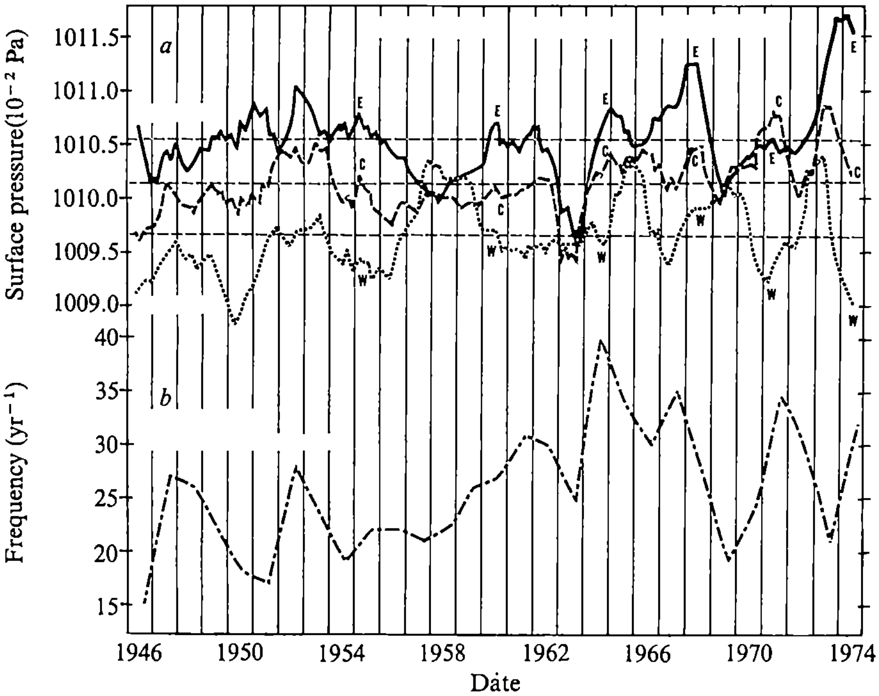

Fig. 1 Time series (1946–74) of 12-month running mean surface pressures (10^{-2} Pa, 1Pa = 10^{-5},bar) for EASTROPAC (E), CENTROPAC (C), and WESTROPAC (W) and *b*, frequencies of western Pacific tropical cyclones.

a cooler eastern equatorial Pacific, might reinforce the conditions of tropical cyclone development in the near-equatorial trough in the western Pacific.

The question thus arises whether an eastern tropical Pacific sea surface temperature warming with the resultant decline in Walker Circulation and decreased ascent of warm moist air in the tropical western Pacific can be associated with a decline in the total number of tropical cyclones in the western Pacific for the given 'warming' year.

Twice-daily surface pressure analyses from 1946 to 1974 were used in the present study. The data were digitised in a 63×63 polar stereographic grid (grid size at 60°N is 381 km). The manually analysed charts were digitised at the National Climatic Center (1946–55, 1960–62) and in the National Center for Atmospheric Research (1956–59). From January 1963 onwards, the numerically analysed surface pressure charts from Fleet Numerical Weather Centre were used. The properties of these digitised surface pressure data are further described by Larson[9].

Monthly means of surface pressure are computed for each grid point and each individual month, with emphasis mainly on three areas in the tropical Pacific in a latitudinal band, 0° to 15°N: The EASTROPAC area reaches from the Central American coast to 150°W; the CENTROPAC area lies between 150°W and 165°E; and the WESTROPAC area extends from 165°E to the Asian coast. The 0° to 15°N latitudinal band includes the main portion of the northeast tradewind zone, north equatorial current, and equatorial countercurrent The monthly means as well as 12-monthly running means of surface pressure are computed for these three different areas; the 12-month running means are computed to eliminate most of the seasonal cycle and depict the long term (> 1 yr) changes.

Plotted together (Fig 1*a*) the 12-month running mean surface pressures converge and diverge in good agreement with Quinn's[3–5] Southern Oscillation index and Wyrtki's[6] equatorial countercurrent index (Harding and Larson[10]). This indicates that the data represent a manifestation of the Southern Oscillation, north of the equator.

The total numbers of tropical storms plus typhoons in the western Pacific for each year, 1946–74, according to Hamilton[11], are plotted to give a measure of interannual variations in tropical cyclogenesis

More rigorous data treatment is not attempted because of the variety of available sources of pressure analyses and of the increased detectability of tropical cyclones with the advent of satellite meteorology in recent years.

Figures 1*a* and 1*b* present the 12-month running mean surface pressure plots for EASTROPAC, CENTROPAC and WESTROPAC as well as the yearly tropical cyclone numbers. The convergences of surface pressure between EASTROPAC and WESTROPAC (associated with EASTROPAC sea surface temperature warming (Wyrtki[6], Harding and Larson[10])) since 1956 are associated with the minima in the number of tropical cyclones in the corresponding years. This is as expected, in as much as these pressure convergences indicate decreases or stoppages of Walker Circulation, and the resulting decrease in the amount of warm moist air ascending in the tropical western Pacific. Also to be noted are the tropical cyclone maxima occurring with the greatest EASTROPAC–WESTROPAC pressure differential, which indicate strong Walker Circulation and well maintained ascension of warm moist air in WESTROPAC.

The results of this study indicate that fluctuations in the Southern Oscillation seem related to interannual variations of tropical cyclogenesis in the western Pacific. The mechanism which connects these phenomena is probably the large scale release of potential energy caused by the thermally driven equatorial Walker Circulation High pressure differential between the EASTROPAC and WESTROPAC represents good Walker Circulation and is associated with interannual maxima in western tropical Pacific cyclogenesis. Pressure convergence of EASTROPAC and WESTROPAC represents little or no Walker Circulation, and is associated with tropical cyclone minima

I thank Mr S. Larson, for providing the data on which Fig. 1*a* is based; Dr T. Laevastu, for advice; Ms W. Carlisle and Ms M. Dimock, for typing; Mr R. Clark, for drafting Fig. 1*a* and *b*, and Mr S. Bishop, for editorial assistance.

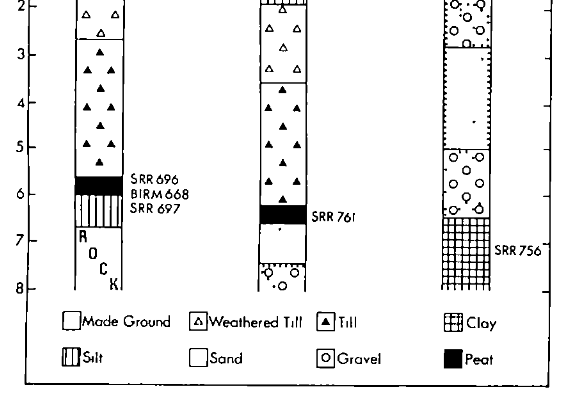
Three late-Devensian sites in West-central Scotland

Preliminary investigations of late-Devensian sediments that include moss-sedge peat and moss detritus suitable for radiocarbon dating indicate movement of thick layers of till on the sides of drumlins in west-central Scotland since ~11,150 b.p. Two of the sites investigated are in inter-drumlin depressions on the north-eastern side of Glasgow: at Springburn (NS 609678) and Robroyston (NS 633676). The third site is between Paisley and Irvine on the floor of the Lochwinnoch Gap at North Kerse (NS 339556). The Quaternary sedimentary sequences at the three sites are shown in Fig. 1

At Robroyston the silt underlying the till contains sparse fruit stones of a pondweed, *Potamogeton* cf. *pectinatus* L., a submerged aquatic plant of base-rich water, but virtually no pollen Abundant remains of the algae *Botryococcus* and *Pediastrum* were found with a spore of the terrestrial, calcicolus moss genus *Encalypta* and numerous derived Carboniferous spores The peat, composed of the moss *Scorpidium scorpioides* (Hedw) Limpr. (another indicator of base-rich water) and a sedge (*Carex* sp), has a pollen flora overwhelmingly of Cyperaceae but wtih 13 other taxa of herbs and dwarf shrubs (Table 1). The radiocarbon-dated material was the *Scorpidium–Carex* peat which, on careful examination, showed no Carboniferous contamination.

The lower peat at Springburn, consisting of pure *Scorpidium scorpioides,* has a pollen flora fundamentally similar to that of Robroyston in its large proportion of Cyperaceae, its range of herbs and its very low proportion of trees (Table 1). The upper peat contains mixed oak forest pollen with high *Alnus, Corylus* and ferns. The lower radiocarbon-dated sample was the *Scorpidium* peat (no sign of Carboniferous contamination) and the upper was a highly decomposed peat.

Fig. 1 Late-Devensian sedimentary sequences at sites investigated at Robroyston, Springburn and North Kerse, based on borehole records (all three sites) and observations in excavation pits (Robroyston and Springburn) The locations of radiocarbon dated samples within the sequences are indicated by the relevant laboratory numbers Dates (in yr) are· SRR 696, 11,653 ± 190; BIRM 668, 11,210 ± 150; SRR 697, 11,265 ± 125, SRR 760, 5,994 ± 50; SRR 761, 11,140 ± 110 and SRR 756, 11,210 ± 190.



The two sub-till peats, from Robroyston and Springburn, indistinguishable in age and very similar in botanical content, point to identical, if perhaps very local, environments —wet tundra of a rich fen type in the inter-drumlin hollows, possibly with the adjacent grassy slopes bearing heliophilous herbs such as *Helianthemum* and *Artemisia.* Very little is known, as yet, of the late-Devensian vegetation of west-central Scotland, but it is now evident that rich fens with *Scorpidium* and *Carex* were widespread during the Allerød oscillation; there are previous records from Garscadden Mains (NS 524712), just West of Glasgow[1,2], and from Drymen (NS 490923) near Loch Lomond[3]

Table 2 lists the macroscopic plant assemblage sieved from ~ 500 ml of the clay at North Kerse. The assemblage is mainly, if not entirely, allochthonous. By far the most abundant fragments are of the moss *Rhacomitrium aruginosum*, an often abundant colonist of freshly exposed rock or mineral soil *Aulacomnium turgidum* is a common tundra moss, now rare in the Scottish mountains. This species and *Alchemilla vulgaris* agg. have few Quaternary records, the other taxa are well known from the British Quaternary[2,4] The material used for radiocarbon dating consisted of fragments of *Rhacomitrium* with a slight admixture of vascular plant debris Abundant small fragments of coal were separated by flotation and by manual removal under a dissecting microscope.

The evidence from the three sites may be synthesised as follows:

(1) At Robroyston and Springburn, glacial till on the flanks of drumlins overlies peat deposits dated ~ 11,650–11,150 b.p and containing flora indicative of tundra conditions The till in contact with the organic deposits is unweathered and resembles the typical grey till constituting the drumlins of central Glasgow[5], till that is commonly regarded as a product of the main Devensian glaciation, thought to have occurred in west-central Scotland broadly between 27,000 and 13,000 b p.

(2) At Springburn the till underlies peat dated 5,994± 50 b.p. and therefore must have been emplaced in its present position by natural processes rather than by the industrial activities of man. Inferentially, the till at Robroyston also was transported to its present position by natural processes.

(3) At North Kerse, the plant detritus dated 11,210± 190 b.p is indicative of tundra conditions The detritus is overlain by sands and gravels which, on initial investigation, are thought to have been deposited in an aqueous environment

Possible alternative interpretations of the evidence are these

(1) The till at Robroyston and Springburn was deposited directly by ice in its present positions in the course of a glaciation that occurred later than ~ 11,150 b.p The tundra conditions indicated by the peat deposit at Robroyston, the lower peat at Springburn and the dated organic detritus at North Kerse may represent the onset of colder, glacial conditions in west-central Scotland after a warm episode ~ 13,000–12,000 b p. (ref. 6) At North Kerse, the sands and gravels overlying the organic detritus may have been deposited penecontemporaneously with the till in a periglacial regime outside the area of glaciation at Robroyston and Springburn.

(2) After initial deposition by glacier ice, the till at Robroyston and Springburn was moved to its present positions by solifluction processes while contemporaneously the sands and gravels at North Kerse were deposited in a periglacial environment during a cold period that commenced ~ 11,200 b.p. (cf. the commonly recognised cold episode in Britain between 11,000 and 10,000 b.p.; with average July

The first interpretation must be considered improbable on the grounds that first, in western Glasgow and its environs, grey till constituting drumlins, apparently of the same swarm as those at Robroyston and Springburn, is overlain at a number of locations by marine deposits containing mollusc shells dated 12,600–12,400 b p (ref. 7), and second, there is no known evidence to suggest that in west-central Scotland the ice margin of the Loch Lomond Readvance (maximum ~ 10,500 b p.) extended beyond the southern flank of the Loch Lomond Basin[8].

The second interpretation lends support to suggestions recently made regarding late-Devensian climatic conditions in Britain, and focuses attention on a number of interesting problems awaiting further investigation. According to Sissons[9], major periglacial features in Scotland seem to be restricted to the area outside the limit of the Loch Lomond Readvance, and such features are indicative of extremely severe climatic conditions that persisted down to sea level[10]. Published evidence of periglacial action in Scotland during the Loch Lomond Readvance consists mainly of solifluction and associated phenomena in the Highland region together with the record of fossil frost wedges in the Midland Valley and, to a lesser extent, in the Southern Uplands. The evidence from Robroyston and Springburn strongly suggests that large scale solifluction on the flanks of drumlins with a major feature of periglacial activity in west-central Scotland in the cold period that commenced ~ 11,000 b.p. and culminated in the Loch Lomond Readvance. Previously, minor solifluction on the slopes of drumlins has been considered probable, but the sites at Robroyston and Springburn provide the first evidence in west-central Scotland of mass movement of till several metres thick Clearly, because these examples of such movement exist, many more may be discovered in the future The presence of a datable peat layer below the soliflucted till at Robroyston and Springburn allowed the movement of the till to be deduced There may be many situations on the flanks of drumlins where adjacent peat layers did not accumulate before the Loch Lomond Readvance, but solifluction of large till masses occurred nevertheless. Such cases will be very difficult to detect. Till-fabric and till-fissure analyses[11] may prove effective in some situations At Robroyston and Springburn preliminary studies of these properties of the till proved inconclusive.

Future research arising from the preliminary study of the three sites may be directed to establishing the vegetational evidence for late-Devensian climatic conditions in west-central Scotland, to assessing the effectiveness of till-fabric and till-fissure analyses in determining mass movement of till on the sides of drumlins, and to considering the modifications of drumlin shapes that occur as the result of till solifluction.

The authors thank W. Bradford and E. McKinnon (Preconstruction Services), for providing borehole logs and peat samples from Springburn and Robroyston. The plant sample from North Kerse was collected by R Ward. Five radiocarbon dates were provided by the Scottish Universities Research and Reactor Centre and paid for by the University of Glasgow. One date was provided by Birmingham University Mrs C A. Dickson and Mr D. A. Stewart assisted with the botanical analyses.

Changes in net surface charge of hydrous alumina with phosphate adsorption

ADSORPTION of phosphate on hydrous metal oxides is of considerable importance in soil fertility and eutrophication studies. Phosphate is known to be adsorbed on the hydrous oxides displacing aquo (M–OH$_2$) and hydroxo (M–OH) ligands; its adsorption makes the oxide surface less positive[1–3]. I report here on a quantitative study in which phosphate was adsorbed on to hydrous oxides, displacing the ligands, and the simultaneous change in the net surface charge was measured.

The hydrous alumina used has been described elsewhere[3] and the pH value at the point of zero charge (PZC) was 9.3. The phosphate adsorbed and the hydroxyl ions released at different phosphate concentrations were measured at a constant pH (see ref. 3). The experimental conditions were: pH 5.0; 0.01 mol dm^{-3} NaCl medium; 3 h reaction time; 30 °C; nitrogen atmosphere. The pH was chosen so that phosphate existed in solution as the monovalent ion. The net surface charge (σ) was calculated from the counter ions retained by the oxide in the diffuse double layer (details will be published elsewhere).

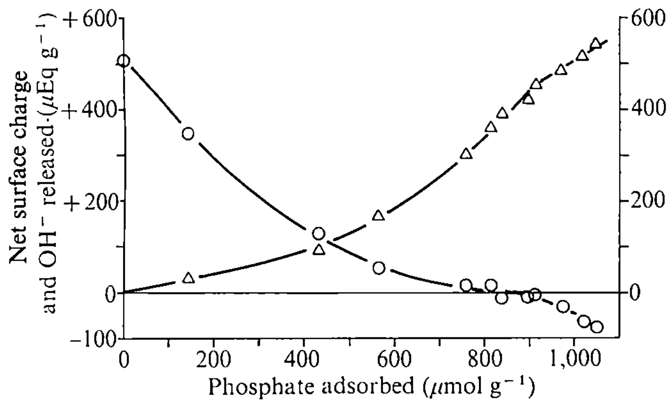

Fig. 1 Phosphate adsorption on hydrous alumina. Net surface charge (○) and OH$^-$ released (△) plotted against P adsorbed.

The hydroxyl ions released, and the σ values, are plotted against phosphate adsorbed in Fig. 1. Mathematical analysis of the hydroxyl ion curve shows that the differential (dOH$^-$/dP) increases with increasing phosphate adsorption from 0.11 to a maximum of 1.0 at about 900 μmol g^{-1} of phosphate adsorbed. At more than about 900 μmol g^{-1}, however, it abruptly decreases to 0.5 and remains constant.

The σ of the sample in the absence of phosphate (σ_0) was 507 μEq g^{-1} of positive charge. With increasing phosphate adsorption, σ decreased to zero, and with further adsorption it became negative.

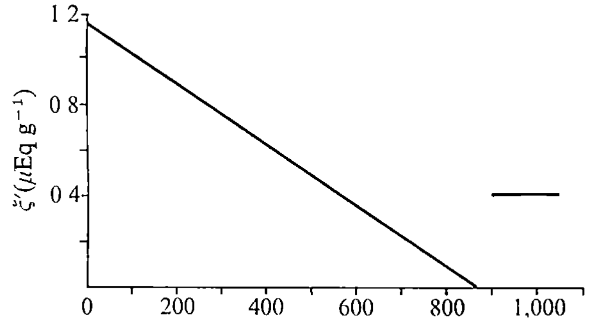

Fig. 2 Net charge acquired by the surface per unit μmol of phosphate adsorbed (ξ′) as a function of phosphate adsorbed.

At pH values more acid than the PZC pH, phosphate is probably adsorbed at the positive sites displacing OH$_2$, and at the neutral sites, effectively displacing OH$^-$ (refs 1–3).

$$\mathrm{Al\text{-}OH_2]^{1+} + H_2PO_4^- \rightleftharpoons Al\text{-}H_2PO_4]^0 + OH_2} \tag{1}$$

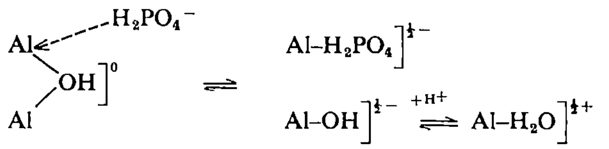
$$\mathrm{Al\text{-}OH]^0 + H_2PO_4^- \rightleftharpoons Al\text{-}H_2PO_4]^0 + OH^-} \tag{2}$$

Reaction (1) neutralises the positive charge, whereas reaction (2) leaves the surface charge unaltered.

Because of the greater lability of aquo groups, at low surface saturation more of these are displaced by phosphate, whereas with the increasing saturation the proportion of hydroxo groups released increases[3]. Therefore, the neutralisation of the positive charge would be initially rapid; this is seen from Fig. 1. There is little change in the σ within the phosphate adsorption range 800–900 μmol g^{-1}, and phosphate is adsorbed mostly by displacing hydroxyl ions, as is evidenced by the dOH/dP value of close to 1.

The net charge acquired by the surface per μmol of phosphate adsorbed (ξ′) at different adsorption values (Fig. 2) was calculated: the total net charge acquired by the surface, ξ ($\xi = \sigma_0 - \sigma_P$; σ_P = net charge on P added sample) was plotted as a function of phosphate adsorbed, and the equation that gave the best fit was differentiated. The differential curve (Fig. 2) shows that ξ′ varies with the type of ligand, OH$_2$ or OH$^-$, displaced by phosphate, which in turn varies with the surface saturation. These results suggest that earlier conclusions[4–6] that ξ′ is independent of surface saturation were based on observations of an experimental artefact. Other researchers have used either a titration method or have relied on separations of the phosphated sample from the matrix, followed by re-equilibration with another indifferent salt solution and extraction of the counter ions using yet another salt solution. It is likely that these methods would result in desorption and/or rearrangement of adsorbed phosphate.

The abrupt change in the slope of Fig. 1 at about 900 μmol g^{-1} phosphate adsorbed could signify[3,7] the disruption of hydrous alumina polymers. The fresh surface thus exposed would adsorb phosphate:



$$\mathrm{Al{\leftarrow}H_2PO_4^-,\ Al_2OH]^0 \rightleftharpoons Al\text{-}H_2PO_4]^{\frac{1}{2}-}\ \ Al\text{-}OH]^{\frac{1}{2}-} \overset{+H^+}{\rightleftharpoons} Al\text{-}H_2O]^{\frac{1}{2}+}}$$

$$\mathrm{Al\text{-}H_2O]^{\frac{1}{2}+} + H_2PO_4^- \rightleftharpoons Al\text{-}H_2PO_4]^{\frac{1}{2}-} + H_2O} \tag{3}$$

According to reaction (3) a net negative charge of 1 μEq is added for every 2 μmol of phosphate adsorbed. Thus, in the region of high phosphate adsorption (> 900 μmol g^{-1}) the expected ξ′ is 0.5, and the experimental value of 0.41 (Fig. 2) is in reasonable agreement.

Reactions (1) and (2) predict a 1:1 ratio between released OH$_2$ and ξ values. To test this, ξ values have been plotted against the number of μmol of OH$_2$ displaced (Fig. 3). The latter values were calculated from the difference between the amount of phosphate adsorbed and hydroxyl ions released. The four observations at > 900 μmol g^{-1} of phosphate adsorbed were not used because adsorption was on the new surface in that region, and different reaction paths are involved (3). The observed slope of 1.03±0.05 (r^2 = 0.989) agrees with the predicted value of 1.0.

The results presented add further evidence in support of the theory[3] on the nature of phosphate adsorption at different surface saturation values.

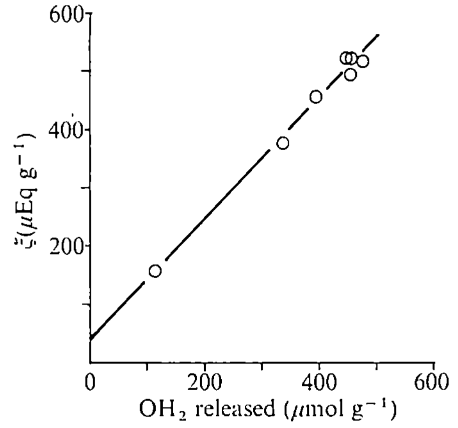


Fig. 3 Relationship between the net charge acquired (ξ) and aquo groups (OH_2) displaced by phosphate. $\xi = 40.46 + 1.03OH_2$; $r^2 = 0.989$.

I thank Dr J. H. Watkinson for correcting the manuscript, Mr D. M. Duganzich for statistical analysis, and the members of the Spectrolab for sodium determinations.

Conformational effects in drag reduction by polymers

An earlier study of drag reduction by polyelectrolyte solutions[1] revealed that the gross flow behaviour varied between extremes, termed types A and B, respectively characteristic of the collapsed and extended macromolecular conformations Here I show, from examination of all available experiments[1-5], that the crossover from type A to type B behaviour occurs at a characteristic conformation, which possibly reflects the role of macromolecular elasticity in the mechanism of drag reduction.

It should be recalled[6] that drag reduction by dilute polymer solutions in turbulent pipe flow is bounded between two universal asymptotes, that is, the Prandtl-Karman law and the maximum drag reduction aysmptote, that envelop a 'polymeric' regime in which the observed friction factor relations are approximately linear on coordinates of $f^{-1/2}$ against log $Ref^{1/2}$, where f is the friction factor and Re the Reynolds number. The behaviour exhibited by a family of polymer solutions is termed type A when the polymeric regime segments fan outwards from a common onset point on the Prandtl–Karman (Newtonian) line with slopes exceeding the Newtonian value and increasing with increasing polymer concentration, and type B when the polymeric regime segments lie roughly parallel to the Prandtl–Karman line but displaced upward from it, the more so with increasing additive concentration.

The dependence of a drag reduction modulus, κ, on a macromolecular excluded-volume parameter, E, is now sought from experimental data, these quantities being defined

$$\kappa = (\delta/c^{1/2})M^{1/2}N^{-3/2} \qquad (1)$$

$$E = \sigma\,([\eta]/[\eta]_\theta)^{1/3} \qquad (2)$$

κ is derived from friction factor measurements; δ is the observed Prandtl-Karman slope increment relative to solvent in the polymeric regime of drag reduction while c, M, and N, are respectively the macromolecular concentration, molecular weight, and skeletal links. E is formed from the polymer species chain conformation factor σ and the ratio of actual to theta point intrinsic viscosities, at zero shear, of the macromolecule; as long as the macromolecule remains random-coiling, E is evidently the ratio of actual to unhindered r.m.s. radii of gyration ($R_G/R_{G,of}$). The results are shown in Fig. 1, which shows κ against E on doubly logarithmic coordinates. An abrupt change in κ is observed at $E_x = 6 \pm 1$, defining a characteristic 'crossover' conformation. For $E < E_x$, in the region of type A gross flow behaviour, the drag reduction modulus is essentially independent of macromolecular conformation, and the examples in Fig. 1 all display magnitudes of $\kappa_A = 10^{-4}$, typical of random-coiling polymers with polymethylene types of skeleta[5]. For $E > E_x$, in the region of type B gross flow behaviour, the variation of κ with E cannot be ascertained for lack of data, but values of $\kappa_B = 10^{-5}$ are clearly an order of magnitude lower than κ_A. The behaviour described is well illustrated by results for two PAMH polymers in Fig. 1, one of which[1] yields $\kappa \times 10^6 = (61, 60, 61, 5, 5)$ for $E = (3.6, 3.7, 4.9, 6.8, 10.0)$ respectively while the other[2] (hollow squares) shows a very similar trend. The data[3,4] for random-coiling PEO and PIB polymers in good as well as in theta solvents both yield κ essentially independent of E over small ranges of $E < E_x$.

A possible physical interpretation of these results involves macromolecular rubber elasticity. E refers to the static (zero shear) conformation of a macromolecule in dilute solution. In

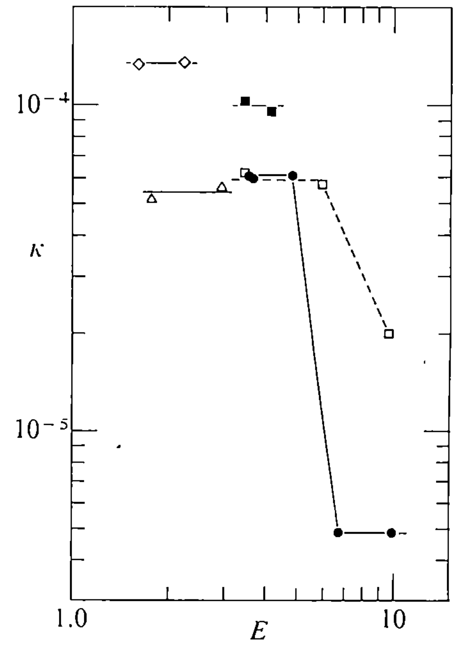

Fig. 1 The dependence of drag reduction slope modulus on macromolecular excluded volume

Symbol	Polymer	σ	Molecular weight ($\times 10^{-4}$)	Solvents	Pipe internal diameter (mm)	Reference
●	PAMH	2 30	15 2	Aq NaCl, 0–1 M	9 45	1
□	PAMH	2 30	9 2	Aq NaCl, 0–1 M	10 2	2
■	PAMH	2 30	7 8	Aq NaCl, 0 2–1 0 M	10 2	2
◇	PEO	1 60	0 76	Aq K_2SO_4, 0–0 6 M	4 57	3
△	PIB	1 82	0 89	Benzene, Cyclohexane	12 9	4

PAMH, Polyacrylamide, partially hydrolysed, PEO, polyethyleneoxide, PIB, polyisobutylene turbulent flow, a macromolecule suffers deformations about its mean conformation and the drag reduction modulus, κ, seems related to rubber elasticity[5] through a macromolecular chain deformation factor J, defined by

$$J = [(R_G'/R_G) - 1]/\beta^2 \qquad (3)$$

where R_G' and R_G respectively refer to deformed and mean conformations, whereas β is a non-dimensional strain rate. This suggests that the data of Fig. 1 arise because the elasticity of a macromolecular random coil is essentially independent of its excluded volume up to a certain conformation, E_x, and then decreases significantly for $E > E_x$. In this context, recent direct measurements of macromolecular extension in a Borda flow[6] are noteworthy. For two samples of PIB in decalin ($E \simeq 3$), it was found that at low strain rates the observed principal axis extension ratio (R_G'/R_G) yielded values of $J \simeq 10^{-1}$, of the order of magnitude theoretically predicted[7]. With increasing strain rate, however, the principle extension ratio tended to an asymptote with a maximum value $(R_G'/R_G) \simeq 3.5$, with corresponding lower values of $J \simeq 10^{-3}$. These experiments independently suggest that there is a characteristic macromolecular extension beyond which elastic deformation of the random-coil becomes difficult. Interestingly, the value of $R_{G,\mathrm{max}}'/R_{G,\mathrm{of}}(\sim 10)$ for PIB in a Borda flow is of the order of magnitude of our $E_x(\sim 6)$ obtained with PAMH during drag reduction, both of the polymers used possessing similar (but not identical) polymethylene skeleta.

Effect of drag-reducing polymers on pulsation noise of small air bubbles

PREVIOUSLY we have reported[1] that polyethyleneoxide (Polyox) in solution reduced the damping of free oscillations in a semi-circular manometer, whereas polyacrylamide (Separan: also an effective drag-reducer in turbulent flow) did not. Here we report the effect of these additives (Polyox grades WSR 301 and N3000; Separan grades AP 30, AP 273 and MG 200) on the pulsation noise radiated by small air bubbles in water.

The bubbles were produced by passing air through a submerged nozzle in a steel water-tank, 75 × 60 × 70 cm, which was mounted on an expanded polystyrene sheet (5 cm thick), on a concrete base. The compressed air supply consisted of a piston sliding in a cylinder. This was driven by an electric motor through a reduction gear which turned a threaded rod. The air outlet from the cylinder was connected by a flexible PVC tube to a brass nozzle, situated 23 cm below the water level, and mounted in a rubber bush to prevent resonance with the supporting rod. All the nozzles used were 7.5 cm long by 6.4-mm outside diameter, but the inside diameter varied between 2 and 5 mm to give a range of bubble sizes. This arrangement produced bubbles of uniform size at regular intervals. The average bubble size was determined from the volumetric displacement of the piston in the cylinder and the number of bubbles produced in a given time.

The bubble pulsation noise was detected by a hydrophone (Bruel and Kjaer type 8101: uniform frequency range up to 60 kHz), which was fixed at the same depth as the nozzle, but could be moved horizontally. The hydrophone was connected to a spectrum analyser (B and K model 2107). The output of the spectrum analyser was connected to a counter–timer (Bradley Electronics 234) used to determine bubble size and frequency of production, a storage oscilloscope (Tektronix 434) used for frequency spectrum and spatial attenuation measurements and an oscillograph (Bell and Howell model 5–137) used for measuring time-decay curves.

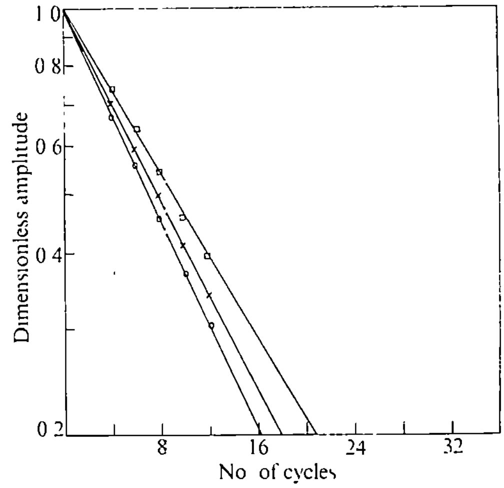

Fig. 1 Time decay of bubble pulsation noise. (Nozzle internal diameter 5 mm; bubble diameter 5.8 mm; f_0 (theoretical) 1,115 Hz; f_0 (experimental) 1,105 Hz). ×, water; □, 20 p.p.m. Separan AP 273; ○, 100 p.p.m. Separan AP 273.

Experiments were performed using nozzle diameters of 2, 3, 4 and 5 mm. In each case the additives affected bubble production. We found that at low concentrations, Polyox reduced bubble size (in agreement with previous results[2] on bubble growth in solutions of WSR 301) whereas Separan tended to increase the size of the bubbles. In both cases the effect was quite small, and the bubble radius quickly became independent of increasing additive concentration. Correspondingly the additives had only a small effect on the natural frequency of the bubble noise.

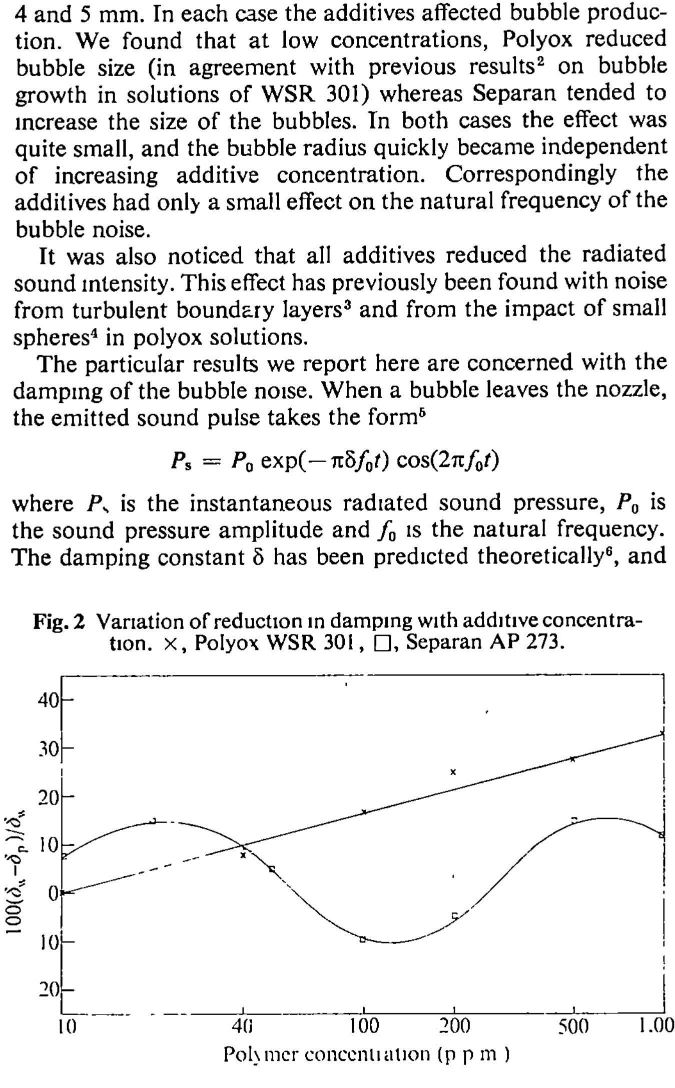
It was also noticed that all additives reduced the radiated sound intensity. This effect has previously been found with noise from turbulent boundary layers[3] and from the impact of small spheres[4] in polyox solutions.

The particular results we report here are concerned with the damping of the bubble noise. When a bubble leaves the nozzle, the emitted sound pulse takes the form[5]

$$P_s = P_0 \exp(-\pi\delta f_0 t) \cos(2\pi f_0 t)$$

where P_s is the instantaneous radiated sound pressure, P_0 is the sound pressure amplitude and f_0 is the natural frequency. The damping constant δ has been predicted theoretically[6], and

Fig. 2 Variation of reduction in damping with additive concentration. ×, Polyox WSR 301, □, Separan AP 273.



the predicted values confirmed experimentally for nitrogen bubbles in water[7].

To check our system, we first made a comparison with previous work on gas bubbles in water[6,7]. We found that our values for damping constant and natural frequency were as expected (within ±1%). Results for the 5-mm diameter nozzle are shown in Fig. 1. This nozzle size was found to be the most satisfactory in terms of producing a good quality signal with minimum nonlinear distortion and maximum reproducibility. Thus all results presented here were taken with the 5-mm nozzle.

We obtained the time-decay curve by running the oscillograph at a chart speed of 200 cm s^{-1}. The results were analysed by dividing the amplitude at any point by the peak amplitude, and plotting on semi-logarithmic graph paper against time (measured in number of cycles) It was found that all the polymer additives reduced the damping of the emitted sound pulse to some extent, but Separan AP 30 and AP 273 increased the damping at certain concentrations. Representative results for Separan AP 273 at concentrations of 20 and 100 p.p.m. (by weight) are presented in Fig. 1, where they may be compared with the decay curve for water.

These results may be put in a more quantitative form by defining the percentage change in damping constant $100(\delta_w-\delta_p)/\delta_w$, where δ_w is the damping constant in water and δ_p the damping constant with polymer additive. This is plotted against concentration for Polyox WSR 301 and Separan AP 273 in Fig. 2. At low concentrations WSR 301 had little effect. It was only at concentrations measured in hundreds of p.p.m. (which are large compared with amounts needed for turbulent drag reduction) that one noticed appreciable reductions, ~ 10%–40%. On the other hand, Separan AP 273 did reduce the damping of the bubble noise at low additive concentrations, but the subsequent dependence of the effect on increasing concentration was rather unusual (see Fig. 2). This oscillatory form of concentration dependence was also observed in the case of Separan AP 30. Possibly this may just reflect the complexity of the bubble noise decay, involving, as it does, energy losses by acoustic radiation, thermal conduction and viscous liquid friction.

Plasma treatment of coal

Coals of various ranks have been treated in electrical arcs or plasma jets generated from argon, hydrogen, and their mixtures. In most cases the plasmas contained enough energy to heat the coal to temperatures ⩾1,000 °C. In this range of temperatures, acetylene formation is thermodynamically favoured, and an argon–hydrogen plasma has been reported to yield a maximum acetylene yield of 74% by weight of coal[1-3]. Problems are encountered with the electrical arcs because of the instability induced in the arc column by appreciable forced convection[4]. From a practical point of view methane would be the preferred product from coal gasification, and we here report on efforts to find whether a low temperature plasma favoured methane formation

We applied 50-Hz electrical discharges through 15-cm long coaxial Pyrex tubes, the annular space (1 cm wide) of which was packed with a sample of bituminous coal (76 06% C, 5.48% H, 15.33% O, 1.05% N, and 2.09% S) and degassed at room temperature. The applied voltage was 26 kV and the current through the plasma was measured to be 2 6 mA, which means the power input was ~68 W. Gas chromatographic analysis using a 1.2-m long silica gel column at 0 °C revealed that the gaseous products pumping out of the plasma zone consisted mainly of hydrogen and carbon monoxide, with small amounts of methane. A 1 2-m long alumina column at 0 °C confirmed that acetylene was not present in the products.

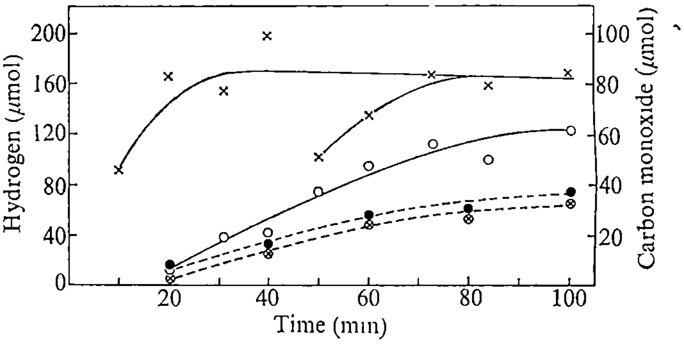

Fig 1 Hydrogen (×) and carbon monoxide (○) yields from a Siemens tube packed with bituminous coal and excited at 68 W. Solid symbols and dotted lines represent the yields from coal + 26 mmHg He.

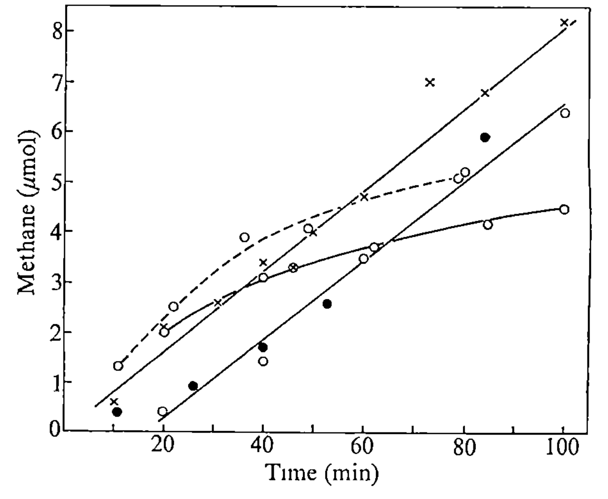
Figure 1 shows the yields of hydrogen and carbon monoxide obtained at various time intervals from a sequential operation in which coal was excited, at first alone and then in the presence of 26 mmHg of helium. The influence of the added gas was to decrease the H_2 and CO production considerably. The relatively large amounts of H_2 obtained at the short time intervals appeared to arise from an initial desorption of gases from the coal as a result of the application of the high voltage.

Figure 2 shows the methane formation as a function of the discharge period. Here again the influence of the added helium was to decrease the methane production, except in the long runs ($t>1$ h) in which the addition of helium increased the conversion of coal into methane. On the other hand, in the short runs ($t<0.5$ h) more methane was produced in experiments in which hydrogen was added to coal which had not been previously treated in a plasma. Table 1 summarises data on the conversion of the carbon in coal

Fig 2 Methane production in a Siemens tube packed with bituminous coal and excited at 68 W. ×, ○, and ⊙ for yields from coal, coal + 26 mmHg He, and coal + 26 mmHg H_2, respectively. Dotted line and solid symbols represent the yields when coal was excited at first in the presence of H_2 and then in He.



into methane The observed conversions are low for technical purposes, but this is to be expected because of the use of low frequency, low power discharges at low pressures and ordinary temperatures which allowed essentially non-pyrolytic reactions.

Table 1 Conversion of the carbon in bituminous coal into methane

Time (min)	Conversion into methane (mol per cent) Coal	Coal + He	Coal + H_2
10	12.2	—	17.6
20	12.2	5.2	21.5
40	13.9	8.0	16.2
60	9.1	11.1	11.7
80	12.0	14.8	12.3
100	11.8	14.7	10.8

The electron spin resonance spectrum of the coal subjected to plasma showed a 2.5-fold increase (~10^{18} spins per g) in the spin concentration over an untreated sample suggesting that a free radical mechanism may be involved in the gasification process

Further work using a flow-system with an argon–hydrogen mixture at atmospheric pressure is in progress.

*p*H-dependent heterosis of heavy metal-tolerant and non-tolerant hybrid of the monkey flower *Mimulus guttatus*

ALTHOUGH the toxicity of heavy metals is known to be dependent on *p*H, no studies of heavy metal tolerance in plants[1,2] have included it as a variable. We have therefore investigated the direct effect of *p*H on root growth and root number of two strains of *Mimulus guttatus*, one tolerant and the other not tolerant to heavy metals[3]. We found that the tolerant strain is also tolerant to acidic *p*H, whereas the non-tolerant operates better in more neutral *p*H. The hybrid between the two strains showed *p*H-dependent heterosis.

The strains used were Napoleon (N) and Cerrig-y-drudion (C). N is tolerant to copper[3] and is an annual population collected from a copper mine tailing at a stream edge in the Napoleon locality, Calavaras country in central California. C is sensitive to copper[3], and was originally found at the edge of a stream, 2 miles south of the village of Cerrig-y-drudion in North Wales. Seeds were germinated in soil, and clones were established from a single seed and propagated by cuttings. In the following experiment N15 and C16 were used. Although there was much variation between clones (within each population) the range of metal tolerance for N did not overlap with that of C. The F_1 was obtained by crossing ♀♀N with ♂♂C. Only one plant was crossed and different plants were obtained from its seeds.

Cuttings (one node per cutting) of uniform size were obtained from different plants about 0.5 cm below the node. Each cutting was placed in an 11-ml plastic vial filled with a solution of calcium nitrate (0.5 g l^{-1}) with varied *p*H between 2 and 9. Acid *p*H was obtained with concentrated sulphuric acid, basic *p*H with sodium hydroxide. Normal calcium nitrate solution gave *p*H 5. Ten cuttings (replicates) from different plants were used at each *p*H.

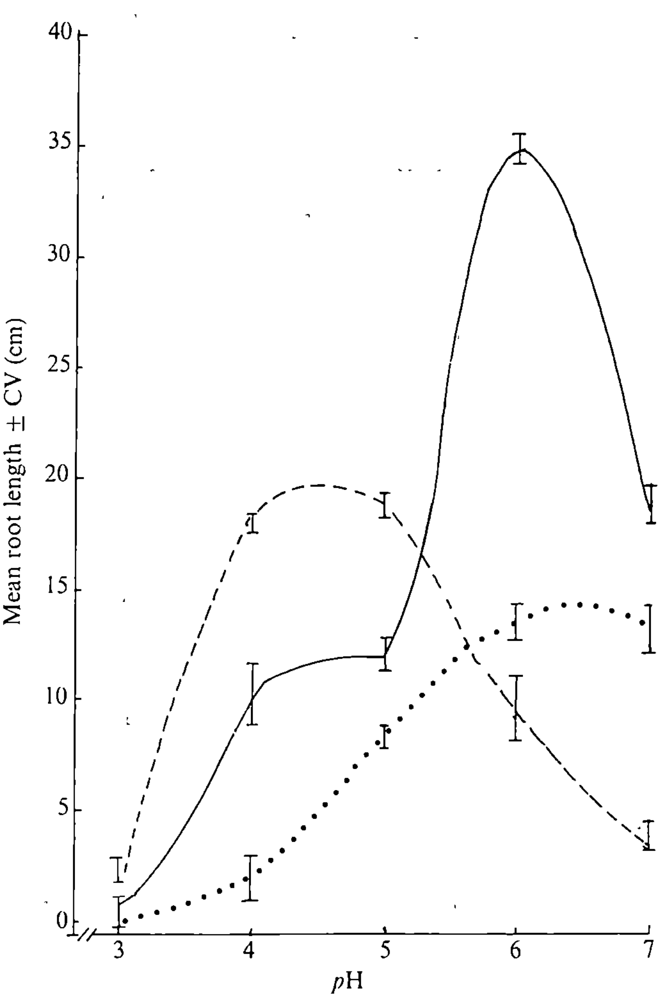

Fig. 1 Relationship between *p*H and mean root length (±coefficient of variation) – – –, N; . . , C; —, F_1.

Plastic vials were housed in wooden blocks so that light had no influence on root initiation. Each block was covered with a plastic bag to maintain humidity and placed in a growth chamber operating at a short light cycle (9 h with 25,833.6 lx), with a constant temperature of 20 °C and 55% relative humidity. The number and length of all roots from a given plant were measured. The mean of the 10 plants and coefficient of variation were calculated for each *p*H and genotype. The coefficient of variation was used to avoid any possible dependence of the variance on the mean.

The effects of different *p*H on root length are presented in Fig. 1 and Table 1. No cuttings developed any roots at *p*H 2, 8 and 9. The distribution of root growth between these levels was highly variable (Table 2). Analysis of variance using the actual data or their logarithms gave the same significant results. Using Duncan's multiple range test, it is possible to rank the effect of *p*H on root length as follows:

*p*H	3	4	7	5	6
Mean root length	0.60	10.18	12.05	13.05	19.47

where the means at *p*H 4, 7 and 5 are not significant from each other at $P = 0.05$.

The three genotypes were significantly different from each other in order C (7.52) > N (10 39) > F_1 (15.30). Analysis of variance (Table 2) and Fig. 1 indicate a significant effect of genotype on *p*H interaction. Strain N preferred the acidic

Table 1 Mean root length for each genotype at five levels of pH

Genotype	pH 3		4		5		6		7	
N	1.33*de*	(144)	18.11*a*	(37)	18.82*a*	(51)	9.74*abcde*	(136)	3.94*bcde*	(69)
C	0.00*e*	—	2.10*cde*	(98)	8.39*abcde*	(52)	13.67*ab*	(75)	13.43*abc*	(87)
F_1	0.46*e*	(172)	10.34*abcde*	(131)	11.94*abcd*	(86)	35.00	(74)	18.77*a*	(81)

Any two means with the same letter are not significantly different from each other at $P = 0.05$ by Duncan's Multiple Range test Values in parentheses are percentage of coefficients of variation.

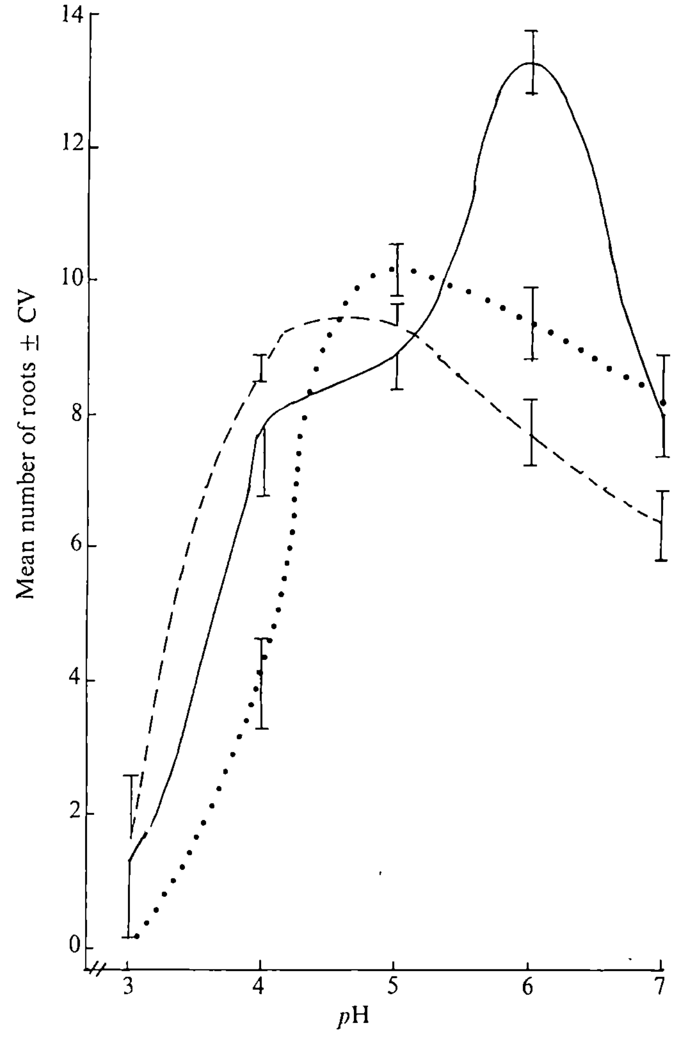

Fig. 2 Relationship between pH and mean number of roots per plant (±coefficient of variation) Symbols as in Fig 1.

solutions with a maximum peak between pH 4 and 5. Maximum root growth for strain C was in the more neutral solutions, between pH 6 and 7.

The F_1 grew better than either parent, with maximum growth at pH 6. Its performance at pH 6 and 7 indicated an overdominance in relation to its parents, whereas between pH 3 and 5 it was intermediate. This suggests two genes operating at different pH levels with different degrees of gene action. The presence of the shoulder at pH 4 substantiates this hypothesis.

Variation in pH was also found to affect number of roots per plant (Table 2). The average number of roots for the three genotypes could be ranked as follows:

pH	3	4	7	5	6
Mean number of roots	1.0	6.9	7.5	9.5	10.2

where any two adjacent numbers, excluding 1.0, are not significantly different from each other at $P = 0.05$ by Duncan's multiple range test.

These results indicate a gradual significant increase in number of roots from pH 3 to 5. The number of roots at pH 5 was not significantly different from those at pH 6, after which there was a significant decrease at pH 7. Although an analysis of variance did not reveal any effect of the genotype on the number of roots, t values for the difference between N and C at pH 4 $P = 0.01$) and N and F_1 at pH 6 ($P = 0.05$) were significant.

Phenotypic variation in length and number of roots were calculated within each genotype at each pH. These were expressed as the percentage of the coefficient of variation (Table 1). Analysis of variance on the square of such values indicated no statistical differences between genotypes or pH levels. When the genotypes were compared at each pH, however, the variability for total root growth of both F_1 and C was found to be larger than that of N at pH 4 ($F = 12.15$, $P < 0.01$ and 6.87, $P < 0.01$, respectively). Whereas at pH 6 the N strain had higher variability than both F_1 and C ($F = 3.43$, $P < 0.05$ and 3.28, $P < 0.05$, respectively).

The number of roots was less variable. The only significant differences for this trait are between F_1 or C and N at pH 4. F_1 and C variabilities are higher than that of N ($F = 23.97$, $P < 0.01$ and 11.74, $P < 0.01$ respectively) These results are similar to those obtained for root length at this pH.

It is obvious that N plants are more adapted to growing in lower pH soils than C plants. Whether this is due to direct effect of pH or due to adaptation to heavy metal ions is not known yet and needs to be investigated. (Dr Sheppard informed me that the Californian mines from which the material came are extremely acid compared with North Wales, and he has non-tolerant seeds from a very acid locality.) Undoubtedly, a study of the interaction between pH and heavy metal toxicity is of interest as indicated in Fig. 1, where for example, at pH 5 the N strain has better root growth than the C strain. This performance is reversed at pH 6 and 7 indicating pH-dependent (or conditional) toxicity for heavy metals.

Table 1 shows that pH tolerance of the F_1 is intermediate between that of its parents at pH 3–5 and is overdominant at pH 6–7. Changes in the degree of dominance due to changes in

Table 2 Analysis of variance for length of roots, number of roots, and the ratio between total growth and number of roots at different pH levels

the concentrations of heavy metals were also observed[3]. Parsons[4] argued that the hybrid advantage is maximum in extreme environments; this is substantiated by the present results at the higher *p*H levels only. These results also support the theoretical study of environment—dependent heterosis[5].

I thank P. M. Sheppard for providing the seeds and both him and R. Knight for comments on the manuscript.

Increased lead ingestion in calcium-deficient monkeys

VOLUNTARY ingestion of lead (lead pica) by children is a puzzling phenomenon. The resulting lead poisoning can lead to painful physical symptoms, mental retardation and brain damage[1-5]. Yet ingestion often persists after toxic symptoms appear if the child has access to lead[6]. We have shown that weanling rats made calcium deficient increased their voluntary ingestion of lead to levels much greater than those of control rats[7]. It was suggested that, because of the metabolic similarity of lead to calcium, ingestion of lead might relieve symptoms of calcium deficiency, attenuate the normal aversive effects of lead ingestion, and thus maintain continued ingestion. Rats, however, are not completely appropriate for an analogy to human lead ingestion because calcium metabolism differs considerably in the two organisms[8,9]. Rats seem to find lead acetate an aversive taste[7,10], whereas humans refer to it as "lead sugar" and report a sweet taste (paper presented at meeting of Midwestern Psychological Association, 1975 by R. W. Henderson and J. Dawley). Furthermore, the diet used with rats has been almost completely deficient in calcium (2 mg Ca per 100 g) producing severe symptoms of calcium deficiency, which have not been reported in humans with lead pica. If calcium deficiency leads to lead pica in humans, it must be a moderate or subclinical deficiency. We have therefore experimented with rhesus monkeys which were subjected to a moderately deficient diet providing 64% (108 mg Ca per 100 g) of their recommended daily calcium levels[11].

Four rhesus monkeys were separated from their mothers shortly after birth and maintained at the University of Wisconsin Primate Laboratory nursery. They were weaned from Similac formula to a Purina monkey chow from which the normally supplemented calcium carbonate and dicalcium phosphate had been removed, leaving 108 mg Ca per 100 g. The monkeys ingested approximately 100 g per day. Six lead ingestion tests were administered—three during deficiency and three during recovery from deficiency when the animals were feeding on normal monkey chow. Two control monkeys that had been weaned to normal chow were available for lead testing only during periods corresponding to the first two drinking tests of the deficient animals and the last drinking test during recovery. Each week the animals were weighed and blood samples were drawn to be analysed by atomic absorption spectrophotometry. Two months after calcium restoration to the deficient animals all animals were given whole body X rays.

Four concentrations of lead acetate (0.08, 0.16, 0.32, and 0.48% weight/volume) were paired with distilled water, and a pair of bottles each containing distilled water was also used. One pair of solutions was presented to an animal each day in a counterbalanced order. The relative positions of lead and distilled water bottles were alternated to control for side preferences, and each of the five pairs of solutions was presented twice. Solutions were presented at 1000 when the animals were being fed and removed at 1800. Distilled water was available overnight, but almost all fluid intake occurred during the hours of the test. For analyses the data were converted to lead acetate intake as a percentage of total intake and to the mg of lead ingested per kg of body weight.

A moderate level of calcium deficiency was produced. With calcium deficiency the body weights of the deficient

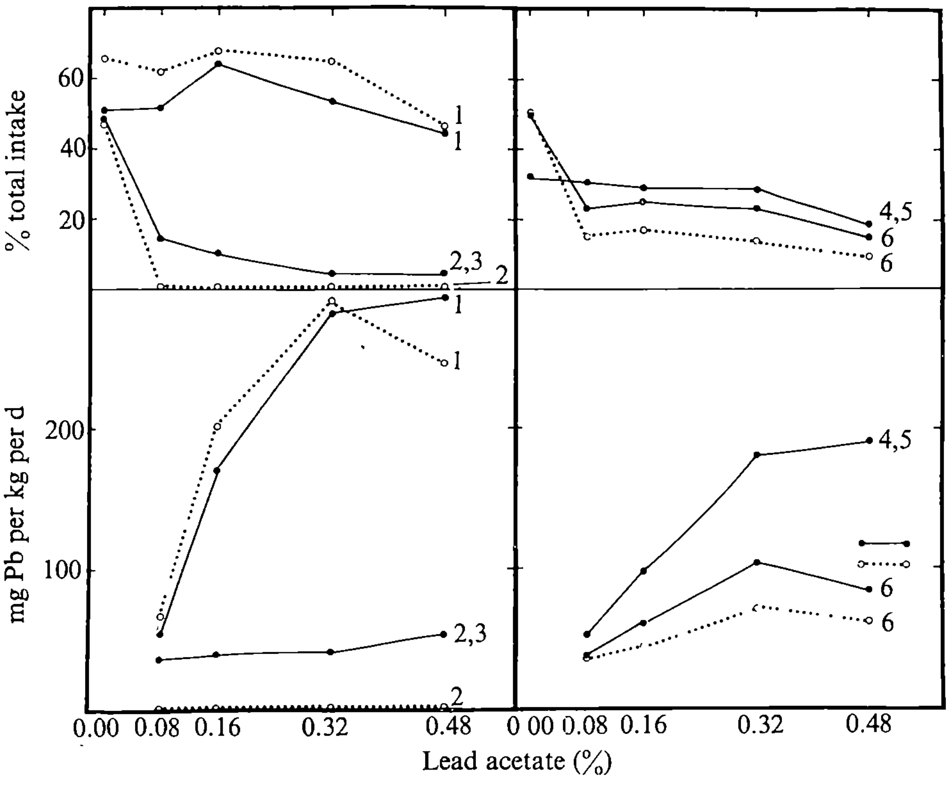

Fig. 1 Lead ingestion presented as percentage of total fluid intake (top) and mg of lead ingested per kg per day (bottom) during both calcium deficiency (left) and calcium restoration (right). Numbers at the side of each curve indicate the drinking test. Test 1 began 3 weeks after the deficient animals were weaned to calcium-deficient diet. Tests 2 and 3 began 8 weeks and 10 weeks respectively after the onset of deficiency. Tests 4 and 5 began 5 weeks and 7 weeks respectively after restoration of normal calcium, and test 6 began 24 weeks after calcium restoration. Results of tests 2 and 3 and, subsequently, tests 4 and 5 for the calcium-deficient animals did not differ so each of these pairs of tests is represented by a single mean curve. ○, Calcium deficient; ●, control.

animals decreased below those of the controls, but never went below 2 standard deviations of the mean body weights of normal monkeys at the same age at the Wisconsin Regional Primate Research Center The X rays revealed growth arrest lines in the long bones of the calcium-deficient animals presumably as a function of calcium deficiency. Because these lines were located 1.5–2.0 cm from the epiphyses, bone growth had resumed after restoration of full calcium levels and, thus, indicated that calcium deficiency had been reversed.

In the first lead drinking test both deficient and control animals ingested large amounts of lead solution at all concentrations, both in terms of percentage intake and in mg per kg of lead ingested Thus lead acetate seemed to be an initially "good-tasting" substance, in contrast to results from rats[7,10]. But after the seventh or eighth day of the first drinking test each of the control animals reduced their intake of lead solution from a mean of 273.3 ml d^{-1} to a mean of 1.4 ml d^{-1}. This low level of intake was maintained by control monkeys throughout the second lead ingestion test. Calcium-deficient animals showed some reduction in lead solution intake from the first to the second drinking test periods (mean 175.7 ml d^{-1} to 61 0 ml d^{-1}), but they maintained much higher intakes than did controls Even in a third drinking test the deficient animals maintained higher intake levels (mean 51.0 ml d^{-1}). These data are shown in the left-hand panel of Fig. 1. None of the intake measures on any of the calcium-deficient animals during either drinking tests 2 or 3 overlapped with the data of any control animal from drinking test 2 (Mann–Whitney U tests=0).

Blood lead levels were increased in both groups during lead ingestion tests (calcium-deficient mean±s.e.m.. baseline, 16.3±1.9 μg%; test 1, 228.4±25.2 μg%, test 2, 112 3±57.0 μg%; control: baseline, 20.5±1.5 μg%; test 1, 180 3±15.7 μg%; test 2, 96.2±6.2 μg%). Evaluation of the X rays of the calcium-deficient monkeys revealed radio-opaque lead deposits at the epiphyses of long bones. The animal evaluated as having the densest lead deposition was the one which had ingested the most lead; the one with the least lead deposition was the one ingesting the least lead. We did not, however, observe any overt symptoms of lead poisoning, possibly because of the temporal spacing of the lead drinking tests.

When normal monkey chow, containing five times the daily minimum recommended calcium levels for young rhesus monkeys, was given to the deficient monkeys, there was a slow, steady increase in body weight and X-ray evidence of renewed growth in long bones. But, the level of ingestion of lead acetate by the previously deficient monkeys remained high, as shown in the right hand panel of Fig. 1. Mean intakes of lead acetate were well above the intakes by control animals in both tests 2 and 6. Even 7 weeks of calcium restoration (test 5) did not eliminate these high levels of ingestion Six months after calcium restoration (test 6) the intakes of previously deficient and control animals did not differ. The increased lead ingestion of control animals relative to their test 2 levels probably reflects the several months that had passed without exposure to lead, after which the lead solutions again were the novel, "good-tasting" substances they appeared to be in test 1.

In spite of an initially positive taste valence, lead acetate was rejected quickly by normal monkeys. Calcium-deficient monkeys did not appear to recognise the presumed aversive effects of lead ingestion and continued to ingest lead at relatively high levels This increased ingestion continued until the restoration of normal calcium levels. It seems that the calcium-deficient animals were not sensitive to the negative aspects of lead ingestion, which caused complete cessation of lead ingestion in control animals This suggests that calcium-deficient animals would not be able to learn a taste aversion to a novel solution paired with the administration of lead acetate. We have shown that control rats reduced their ingestion of novel solutions paired with intragastric intubation of lead acetate, whereas calcium-deficient rats did not reduce lead-associated intake (C.T.S., unpublished) In pilot studies with rhesus monkeys we found reduced intake of lead-associated novel solution on 2 of 4 test days in control monkeys, but no reduction in monkeys that had been previously calcium deficient.

The reason why an organism should voluntarily ingest lead is partially explained. Primates seem to find lead initially "good-tasting" and ingest it in large quantities But, some post-ingestional, and presumably aversive, aspects of this continued lead ingestion eliminate subsequent lead ingestion in normal monkeys Calcium-deficient monkeys seem to be insensitive to the presumed aversive aspects of continued lead ingestion and thus do not stop ingesting lead. Given such insensitivity to aversive post-ingestional aspects of lead ingestion, calcium-deficient monkeys, even though recovered from calcium deficiency, might continue to respond to the positive taste valence of lead acetate, by continuing to ingest lead.

Since the calcium-deficient monkeys here suffered only a subclinical calcium deficiency but still ingested lead, children with lead pica may also experience only subclinical calcium deficiency. Almost all attention given to possible nutritional bases for lead pica has focused on iron deficiency, with repeated findings that iron supplementation does not reduce lead pica and that dietary iron seems to be at adequate levels[12–15]. It would be important to examine children with lead pica for evidence of subclinical calcium deficiency.

We thank Dr Mary Ann Peters for evaluating the X rays. This research was supported by grants from the USPHS and the University of Wisconsin Food Research Institute (C.T.S.).

Microvilli and cell swelling

MICROVILLI have various functions connected with an increase in surface area In the form of brush border of intestinal and renal epithelium, microvilli increase the absorptive capacity of cells. On tumour cells[1,2] they may have a role in invasiveness[3]. Their presence on cultured cells[4], which is apparently controlled by the intracellular concentration of cyclic AMP[5], increases the surface area so as to facilitate "spreading"[6] and cytokinesis[7,8] without concomitant membrane synthesis. In the latter two situations, cell volume remains constant, while the shape changes The most common situation in which the reverse occurs, that is an increase in surface area accompanying an increase in volume without a change in shape, is during cell swelling. Swelling due to entry of water is caused by (1)

Table 1 Binding of ^{131}I-con A by Lettree cells

Time of inc. (min)	Additions	Control cells	Swollen cells*
		^{131}I-bound (c.p.m.)†	
0	—	15,000	10,000
5	—	68,000	72,000
10	—	107,000	105,000
5	α-MM	8,000	9,500
0	Cold con A	8,800	7,200
5	Cold con A	54,000	67,000
10	Cold con A	63,000	61,000
5	Cold con A + α-MM	5,100	6,400

α-MM, α-methyl-D-mannoside (30 mM). Concentration of con A was 100 μg ml^{-1}.

* 1.2 M glycerol for 10 min at 4 °C, followed by 0.34% saline for 10 min at 4 °C.

† Cells at 4 °C incubated with ^{131}I-con A (375,000 c.p.m., 0.04 μg) in final volume of 0.1 ml; stopped by addition of 10 ml saline, spun and pellet assayed. Values are means of three experiments.

exposure of cells to a medium hypotonic relative to that of the cell content or (2) an increase in passive diffusion of cations[9], such that the Na/K pump cannot maintain an asymmetric intracellular/extracellular distribution. An example of (2) is afforded by the action of Sendai virus on cultured cells; passive permeability is increased[10–14] and cells swell (unpublished results of K.J.M. and C.A.P.). We show here that in both (1) and (2) the increase in surface area can be accounted for by an 'unfolding' of microvilli.

(1) Lettree cells (grown intraperitoneally in mice) were swollen by exposure to either hypotonic buffer (0.01 M sucrose, 1 mM bicarbonate, 2 mM Mg^{2+}, 2 mM Ca^{2+}) (Fig. 1*b*) or through uptake of glycerol[15] (1.2 M glycerol for 15 min at room temperature) followed by swelling in the presence of 0.25 M sucrose (Fig. 1*c*). In each case the fully swollen cells were virtually devoid of microvilli in contrast to the highly villated control cells (Fig. 1*a*). The increase in volume was from approximately 180 μm^3 to 420 μm^3 corresponding to an increase in surface area of approximately 120 μm^2. The number of microvilli on a Lettree cell (approximately 10^3 per cell; mean length 0.46 μm) increases the surface area by an average of approximately 110 μm^2. Swollen cells without microvilli bind as much ^{131}I-labelled concanavalin A (con A) as unswollen controls (Tables 1 and 2) in contrast to the effect of microvilli on agglutination by con A (Tables 1 and 2 and ref. 5). Because trypsin treatment causes rounding up of cells and a consequential increase in the number of microvilli it is possible that increased agglutinability (and perhaps stimulation of growth also[16]) of trypsin-treated cells[17,18] is partly due to an increase in the number of microvilli.

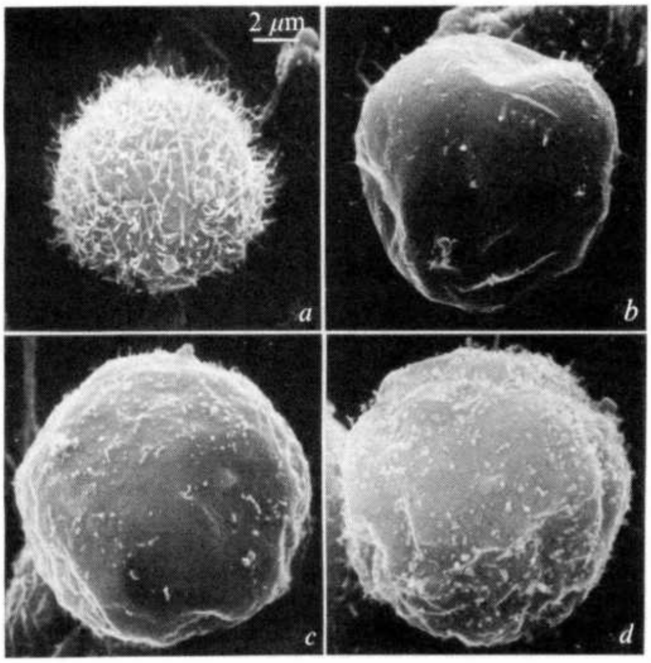

Fig. 1 Scanning electron micrographs of control Lettree cells (*a*), cells swollen in 0.01 M sucrose (*b*), glycerol-loaded cells swollen in 0.25 M sucrose (*c*) and cells after exposure to Sendai virus (*d*). Cells were fixed with glutaraldehyde at the same osmolarity as the swelling media and processed for scanning electron miscoscopy as described before[8].

(2) Lettree cells (2.6×10^4 per ml) were exposed to Sendai virus (80 haemagglutinating units per ml) at room temperature at a concentration insufficient to cause agglutination[13]. As cells increased in volume (from approximately 700 to 1,200 μm^3; Coulter size distribution mode value) most of the microvilli were lost again (Fig. 1*d*).

We conclude that the presence of microvilli enables cells rapidly to increase their volume, and hence to swell, without lysis. Mammalian erythrocytes, which are devoid of microvilli, are capable of a limited amount of swelling because in their normal shape (biconcave disk) the volume is not maximal; once a spherical shape has been adopted, lysis follows. Thus the same concentration of Sendai virus causes lysis of red cells but only swelling of villated cells. During cytolysis of cultured cells in the presence of antibody and complement, an increased cation permeability and cell swelling[19] also precedes lysis. This may explain why cells that are in the late S/G_2 phase of the cell cycle, and hence the most heavily villated[7,8], are the least sensitive to immune (or non-immune) cytolysis[20].

Table 2 Agglutination of Lettree cells by con A

Concentration of con A (μg ml^{-1})	Control cells	Swollen cells*
	Agglutination index†	
500	+++++	+
250	+++++	++
150	+++++	+++
100	++++	++
50	++++	++
0	+	+

* As in Table 1 but at room temperature.

†Cells at room temperature mixed with con A and agglutination assessed microscopically: +++++, <10% free cells; ++++, 10–30% free cells; +++, 30–50% free cells; ++, 50–70% free cells; +, >70% free cells.

Since swelling caused by treatment with hypotonic media or with Sendai virus is readily exploitable, the implication that the increase in volume results from an unfolding of microvilli should prove useful in elucidating the role of microvilli (and cyclic nucleotides) in more complex phenomena such as cytokinesis and other situations involving the cell surface.

Ionic mechanism of the H^+ pump in a snail neurone

THE observed values of *p*H inside nerve and muscle cells are too high to be explained by a passive distribution of H^+ across the cell membrane[1–4]. Thus there is believed to be a system, provisionally named a H^+ or proton pump, which transports H^+ out of, or OH^- or HCO_3^- into the cell. In spite of its importance, little is known about this system, perhaps because it cannot easily be studied using radioisotopes, the use of which has yielded much information about the far better known Na pump. One way the H^+ pump can be investigated is by following intracellular *p*H (pH_i) with a *p*H-sensitive microelectrode: because a similar Na^+-sensitive microelectrode can be used to study the Na pump, it is also possible to compare the two pumps in the same preparation using essentially the same methods. Thus the recessed-tip type of *p*H-sensitive[3] or Na^+-sensitive[5] microelectrode can be used to record pH_i or intracellular Na^+ ($[Na^+]_i$) in cells, such as snail neurones, which are tough enough to permit intracellular iontophoretic injections of acid or Na salts. I report here experiments in which the mechanism of the H^+ pump has been investigated by comparing the response of pH_i to HCl injection with the response of $[Na^+]_i$ to NaCl injection.

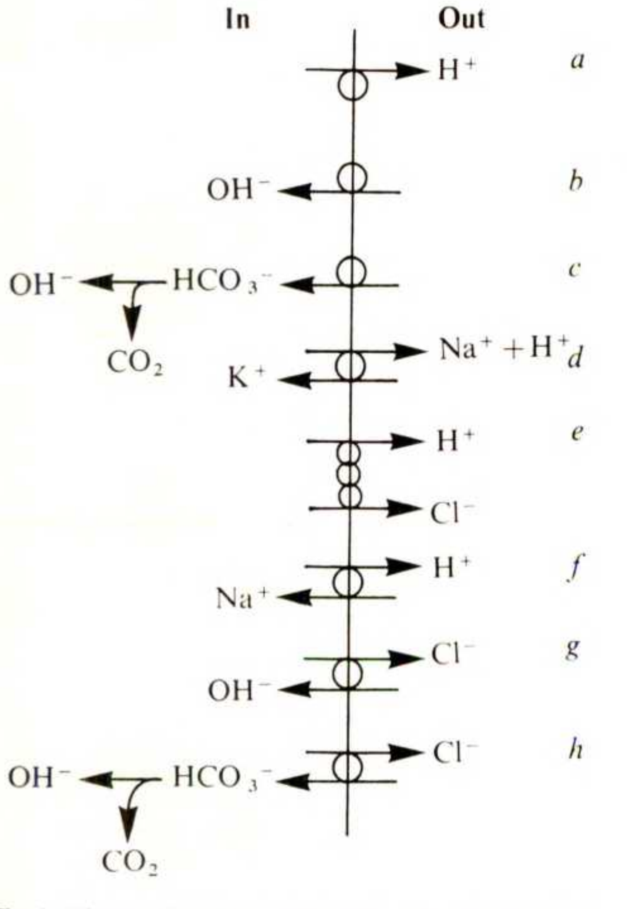

Fig. 1 Diagram showing possible mechanisms for the H^+ or proton pump in cell membranes, excluding any indication of the energy source. *a*, Simple uncoupled H^+ pump; *b*, hydroxyl ion pump; *c*, bicarbonate pump (inside the cell the bicarbonate would give rise to OH^- and CO_2, the latter being freely diffusible across the cell membrane); *d*, the Na or Na–K pump extruding H^+ as well as Na^+; *e*, a loosely coupled HCl pump; *f*, downhill Na^+ influx coupled to H^+ extrusion; *g*, chloride–hydroxyl ion exchange; *h*, chloride–bicarbonate ion exchange.

Various mechanisms have been proposed[6,7] to explain the mechanism of the H^+ pumps involved in both pH_i control and acid secretion by the stomach. Some of these mechanisms are outlined in Fig. 1. Schemes *a–d* involve the net transfer of charge across the cell membrane, and would thus be electrogenic[8], while *f–h* would be electrically neutral. The linked extrusion of H^+ and Cl^- shown in *e* could be electrogenic or neutral. Scheme *d* represents the well known Na pump (or more accurately, the Na–K pump) which might extrude H^+ rather than Na^+ (ref. 9). But evidence from experiments on the effects of ouabain, a specific inhibitor of the Na pump, on muscle pH_i does not support this idea[10]. For acid secretion by the stomach, most investigators apparently favour schemes *e* or *h*. The latter has been studied in great detail in red blood cells, where it is known as the "chloride shift", and is an important mechanism in CO_2 carriage by the blood. This anion-exchange in red blood cells is blocked by amino reactive agents[11] such as 4,4′-diisothiocyanostilbene-2,2′-disulphonic acid (DIDS). I have therefore tested the effects of both DIDS and ouabain on the Na and H^+ pumps in the snail.

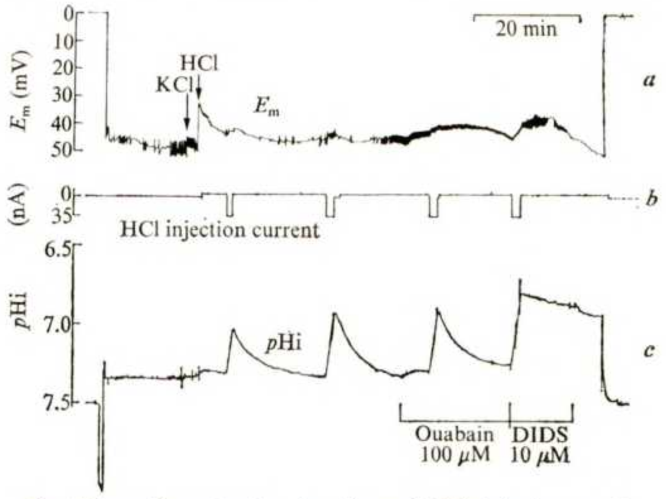

Fig. 2 Recordings showing the effects of HCl injection on E_m and intracellular *p*H (pH_i) of a snail neurone, and the response to external ouabain and DIDS. *a*, Potential between the E_m microelectrode and a reference electrode in the bath; *b*, iontophoretic injection current; *c*, potential between the E_m and *p*H microelectrodes. The voltage scale was the same for *a* and *c*. The *p*H microelectrode was inserted first, then the KCl-filled E_m microelectrode. After about 15 min, the two current-passing electrodes were inserted, and a 5-nA backing current was switched on between them to minimise H^+ leakage from the HCl microelectrodes. HCl injections were made by reversing the iontophoretic current and increasing it to 35 nA for 1 min (first injection) or 90 s (other injections). After the pH_i had recovered from the second injection, ouabain was applied in the superfusate, and after the third injection DIDS was applied, as indicated. Finally the electrodes were withdrawn from the cell.

The experiments were done on the largest neurone at the rear of the right pallial ganglion of the common snail, *Helix aspersa*, as described before[12]. The exposed suboesophageal ganglia were superfused with a continuously flowing snail Ringer (4 mM KCl, 80 mM NaCl, 7 mM $CaCl_2$, 5 mM $MgCl_2$, 22 mM $NaHCO_3$, 0.1 mM Na_2HPO_4/NaH_2PO_4 (*p*H 7.5), equilibrated with 2.5% CO_2 and 97.5%

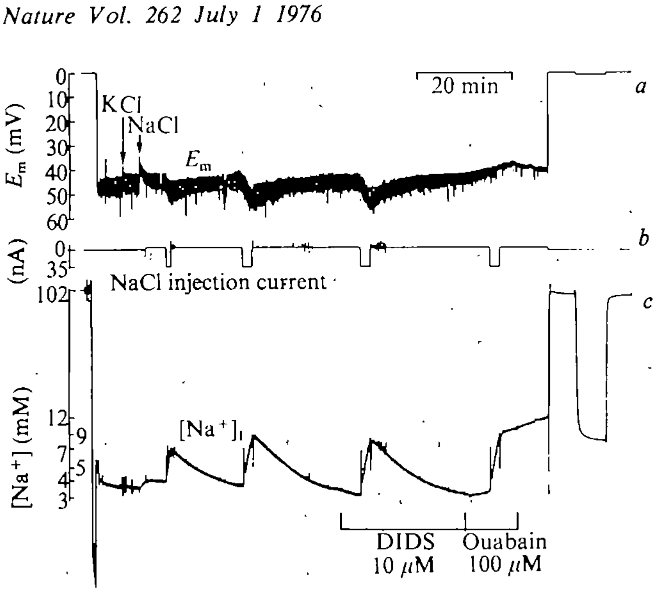

Fig. 3 The effects of NaCl injection on the E_m and $[Na^+]_i$ of a snail neurone, and the response to external DIDS and ouabain. Procedure was as in Fig. 2, except that the duration of the second, third and fourth injections was 2 min, the inhibitors were applied in reverse order and after withdrawal from the cell the electrodes were exposed to a Ringer with 9 mM Na.

O_2). The neurone was penetrated by four microelectrodes: one to measure membrane potential (E_m), one to measure Na^+_i or pH_i, and two for iontophoretic injection, of which one was filled with KCl and the other with NaCl or HCl.

The effects of ouabain and DIDS on the H^+ pump are shown in Fig. 2. During four injections of HCl the pH_i fell. After the first three injections it returned to the pre-injection level during 15 min. The application of the ouabain-containing Ringer caused a small fall in pH_i, presumably because of a slightly lower CO_2 level, but clearly did not block the pH_i recovery. But DIDS, applied at the beginning of the fourth injection, equally clearly did inhibit the pH_i recovery. Other experiments showed that the H^+ pump was very sensitive, 50% inhibition required only about 1 μm DIDS. Its analogue 4-acetamide-4′-isothiocyano-stilbene-2.2′-disulphonic acid (SITS) had the same effect.

Figure 2 also shows that the H^+ pump is not electrogenic: there were only small changes in E_m during pH_i recovery after the HCl injections. This rules out the mechanisms shown in Fig. 1*a–d*. In contrast, Fig. 3 shows the characteristic E_m increase associated with the electrogenic Na pump. The quantities of NaCl and HCl injected were similar; they were injected into the same cell (in different snail brains) and caused similar changes in the ion equilibrium potentials. Figure 3 also shows that DIDS had no effect on the Na pump while, as expected, ouabain blocked it completely.

In some ways the pH_i and $[Na^+]_i$ responses to HCl or NaCl injection were remarkably similar. The recovery of pH_i was faster, but both recoveries were exponential and repeatable. The effects of ouabain and DIDS were, however, completely different. This clearly rules out any direct connection between the Na and H^+ pumps, as in Fig. 1*d*.

Since DIDS and SITS are both well established inhibitors of anion exchange in red blood cells, and SITS also blocks the anion-dependent part of the short-circuit current across the turtle bladder[13], it is tempting to conclude that the H^+ pump in snail neurones is a Cl^-–HCO_3^- exchange system, as in Fig. 1*h*. The finding that the H^+ pump in both squid giant axons[14] and snail neurones[12] is stimulated by CO_2 and HCO_3^- certainly supports this mechanism.

The source of energy for what would be an 'uphill' movement of HCO_3^- into the cell is difficult to identify. The Cl^- equilibrium potential (E_{Cl}) in the neurone studied is normally close to or more negative than E_m, so Cl^- extrusion would also normally be uphill[15]. In my experiments E_{Cl} would have been greatly reduced by Cl^- injection, but in other experiments the speed of pH_i recovery was not affected by internal Cl^- levels. It is possible that the anion leaving the cell is not Cl^-, but it is hard to suggest an alternative. It is well established that the Na pump is driven by ATP, but preliminary experiments with metabolic inhibitors suggest that ATP may not be the energy source for the H^+ pump in snail neurones. For example, the uncoupling agent carbonyl cyanide *m*-chlorophenyl hydrazone (CC*m*P) blocks the Na pump at levels which have little effect on the H^+ pump. On the other hand, Boron and De Weer[14] found that 2 mM cyanide inhibited the H^+ pump in squid giant axons. Perhaps the H^+ pump can tolerate a much lower ATP : ADP ratio than the Na pump.

In conclusion, the results reported here show that there is no connection between the Na and H^+ pumps in snail neurones, and suggest that the H^+ pump is an electroneutral anion-exchange system in which the inward transport of HCO_3^- is coupled to the outward transport of other anions, presumably Cl^-.

I thank Professor H. Passow and Dr H. Fasold for DIDS, Dr Z. Kometiani for helpful discussions and Drs E. Mills and M. Purves for reading the manuscript.

Note added in proof: Recent experiments of mine on the snail neurone H^+ pump suggest that there may be some Na^+-H^+ exchange as well as the anion exchange described above. In mammalian cardiac and skeletal muscle SITS has no effect on the H^+ pump (D. Ellis and C. C. Aickin, personal communication), suggesting that the pump mechanism in muscle does not involve anion exchange.

Role of axoplasmic transport in neurotrophic regulation of muscle end plate acetylcholinesterase

THE mechanism underlying neural control of skeletal muscle acetylcholinesterase (AChE) is not fully understood[1]. The experimental evidence points to acetylcholine (ACh)[2] and nerve-evoked muscle activity[3] as the "trophic" mediators, but neither is sufficient to account for the entire effect of innervation on muscle[4]. It remains to be seen whether factors such as cell-to-cell contact, and/or some regulatory substance(s) released by motor nerves also contribute to the regulation of AChE activity. In turn, the regulatory substance(s) might be conveyed by axoplasmic transport, for blockage of this process causes denervation-like changes without disturbing neurotransmitter release or the consequent muscle contractile activity[5]. We report here a reversible change in the activity of endplate AChE that can be ascribed to a temporary interruption of axoplasmic transport.

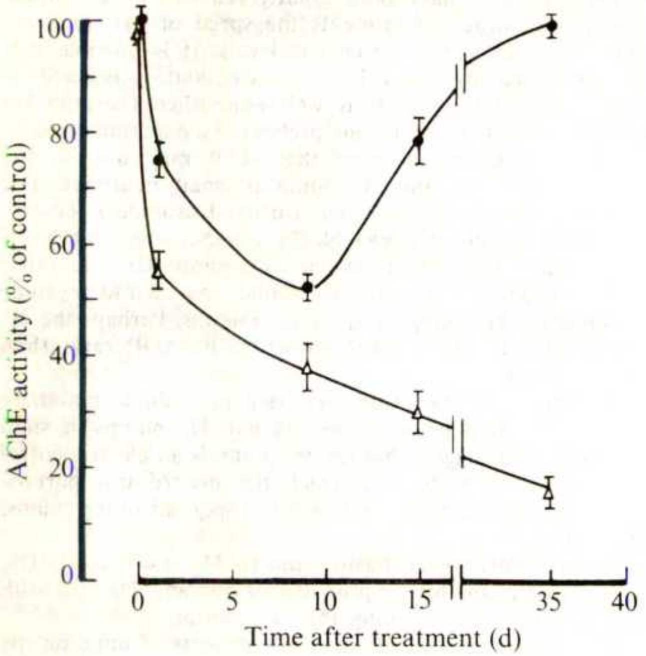

Fig. 1 Effect of axoplasmic transport blockage (●) and denervation (△) on AChE activity, in cat geniohyoid muscle. Muscle regions containing endplates were homogenised 1/50 (w/v) in ice-cold NaCl–Triton buffer, *p*H 7.3 (1 M NaCl, 0.1% Triton X-100, 0.05 M Tris–HCl, 0.2 mM EDTA). AChE activity as reported here is that portion of the homogenate-dependent ACh hydrolysis that is sensitive to 5 μM BW 284 C51 dibromide. Activity was measured by a radiochemical procedure in which release of ^{3}H-acetate from ^{3}H-ACh iodide (New England Nuclear, 50 mCi mmol^{-1}) was quantified by ion-exchange chromatography and scintillation spectrometry[8]. One unit of AChE activity is defined as 1 μmol ^{3}H-acetate formed per min. For each assay the final non-collagenous protein concentration[15] was 2–3 mg per ml of homogenate. At the concentrations used, Triton X-100 did not interfere with the AChE assay. Because of changes in the protein content of muscles undergoing atrophy and hypertrophy, the AChE activity could not be correlated with either the initial wet weight, or the particulate protein content of the individual muscle[16], therefore, the results are expressed by comparison of the treated side with the contralateral innervated muscle (control). Each sample was assayed at three concentrations and the activities obtained were proportional to the sample concentration. Each point represents the mean ± s.e. of three experiments.

Experiments were performed on adult cats, anaesthetised with sodium pentobarbital (36 mg kg^{-1}). Both hypoglossal nerves were injected under the epineurium (experimental: 5 μl of saline, 10 mM colchicine; control: 5 μl of saline), 5 mm distal to the emergence point of the lateral branch innervating the geniohyoid muscle. Thus surgical damage was avoided since the drug reached the nerve fibres under study only by diffusion[6]. In similar experiments, one of the nerves was transected while the contralateral was left intact. At various times after the operation, the geniohyoid muscles were exposed in order to record their electrical activity and contractile properties. Subsequently they were removed and regions containing most of the endplates (80% of the AChE released by collagenase treatment[7] came from these regions) were used to assay AChE[8]. Consistent with a previous report[6], 6–30 d after injection of colchicine, a drug known to interfere with axoplasmic transport[9], the muscles became hypersensitive to ACh and displayed fibrillation. Nerve conduction and the effective neuromuscular transmission were unaltered. These results were obtained through blockage of axoplasmic transport as induced by the direct action of colchicine on the motor nerve[6,10]. When applied locally under the epineurium, the drug does not reach the muscle cells. Further, when applied topically on to the muscle at concentrations that interrupt axoplasmic transport, the drug provoked none of the alterations observed when it was applied to the nerve. Thus colchicine may not necessarily cause denervation-like changes by acting on the muscle membrane[11].

Figure 1 illustrates that, after treatment with colchicine, the activity of endplate AChE gradually decreased (days 1–3), reached its lowest level (days 8–10) and returned to control values (days 25–30). In as much as colchicine blocks axoplasmic transport[10], the normal operation of this process seems to be essential for the neurotrophic regulation of endplate AChE activity. Our experiments are insufficient to elucidate the basic mechanism of this dependence. Nevertheless, we can assume that axoplasmic transport supplies some trophic factor to the postneural cell. This rationale is reinforced by findings which suggest the existence of a neurogenic diffusible substance affecting AChE activity of muscle in organ culture[12].

In contrast to the reversible effect of treatment with colchicine, denervation causes a greater enzymatic decay which persists for at least 35 d (Fig. 1). This quantitative difference can be ascribed to: (1) a partial blockage of axoplasmic transport, and/or (2) the regulatory action of other factors, such as muscle contractile activity or ACh itself. Muscle activity has been claimed to be the major factor involved in the control of chick muscle AChE[3], but in mammalian muscles it has no such influence[13]. In turn, the role of ACh in AChE regulation is supported by results obtained with botulinum toxin which—apart from inhibiting ACh release—may block the liberation of other neurogenic substances[2,14]. In view of our results, we conclude that axoplasmic transport is the most important mediator in the trans-synaptic regulation of skeletal muscle endplate AChE activity.

Three-step yielding of load-clamped mammalian cardiac muscle

FROM mechanical transients of active skeletal muscle in response to length[1] or load[2,3] perturbations some aspects of the kinetics of crossbridge interactions between actin and myosin filaments have been studied. The analysis of tension transients following rapid length steps has indicated that crossbridges may be the major site of series compliance in active skeletal muscle[1,4,5]. The use of load steps[2,6] instead of length steps has the advantage that any series compliance does not change in length after the step. Yet, in the rapid skeletal muscle load steps cannot be applied sufficiently fast to distinguish the very early events in view of their possible relation to crossbridge interactions[5]. We have analysed length transients after small step increases of load, which did not exceed the isometric tension, during isotonic shortening of afterloaded twitch and tetanic contractions of slow mammalian cardiac muscle at a low temperature, that is cat papillary muscle at 19 °C. Our main conclusion was that motion of attached crossbridges is confined to near 0.80 (twitch) to 1.02 (tetanus) % of total muscle length.

Figure 1 illustrates the effects of a sudden increase of load during isotonic shortening of an afterloaded twitch. There were three distinct phases in the yielding of the muscle during the load clamp. An initial rapid lengthening (phase 1) accompanied the load step itself. The subsequent constant load resulted in a slower lengthening (phase 2) followed by a high velocity lengthening (phase 3). The amplitude of phase 1 varied with the magnitude of the load step (Fig. 1*d*), but was the same for a given load regardless of the time of the step (Fig. 1*c*). From the length changes during phase 1 for various loading and unloading steps at any given time, a single uninterrupted force–extension curve was obtained. The length change of phase 2 occurred at constant speed and varied with the magnitude of the imposed load. But analysis of load clamps at various instants before peak shortening (Fig. 1*c*), of various magnitudes (Fig. 1*d*) and at various isotonic loading conditions before length change, of phase 2 and the magnitude and speed of phase 2, measured as the length between the end of phase 1 and the length where phase 2 deviated from the tangent to phase 2, did not exceed a particular maximal value. That particular maximal value averaged 0.80±0.05 (s.e.m.; $n=14$ muscles) % of l_{max}. Moderate under- or overdamping of the load step made the transition from phase 1 to 2 respectively slightly more or less distinct than at critical damping but without altering the magnitude and speed of phase 2. The level of constant speed, but not the maximal length change, of phase 2 and the magnitude and speed of phase 3 seemed to be time dependent. To measure the contribution of changing activation in twitch contractions, we performed further experiments on muscles tetanised by trains of high-intensity electrical stimuli at [Ca^{2+}] 10 mM and caffeine 10 mM in the bathing solution[11].

Figure 2 (upper) shows two superimposed load clamps during steady shortening of an afterloaded tetanus. Again, three distinct lengthening phases were observed. Instantaneous phase 1 varied with the amplitude of the load step. The magnitude of the lengthening during phase 2 was respectively 0.99 and 0.96% for the load clamps *a* and *b*. The mean maximal value was 1.02±0.06 (s.e.m.; $n=10$ muscles) % of l_{max}. Transition to phase 3 occurred earlier in time and at a higher speed as the amplitude of the load step was increased. During a sustained tetanus, phase 3 was followed by a slow recovery (phase 4) without oscillations.

From force–extension analysis, phase 1 was shown to reflect instantaneous undamped series compliance accompanying the load step itself. The nature of series compliance in cardiac muscle is presumably more complex than in skeletal muscle[1,5,6], that is crossbridge links between actin and myosin filaments[1,4], branching[12], spiral arrangement of the fibres[13], shearing through Z-lines and intercalated disks[14], and damage of tissue adjacent to the clip[15]. We largely bypassed these problems by the conditions of isotonic loading at heavy afterloads, allowing for homogeneous temporal and spatial distribution of force and nearly maximal extension of all non-crossbridge sources of series elasticity before the clamp. Nevertheless, because of the unpredictable relative contribution of crossbridge and extra-crossbridge compliance, phase 1 was not analysed further.

Closer attention was focused on the delayed lengthening of the muscle during the steady-state phase of the load clamp when series elastic elements do not change in length. Analysis of length responses to load clamps in steady-state isotonic conditions also precluded the importance of an unpredictable relation that exists in isometric contractions between sarcomere length and the external length of the preparation and that results from the large amount of connective tissue with uneven distribution of forces[16]. Relating overall muscle length to sarcomere length was an assumption underlying the following discussion, and fluctuations of myofilaments about their mean positions within sarcomeres due to fluctuating forces along myofibrils[17] were omitted. Since sarcomere lengths at l_{max} obtained from living cardiac muscle[18] were reported to average 2.23 μm (ref. 19) and 2.30 μm (ref. 20) an assumed sarcomere length of 2.25 μm at l_{max} enables phase 2 to be expressed as an average length change of 9.0 nm per half sarcomere for twitch contractions. Accounting for internal shortening of about 5% of l_{max} resulting from extension of series elastic elements during the isometric phase of the afterloaded contraction[18], yielded a value of 8.6 nm per half sarcomere. Similar calculations for tetanised contractions provided a phase 2

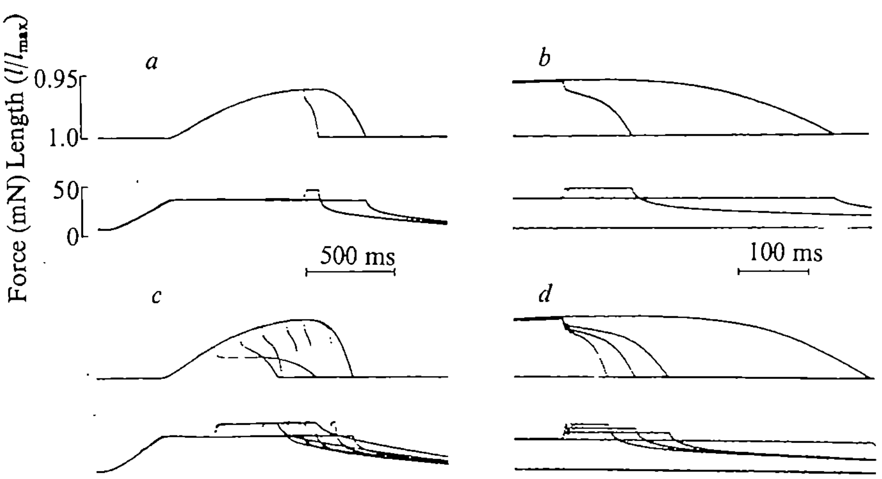

Fig. 1 Length responses of cardiac muscle to sudden increases in load in afterloaded twitch at 19 °C. Although 3-step yielding during load clamps was also observed at higher temperatures (29 °C), the time resolution of the phase 2 lengthening was less satisfactory for further analysis. Length and force gains were the same for all panels. *a*, Slow sweep length and force tracing of load clamp at a time near peak shortening of afterloaded isotonic twitch; control afterloaded contraction is also shown; preload was set at l_{max}, while afterload was augmented to near 70% of isometric conditions so that subsequent isotonic shortening had not proceeded below $0.95 l_{max}$ before the load clamp. *b*, Fast sweep tracings of contractions illustrated in *a*; fast sweep begins just before load clamp is applied; lengthening has three distinct phases. *c*, Slow sweep tracings of load clamps at various times during a twitch; fourth clamp from left is the same as in *a*. *d*, Fast sweep tracings of load clamps of various magnitudes at a given time during a twitch; middle clamp is the same as in *b*. All experiments were performed at the initial muscle length l_{max}, that is the length at which active force development of an isometric twitch was maximal. The experimental protocol has been extensively discussed previously[7-9]. Suitable muscles were selected on the basis of their ratio of resting to total force at l_{max} (refs. 7-9), the mean ratio being 0.11±0.01 (s.e.m.; n = 17 muscles) at 29 °C and 12 per min. To account for the long term memory of cardiac muscle for loading in preceding contractions[10], all test contractions were separated by a series of at least 6 equally loaded standardised contractions.

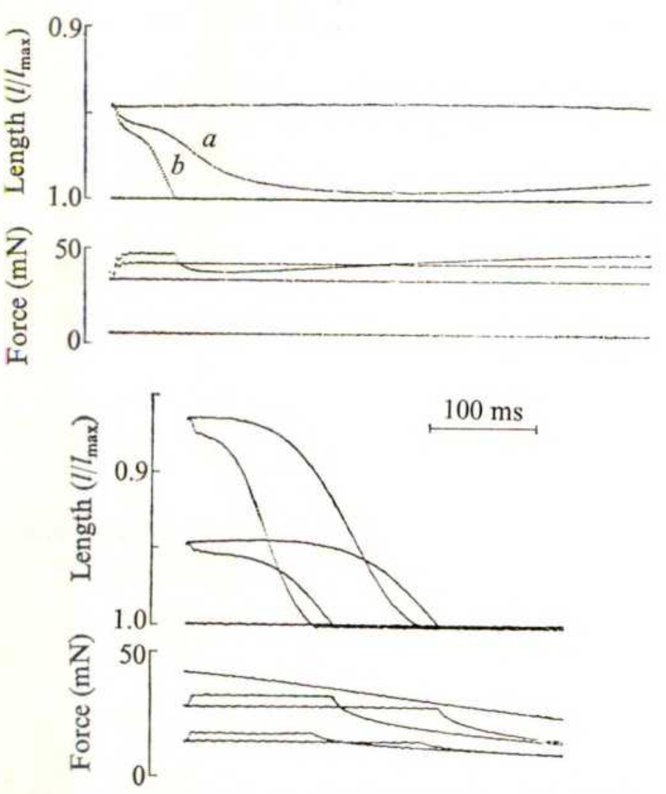

Fig. 2 Upper panel (tetanus): length responses of tetanised cardiac muscle to sudden increases in load (fast sweep); two clamps with different loads were applied during steady shortening of heavily afterloaded tetanus; isotonic shortening had proceeded to about 0.94 l_{max} before the clamps; control tetanic contraction is also shown. Tetanic stimulation train was sustained along the whole duration of the record. Lower panel (twitch): fast sweep record of load clamp before and after halving afterload and amplitude of load step during twitch at 19 °C. Part of the force tracing of an isometric twitch contraction is also shown.

length change of 10.9 nm per half sarcomere. These values are of the same order of magnitude as the extent of motion ascribed to crossbridges in skeletal muscle[1-5]. We therefore propose that during phase 2 attached crossbridges are forced to rotate back to their first point of attachment, as has been suggested for skeletal muscle[5,21]. To test the connection of the delayed phase 2 lengthening distance with the extent of a crossbridge stroke, both afterload and load-step magnitude were halved with respect to the control load clamp experiment (Fig. 2, lower). If it is assumed that the number of attached crossbridges is proportionally altered, the extent of phase 2 lengthening should nevertheless be the same in both conditions. The magnitude of phase 2 was not altered indeed ($n=11$ muscles; $P>0.5$) and thus reflects the full range of back rotation of attached crossbridges.

Rapid phase 3 lengthening might then result from forcible breakage of attached crossbridges. The fall of isometric force following completion of phase 3 in afterloaded tetanus was always clearly apparent, even in experiments where steady tetanic shortening at the time of the clamp had not proceeded to lengths below 0.98–0.99l_{max}. This suggested that the load step itself or the concomitant lengthening might have detached some load bearing crossbridges and that crossbridges in a less favourable position of attachment could have detached all along the clamp including during phases 1 and 2. Analysis of clamps, which after durations of 2–100 ms were reversed to the original load during phases 1 or 2 in twitch and tetanus, yielded the same conclusion in showing incomplete or delayed recovery to the original shortening tracing. Such crossbridge events could possibly account for the effect of deactivation caused by motion in heart muscle[22]. Although some crossbridge reattachment might have occurred from the onset of the load clamp[5], the far delayed recovery phase 4 during tetanus would predict reattaching during phases 1, 2 and 3 proceeding at a relatively much slower rate than detaching.

Another possible explanation is that of a lengthening pattern following the load step but not uniform with respect to time in all segments along the length of the preparation during a twitch, with lengthening in some portions of the fibre and actual shortening in others[1,6,23]. Phase 2 could then result from the delayed relaxation of those sarcomeres exhibiting the longest duration of mechanical activity. The three step yielding during tetanus under homogeneous temporal and spatial activation rules out the contribution of such longitudinal inhomogeneity of the duration of activity.

In conclusion, using the slow contraction mode of mammalian cardiac muscle at low temperature, we have analysed the delayed lengthening after load perturbations and we propose that in cardiac muscle, as in skeletal muscle[1], force is generated by the total number of bridges attached in parallel between myosin and actin, pivoting about their attachment with a turnover of 8.6–10.9 nm per half sarcomere, thus producing a force by extending the more compliant portion of the bridges by the same amount.

New elastic protein from muscle

IT has long been assumed that an elastic component other than extracellular collagen fibres is present in muscle fibres to explain their elastic properties, especially during passive stretch[1,2] The presence of such an elastic component has been demonstrated in skinned fibres of frog skeletal muscle[3,4]. Furthermore, it has been observed that myofibrils after the removal of myosin are reversibly extended, indicating their structural continuity[5]. The chemical entity responsible for the intracellular elasticity of muscle has, however, remained obscure. When rabbit myofibrils were thoroughly extracted with salt solutions such as 0.6 M KI, it was noticed that remaining Z lines still maintained their continuity, although nothing could be seen between the adjacent Z lines under a phase microscope (compare ref. 6). Starting from this observation, we have been able to isolate an elastic protein from myofibrils which is clearly distinguishable from elastin or collagen.

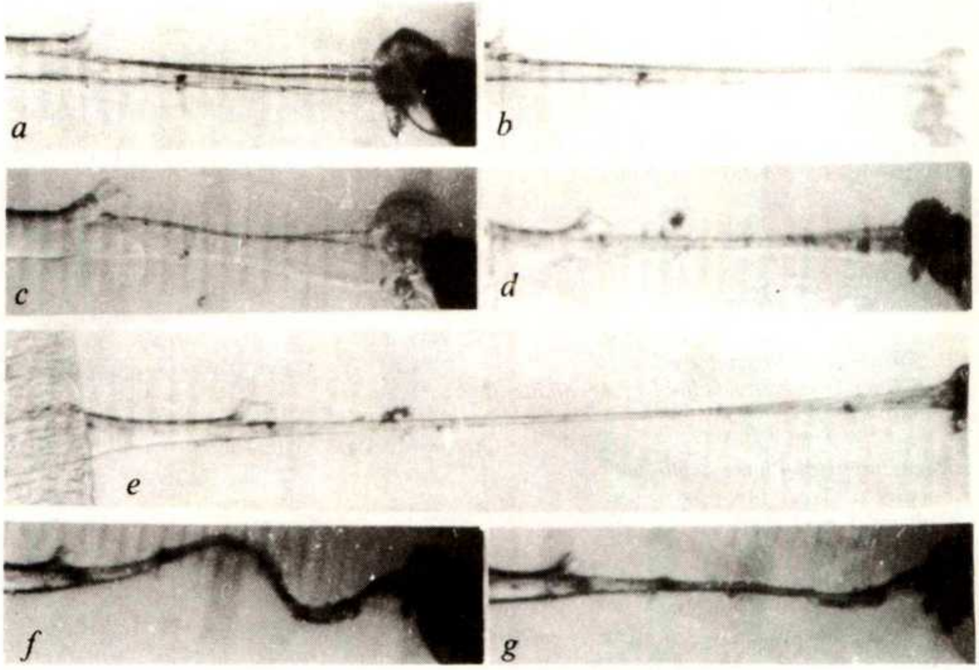

Fig. 1 Passive stretch of 'ghost' skinned fibres. *a*, Skinned fibres of sartorius muscle of the bullfrog in liquid paraffin, 20° C; *b*, stretched skinned fibres; *c*, skinned fibres treated with an alkaline solution (1 M KI, 0.1 M $Na_2S_2O_3$, *p*H 11.5); *d*, after 20 h in the alkaline solution, fibres were washed with Endo's solution (107 mM K-methanesulphonate, 4 mM $MgSO_4$, 4 mM ATP, 2 mM EGTA, 20 mM Tris-maleate, *p*H 6.8); *e*, the same, stretched; *f*, the same immediately after release; *g*, the same, 1 s after release.

Myofibrils were prepared from rabbit psoas muscle according to Perry and Grey[7]. It turned out, however, that the myofibrils contained broken muscle fibre fragments together with free myofibrils and it was necessary to separate them by sucrose density gradient centrifugation (see ref. 8). Light and electron microscopic examinations revealed that myofibrils were free of fibre fragments and connective tissues and fibre fragments were contaminated a little by free myofibrils. Both preparations were exhaustively extracted with Hasselbach–Schneider solution and water, and then with 0.6 M KI (ref. 9). After the residues were extracted with 1 N acetic acid overnight, they were washed with water and extracted in 0.1 N NaOH for several hours at room temperature. The suspension was centrifuged to remove a yellowish supernatant. After neutralisation the residue was treated with hot phenol to remove some glycoproteins. The phenol-insoluble material was washed with water. Approximately 50 mg of protein was obtained from pure myofibrils (1 g protein). A somewhat larger amount was present in fibre fragments (70 mg per 1 g protein). The final product was not soluble in 1% sodium dodecyl sulphate, and therefore, no protein band was detected in a gel electrophoresis.

As the phenol-treated residue was washed with water, the material became adhesive and finally formed a lump. It was possible to prepare a thread of the protein by cutting out the lump. Stretched to 130% of the initial length, the thread was at a tension of as much as 2 kg cm^{-2}. Examination of the tension–length relationship at different temperatures showed that the thread had rubber-like elasticity (compare ref. 4). The Young's elastic modulus was about 4×10^6 dyne cm^{-2}, a magnitude similar to that of unvulcanised rubber. The protein is therefore an elastic protein.

The amino acid composition of the muscle elastic protein is given in Table 1. The proteins from myofibrils and fibre fragments were similar to each other in amino acid composition. It is of some interest that the glycine content is much smaller than that of collagen, elastin[10] or resilin[11], which are well known as elastic proteins (see ref. 12). The muscle elastic protein contained a small amount of hydroxyproline, which is abundant in collagen or elastin (cf. ref. 12). The amino acid composition is similar to that of non-collagenous reticulin, an extracellular glycoprotein of the basement membranes[13], which is shown to be present in the endomysium of muscle[14]. There are distinct differences between the two proteins in hydroxyproline, cystine/2 and leucine content. The reticulin is soluble in 0.05 N NaOH[13]. Furthermore, the elastic protein from myofibrils and fibre fragments contained only 0.5–1.0% of neutral sugars in comparison with 4% of reticulin[13].

The localisation of the elastic protein in myofibrils is still obscure, but it seems that it is responsible for their continuity. After extraction of a skinned fibre of frog muscle with an alkaline solution of *p*H 11.5, the elastic structure seemed to remain intact, although other structures visible under the microscope disappeared. It developed tension when stretched and behaved as an elastic body (Fig. 1). Treatment with 0.1 N NaOH resulted in a considerable decrease in tension generation, suggesting that the elastic properties had been damaged.

The muscle elastic protein makes at least some contribution to the intracellular elasticity of muscle fibre. The relationship between the elastic protein and reticulin or collagen at the myotendinous junction is of much interest from the viewpoint of tension transmission.

Table 1 Amino acid composition of elastic protein from pure myofibrils and fibre fragments of rabbit psoas muscle*

	Pure myofibrils	Fibre fragments
Hypro	7	12
Asp	95	92
Thr	61	59
Ser	61	60
Glu	130	128
Pro	63	65

Down's syndrome and related abnormalities in an area of high background radiation in coastal Kerala

BOTH point mutations and structural aberrations of chromosomes are induced by ionising radiations, causing genetic variation and abnormalities in man and other organisms. The mutagenic effects are dose dependent and in *Drosophila* a linear relationship between dose and mutation rate has been shown for doses up to 5 R (ref. 1). Although man accumulates approximately 5 R of radiation from the environment in 30 yr of reproductive life, it is not known whether this is of any radiobiological consequence[2]. Nor is it known whether in man there is a threshold phenomenon at low doses (several hundred or thousand mr. per year), although there is greater repair of mutational or pre-mutational damage after low-dose irradiation[3]. In a coastal area of Kerala, South India, the background radiation is 1,500–3,000 mr. yr^{-1} due to the presence of thorium-containing monazite mineral in the soil[4–7] (Fig. 1). A survey of the rat population in this area with respect to several measurable and non-measurable traits and of humans with regard to dermatoglyphics and demographic data such as fertility index, sex ratio and infant mortality rate revealed no mutational effects[4,7,8]. During an epidemiological study of nodular lesions of the thyroid in this area[9], we noticed an apparently high prevalence of Down's syndrome and other forms of severe mental retardation[10]. We therefore made a house-to-house survey of developmental abnormalities in this area and in a comparable control area without high background radiation[7] (Fig. 1). We also determined the frequency of chromosome aberrations in a sample of the normal population living in the study and control areas. The observations we report here support the view that radiation-induced genetic anomalies occur with above average frequency in the population living in the area with high background radiation. The area surveyed was the southernmost one-fifth of the Chavara-Neendakara strip (Fig. 1). In the thatched huts which constitute 75% of all households, the exposure risk is 1,500–3,000 mr. yr^{-1}, and personal exposure, as measured by calcium fluoride dosimeters, closely parallels the exposure risk in the households. The control area consisted of the Purakkade–Punnapura villages, with a background radiation of approximately 100 mr. yr^{-1} (ref. 7). Households were visited repeatedly to ensure examination of all members. Only gross abnormalities evident on clinical examination were recorded. Cytogenetic abnormalities were scored blind on slides prepared from 64-h micro-blood cultures[11].

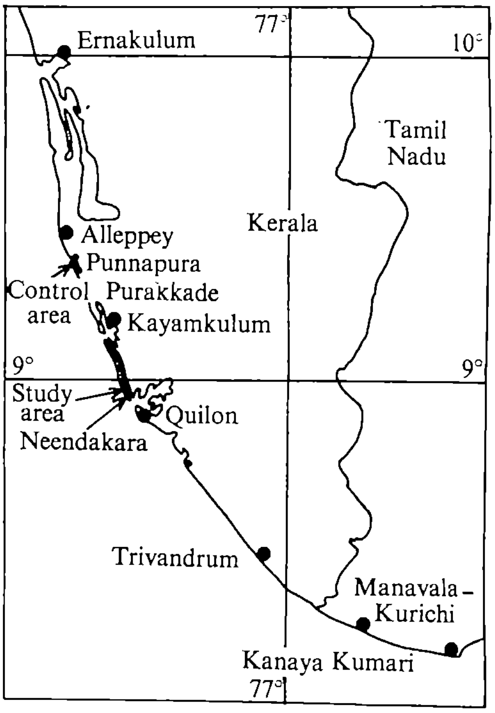

Fig. 1 Map showing the study and control areas.

Demographic and epidemiological details are reported elsewhere[9]. Briefly, the study and control populations were similar in age and sex structure, ethnic composition, living and diet habits, social customs, economic status and occupation. The mean age of all women was 30.3±7.09 yr and 30.12±7.04 yr in the study and control populations, respectively. The frequency distribution by age of women at the birth of the last child was similar in the two populations. The mean family size was 6.2 in the study and 6.4 in the control population. Rate of consanguinity was 12% in the study population and 15% in the control. Abortion rate per 1,000 pregnancies was 109 and 64.5, respectively, in study and control populations ($P > 0.05$), based on a random survey of 57 couples in the study area and 68 couples in the control area.

Table 1 Prevalence of severe mental retardation*

Type	Study population (12,918)		Control population (5,938)	
	Total	Per 1,000	Total	Per 1,000
Genetic				
Down's syndrome	12	0.93	0	0
SMR with physical abnormalities	12	0.93	1	0.17
Idiopathic	11	0.90	3	0.50
Acquired (Perinatal and postnatal)	6	0.46	3	0.50
TOTAL	41	3.1	7	1.16

The definition of severe mental retardation (SMR) is according to the WHO Classification of 1968. Figures in parentheses indicate the total number of persons surveyed.

Severe mental retardation was the commonest developmental abnormality encountered in the study area (Table 1). Clinically, 85% of the abnormalities detected in the study population were "genetic" in origin[10], compared with the 56% in the control population. The frequency of acquired retardation was comparable in the two populations. Prevalence of Down's syndrome was 0.93 per 1,000 in the study population, accounting for a third of the genetic retardations observed, whereas no cases were detected in the control population.

Chromatid and chromosome aberrations were scored in 1,705 metaphases from 46 subjects and in 1,547 metaphases from 39 individuals in the study and control areas, respectively. The mean frequency of aberrations was higher in the study area (chromatid, 3.0 ± 4.6 compared with 1.2 ± 1.9; chromosome, 1.9 ± 3.1 compared with 0.2 ± 0.6). Considering the high variance of mean aberration number, a χ^2 test was applied by grouping the data as shown in Table 2. This revealed no significant difference in chromatid aberrations between the two groups ($P > 0.05$), while the difference in the chromosome aberrations was significant ($P < 0.01$).

Table 2 Frequency of cytogenetic aberrations

% Aberrations	Chromatid		Chromosome	
	Study	Control	Study	Control
0	20	23	24	36
1–3	12	11	13	3
>3	14	5	9	0
	$P > 0.05$		$P < 0.01$	

Figures in columns 2–5 give numbers of individuals.
*These were mostly deletions (acentric fragments and minutiae), with few rings and dicentrics.

The observed frequency of Down's syndrome in the study population (1:1,076) was higher than in the control population ($P < 0.05$), and was significant for the following reasons. (1) Although no data are available on the population frequency of Down's syndrome in India, there are figures for the Eastern counties of England, 1:10,000; London, 1:3,000; Germany, 1:7,000; Denmark, 1:4,000; Australia, 1:2,083, and North-east Scotland, 1:2,000[12,13]. The frequency in Kerala is higher than in any of those (except the Shetland islands, for which the value is 1:714)[13] although infant mortality is four to five times greater than in these areas. (2) The frequency of Down's syndrome among births in India as a whole is 1:1,215 (ref. 14). In Madras, South India where the people are ethnically closer to those in Kerala, the incidence is lower (1:3,833). The frequency in the general population is expected to be lower than this because of the higher mortality among patients with Down's syndrome[15] while in Kerala the frequency is higher. (3) Most striking is the higher frequency of cases of Down's syndrome born to mothers aged 30–39 yr (Table 3). This figure of 1:81 can be compared with 1:880 and 1:290 for maternal ages of 30–34 yr and 35–39 yr, respectively, calculated by Penrose and Smith[12]. (4) The increase is also evident in a comparison of the proportion of cases of Down's syndrome born to mothers more than 30 yr old in the study area (91%) with that among 615 cases documented in India (51%)[16].

Table 3 Frequency of Down's syndrome distributed by maternal age at conception in study area

Maternal age (yr)	No. of females	% of all females	No. of cases	Frequency
20–29	862	13.6	1	1:862
30–39	729	11.5	9	1:81
40–49	532	8.4	2	1:266

Comparative figures for the distribution of females in the control population were: 20–29-yr group, 478 (16.5%); 30–39-yr group, 369 (12.7%); 40–49-yr group, 264 (9.1%). There was no case of Down's syndrome in this population.

Epidemiological and experimental evidence is accumulating which suggests an association between low dose irradiation of older mothers and non-disjunctional disorders in the offspring[17–19]. The maternal age-dependence suggests that the damaging event accelerates oocyte ageing and causes primary trisomy rather than translocation trisomy which is known to be independent of maternal age[17]. These observations agree remarkably well with our results. In 11 of 12 cases of Down's syndrome maternal age was greater than 30 yr and six of the cases who were successfully karyotyped had trisomy 21. The higher prevalence of chromosome aberrations in apparently normal subjects from the radiation area also supports the view that environmental radiation may be the cause of the genetic damage in the population. Similar cytogenetic findings have been reported from a Brazilian population living in an area of high natural radioactivity[20].

The prevalence of severe mental retardation of genetic origin was four times higher in the study than in the control population, whereas that due to acquired perinatal and postnatal causes is comparable. The nature of the genetic defect remains undetermined in most of these patients, except in the group with Down's syndrome, where trisomy 21 was demonstrated by karyotyping. Mental retardation was associated with different physical abnormalities in 12 patients in the study area. Although karyotyping was not done in these patients, chromosome imbalance is now recognised to be important in the genesis of such syndromes[21,22]. Kirman suggested that a grade of genetic defect intermediate between, on one hand, gross and visible chromosome errors, and, on the other hand, point mutations involving structural changes in the chromosomes, such as inversions and crossovers, may cause idiopathic mental retardation[23]. In view of these possibilities, radiation-induced genetic damage seems likely to be responsible for the high prevalence of mental retardation in the area we studied.

Modulation of the synthesis *in vitro* of a hormone-induced protein by transfer RNA

WE have shown that transfer RNAs (tRNAs) and the enzymes which modify their structure at the macromolecular level (tRNA methyltransferases) are under hormonal control in the target tissue[1-3]. Oestrogen-induced, cell-specific protein synthesis in immature chick oviducts has been extensively studied[4-6]. Oestrogen induces cytodifferentiation of the primitive oviduct and the consequent synthesis by the tubular gland cells of ovalbumin, conalbumin, ovomucoid and lysozyme[7]. Continuous presence of oestrogen is required for the sustained synthesis of these proteins in immature chicks; withdrawal of oestrogen is accompanied by a gradual decline in cell-specific protein synthesis[6]. The tubular gland cells in the oviduct magnum, however, continue synthesising non-secretory proteins. Readministration of oestrogen to chicks after withdrawal (secondary stimulation) results in the restoration of the synthesis of cell-specific proteins without concomitant need for DNA synthesis. We report here that in an *in vitro* tRNA-dependent protein-synthesising system from Ehrlich ascites cells, stimulation of the translation of ovalbumin mRNA was significantly enhanced by tRNA extracted from the oviduct of oestrogen-stimulated immature chicks or from the oviduct of laying hens compared with tRNA from oviducts of withdrawn chicks. Therefore, the efficiency of synthesis *in vitro* of a hormone-induced protein can be regulated by tRNA.

We had found previously that oestrogen-induced synthesis of ovalbumin can be enhanced by tRNA isolated from the oviduct of the laying hen, when it is added to oviduct explants of immature chicks[8]. To study the mechanism of enhancement of ovalbumin synthesis by tRNA we developed an *in vitro* protein-synthesising system which is completely tRNA dependent[9]. Such a system was essential for studying the contribution of tRNAs from different sources to the efficiency and fidelity of translation of a specific messenger RNA (mRNA); otherwise the residual endogenous tRNA can mask any specific effect[10].

Figure 1 shows the effect of tRNA from three different sources on amino acid incorporation. It is evident that tRNA from the oviducts of oestrogen-stimulated chicks or from oviducts of laying hens produced an enhanced stimulation of amino acid incorporation in the presence of ovalbumin mRNA (*b*, upper curve). On the other hand, the tRNAs from the three sources were equally effective in stimulating amino acid incorporation with residual endogenous mRNA.

The efficiency of translation of oviduct mRNA was also assayed by the extent of synthesis of ovalbumin and the results are presented in Fig. 2. Ovalbumin, precipitable with specific antisera, was synthesised to a 70% greater extent in the presence of tRNA from oestrogen-stimulated chicks than in the presence of tRNA from chicks that had not received secondary oestrogen stimulation.

The identity of the polypeptides precipitated by antisera was confirmed by gel coelectrophoresis with authentic markers (Fig. 3). The faster moving components are probably nascent, incomplete ovalbumin precursors. The experiments were reproducibly repeated with three different preparations of tRNA, isolated from different batches of chicks, using separate preparations of the protein-synthesising system from Ehrlich ascites cells. There were some variations in the activity of the protein-synthesising systems. In different experiments, however, ovalbumin mRNA translation was 50–75% greater by oviduct tRNA from oestrogen-stimulated chicks than from withdrawn chicks. For reproducible results it is essential to use protein-synthesising systems which depend completely on the presence of exogenous tRNA.

To rule out the possibility that the relative inefficiency of oviduct tRNA from withdrawn chicks in the synthesis of ovalbumin stems from some unknown artefact of the isolation, its effectiveness in the translation of another mRNA was tested. In the efficiency of translation of rabbit

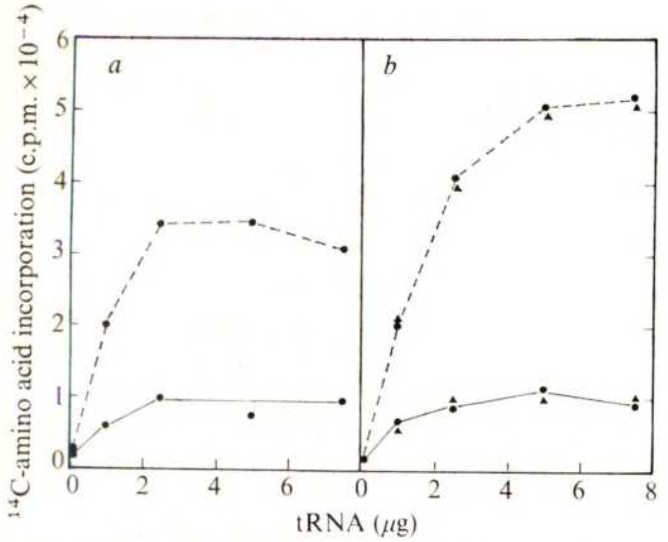

Fig. 1 Stimulation of protein synthesis by oviduct tRNA from immature chicks in a tRNA-dependent protein-synthesising system. The assay mixture contained in a volume of 100 μl: 20 mM Tris-HCl (*p*H 7.5), 1 mM ATP, 0.2 mM GTP, 6 mM creatine phosphate (all adjusted to *p*H 7.5), 20 μg creatine kinase, 0.5 μCi ^{14}C-amino acid mixture, 0.05 mM of each of the six freshly neutralised non-radioactive amino acids missing from the ^{14}C mixture, 6 mM mercaptoethanol, 50 mM KCl, 3 mM magnesium acetate, 3 μg oviduct mRNA, specified amounts of tRNA, 0.45 A_{260} units of DEAE–cellulose-passed ribosomes and 0.12 A_{280} units of ammonium sulphate fraction[9]. All incubations were carried out in duplicate at 37 °C for 90 min. The amino acid incorporation was linear up to 120 min. At the end of incubation to determine amino acid incorporation into polypeptides, 0.2 ml 0.2 N KOH was added and the tubes were further incubated for 20 min, 1 ml TCA was added and the samples were filtered through Whatman GF/C filters, washed 4–5 times with 5% TCA and once with ethanol. The filters were dried and counted in a liquid scintillation counter. *a*, Stimulation of protein synthesis with oviduct tRNA from withdrawn chicks with endogenous mRNA (●——●) and amino acid incorporation in the presence of oviduct mRNA (●- -●). *b*, Upper curve: stimulation of protein synthesis with oviduct mRNA by oviduct tRNA from oestrogen-stimulated chicks (●) or from laying hens (▲); lower curve: amino acid incorporation without oviduct mRNA. Four-day-old chicks were injected with oestradiol benzoate for 10 d followed by a withdrawal period of 3–4 weeks; the secondary oestrogen stimulation consisted of a single injection of 2 mg oestradiol[11]. Oviducts were removed aseptically, the magnum portion of the oviduct was freed of adjoining tissue and was immediately frozen in acetone-dry ice. Frozen tissue was homogenised in 5 volumes 50 mM Tris-HCl, *p*H 8.3, 5 mM EDTA, 75 mM NaCl, 0.5% SDS and an equal volume of buffer-saturated phenol in a Sorvall omnimixer at full speed for 1 min. The aqueous phase was re-extracted twice with phenol and the nucleic acids were precipitated with 0.1 volume 20% potassium acetate and 2 volumes ethanol. The tRNA was separated from the bulk nucleic acids by DEAE–cellulose chromatography and was treated with DNAse followed by Pronase[8] and extracted with phenol. The tRNA was deacylated[12] and further purified by gel filtration on Sephadex G-100 (ref. 8). Oviduct magnum tissue from 40 chicks (4–5 g) withdrawn from oestrogen for 3–4 weeks and from 5–6 chicks (5–6 g) which received secondary oestrogen stimulation, was used for the isolation of tRNA. The yield of purified tRNA from withdrawn chick oviducts was one-half (10 A_{260}) of the tRNA from secondary oestrogen-stimulated chicks. Oviduct mRNA was isolated by affinity chromatography on oligo (dT)-cellulose[13]. All glassware was dried overnight at 300 °C and the solutions were made in glass-distilled autoclaved water.

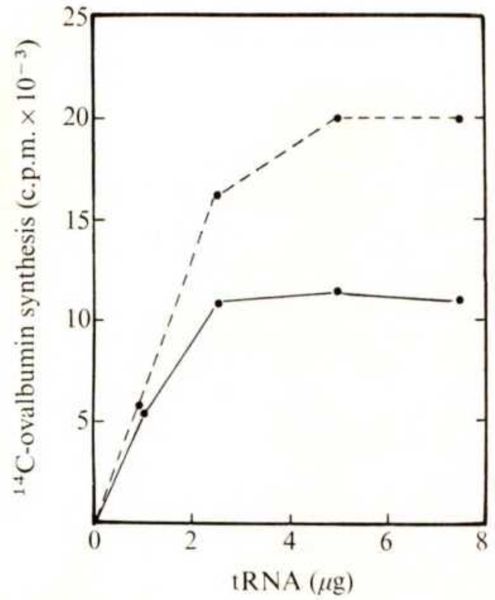

Fig. 2 Synthesis of ovalbumin in a tRNA-dependent protein-synthesising system. The details for protein synthesis were the same as described for Fig. 1. Ovalbumin synthesis was determined in aliquots of the assay mixture after incubation for 90 min at 37 °C by specific immunoprecipitation with antiserum against purified ovalbumin[14]. Aliquots (25 μl) of the reaction mixture were adjusted to 230 μl in plastic microfuge tubes (Beckman) by the addition of 15 mM NaCl in 10 mM sodium phosphate (*p*H 7.5); to this were added 10 μl ovalbumin (5 μg), 50 μl ovalbumin antiserum (antibody excess) and 20 μl 10% sodium deoxycholate. The contents of the tubes were mixed and incubated overnight at 37 °C. The precipitates were collected by centrifugation in Beckman microfuge (model 152), washed 3–4 times with 10 mM sodium phosphate (*p*H 7.5) containing 150 mM NaCl, 1% deoxycholate and 1% Triton X-100 (ref. 8). The pellet was dissolved in 0.1 ml NCS and counted[14]. Correction for nonspecific trapping of radioactivity by the immunoprecipitate was made by carrying out precipitation reactions in identical aliquots of the reaction mixture in the presence of 5 μg bovine serum albumin and 50 μl bovine albumin anti-serum. The immunoprecipitate from assay mixtures with oviduct mRNA usually contained 3,000–6,000 c.p.m. compared with 600–800 c.p.m. of nonspecific trapping. Ovalbumin synthesis was reproducibly quantified by this procedure. Ovalbumin-specific radioactivity was not precipitated from incubations in which rabbit globin mRNA or encephalomyocarditis viral RNA were translated. The specificity of the precipitation reaction was also checked by SDS–polyacrylamide gel electrophoresis of the antibody–antigen precipitate[14]. The radioactivity in the antibody–antigen precipitate from oestrogen-stimulated chick oviduct explants migrated as a single peak with the mobility of ovalbumin. Ovalbumin synthesis in the presence of oviduct tRNA from withdrawn chicks (●——●) and oestrogen-stimulated chicks (●- -●).

globin mRNA no differences were found in the tRNAs from the two sources (data not shown). The quality of the tRNAs from the two sources in the translation of mRNAs other than that of ovalbumin is also implied, albeit to a quantitatively lesser degree, by the equivalent translation of the endogenous mRNAs from the ascites cells (Fig. 1, lower curves).

Oestrogens are known to have multiple effects on target tissues. In the chick oviduct they can stimulate accumulation of specific mRNA[15–17], tRNA[18], tRNA methyltransferases[19], polysomes[11,20], endoplasmic reticulum[14,21] and factors essential for translation[22]. The findings presented here imply that the relative inefficiency of oviduct tRNA from withdrawn chicks in ovalbumin synthesis may be due to a deficiency in the population of tRNAs. The validity of such an assumption can be probed experimentally because the oviduct of the laying hen offers an abundant source of tRNAs which have a high efficiency of translation.

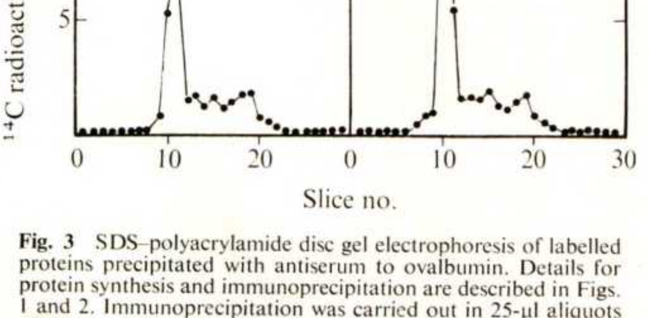

Fig. 3 SDS–polyacrylamide disc gel electrophoresis of labelled proteins precipitated with antiserum to ovalbumin. Details for protein synthesis and immunoprecipitation are described in Figs. 1 and 2. Immunoprecipitation was carried out in 25-μl aliquots of the reaction mixture of protein synthesis after 90 min incubation at 37 °C, washed antibody precipitates were mixed with ^{3}H-labelled ovalbumin and conalbumin synthesised in oestrogen-stimulated oviduct explants[14], as internal markers, and co-electrophoresed. The mobility of conalbumin (CON) and of ovalbumin (OV) is indicated. Oviduct mRNA was translated with 5 μg oviduct tRNA from withdrawn chicks (*a*) and oestrogen-stimulated chicks (*b*).

Human–mouse cell hybrid with human multiple Y chromosomes

HUMAN–mouse cell hybrids usually exhibit preferential loss of human chromosomes[1,2]. After a time interval, which depends in part on the cell types used, most or sometimes all the human chromosomes segregate out from the hybrid cells[3]. In the course of investigation of the phenomenon of preferential loss of human chromosomes from hybrids between the mouse cell line RAG and human leukocytes, we isolated and analysed sixteen human–mouse (RH) hybrids. Seven of these hybrids had retained the human Y chromosome. Five of these had only one copy per cell of Y, one had two copies per cell and one, RH-28, had four copies of the Y in many cells. We decided to study more extensively this hybrid which seemed to have lost all the human chromosomes except number 17 and the Y.

Figure 1 shows a cell of RH-28 stained by the Q-banding technique which has four human Ys and a human chromosome 17. We determined the distribution of Y chromosomes in 95 cells of RH-28. The results presented in Fig. 2 show that the majority of the cells screened had three or four Y chromosomes. In a few cells the number of Y chromosomes was even higher. In one cell which had a much larger number of mouse chromosomes there were ten human Y chromosomes. The only other human chromosomes present in these hybrid cells was a single copy per cell of chromosome 17.

The presence of multiple copies of a specific human chromosome in human–mouse cell hybrids has been reported by Green *et al.*[4]. In their hybrids, the mouse parent was a thymidine kinase deficient (TK^-) mutant and Green *et al.* could, therefore, select for retention of human chromosome 17, which contains the *TK* gene. They tried to select lines with a high number of human chromosomes 17 by selecting subclones which grew in HAT medium containing low concentrations of thymidine. Three of ten subclones had higher mean numbers of chromosome 17.

We subcloned hybrid RH-28 to see whether we could select subclones in which all or most of the cells had the same number of Y chromosomes. The results (Fig. 3) indicate that in some of the subclones there was a stable number of Y chromosomes. Thus in subclone 8 all 25 cells scored had four Y chromosomes. In another subclone, 2, 30 of 34 cells scored had four Y chromosomes. In several other subclones the Y chromosomes seemed to have stabilised at a lower number per cell. In subclones 1, 3, 5

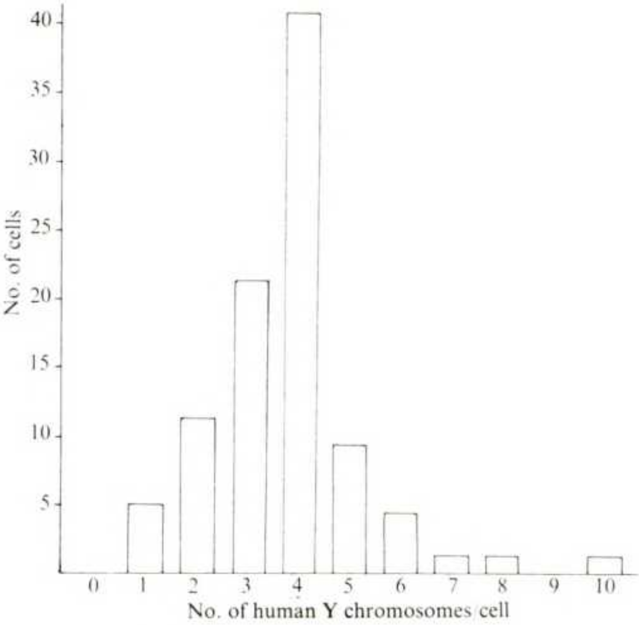

Fig. 2 Distribution of human Y chromosomes in cells of human–mouse hybrid RH-28.

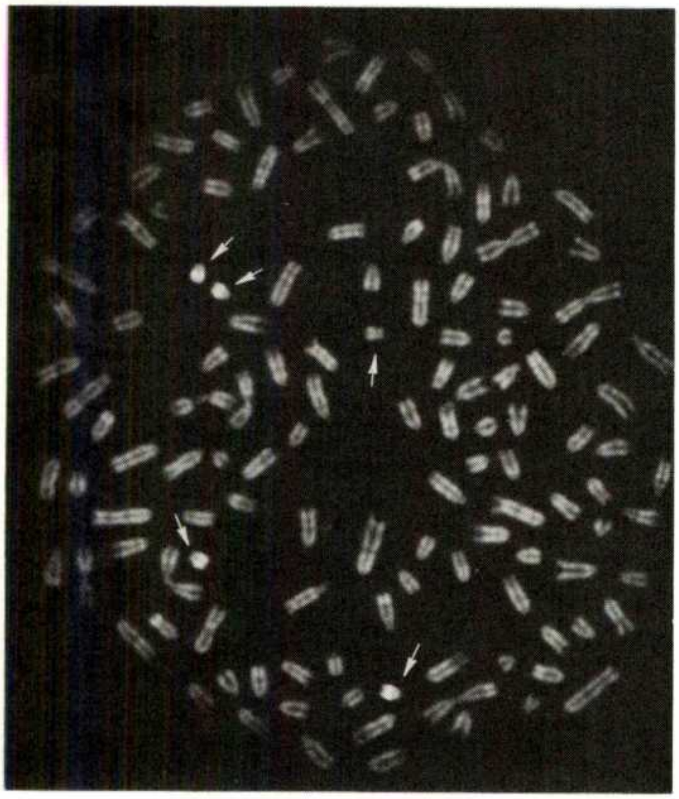

Fig. 1 A metaphase cell from RH-28 in which the human number 17 and four human Y chromosomes are indicated by arrows. The mouse parental line used in the hybridisation experiment was the hypoxanthine-guanine-phosphoribosyltransferase deficient (HPRT⁻) RAG cell line[8]. The other parental cells were unstimulated leukocytes from a human male. The cells were induced to fuse by β-propio-lactone inactivated Sendai virus[9,10]. Hybrids were selected in HAT medium[11]. The isolated hybrids were maintained in MEM medium. Four–six weeks after fusion, cells from 16 hybrids were collected, chromosome preparations made and the chromosomes identified by quinacrine banding patterns[12].

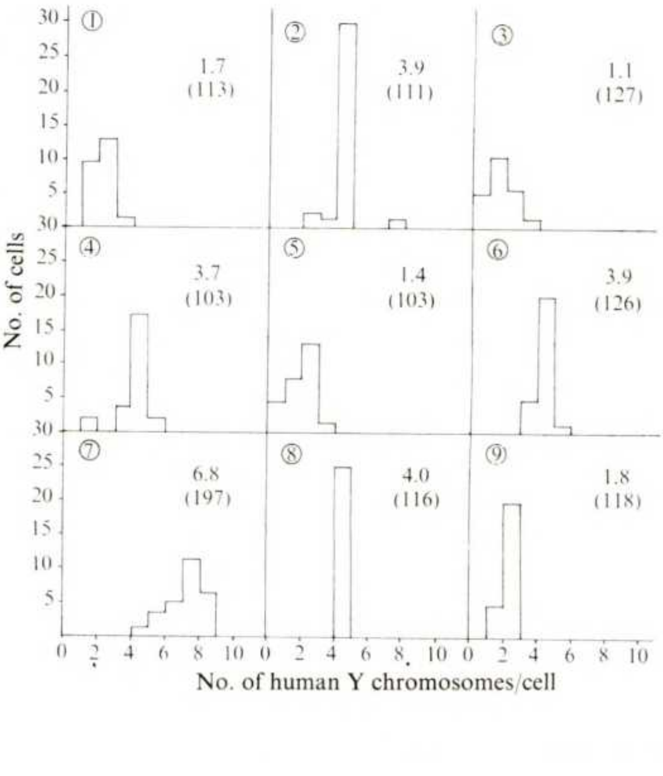
Fig. 3 Distribution of human Y chromosomes in cells from nine subclones of hybrid RH-28. The mean number per cell of human Y chromosomes and the mean number per cell of mouse chromosomes ( ) is included for each subclone.



and 9, 85 of 97 cells scored had only one or two Y chromosomes. A different situation was found in subclone 7 in which the number of mouse chromosomes doubled and the number of Y chromosomes in the majority of cells scored was between six and eight per cell. This subclone was stable over a period of at least 100 generations with respect to the doubled number of mouse chromosomes and the number of human Ys. In most of the cells of the nine subclones one copy of human chromosome 17 was still present.

If the accumulation of the Y chromosomes in hybrid RH-28 resulted from non-disjunction and selection for multiple Y chromosomes per cell, then the stability of some subclones with four and others with only one or two Y chromosomes indicates that the frequency of non-disjunction and selection has decreased. This phenomenon of accumulation of the Y chromosome may be analogous to the accumulation of B chromosomes in a variety of species[5].

Mittwoch and Kirk[6] showed that in mammals, gonadal cells which contain a Y chromosome grow faster than cells which do not contain a Y. It is tempting to speculate that the selection for cell hybrids with multiple Y chromosomes is due to a faster rate of growth.

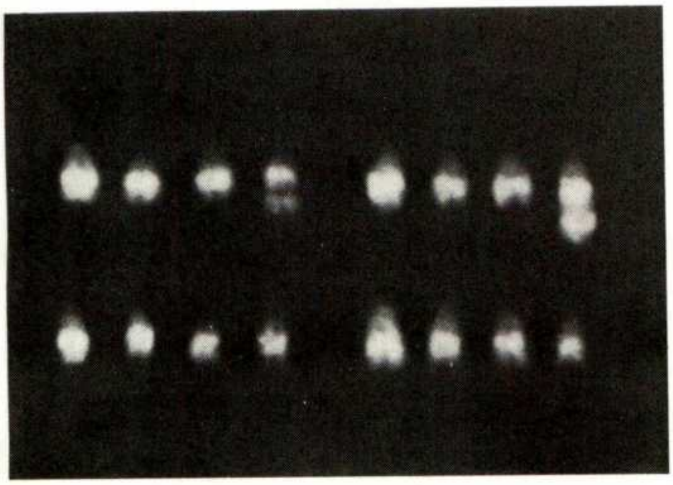


Fig. 4 Upper, human Y chromosomes from two cells of subclone 2. The Y chromosome on the right of each group is longer and has two quinacrine bright bands. Lower, human Y chromosomes from an RH-28 cell and a cell from subclone 6. Several of these Ys have a dull distal region.

In several subclones of the RH-28 hybrid the Y chromosome seemed to have undergone rearrangements which we are now investigating. Thus, in subclone 2 there were usually four Y chromosomes per cell. Three of these seemed to be normal whereas the fourth was almost twice as long and possessed two wide quinacrine bright bands instead of one (Fig. 4). In other cells, some of the Y chromosomes were altered in a different way, having a dull area distal to the bright band (Fig. 4).

The availability of human–mouse hybrid cell lines containing the human Y may enable us to isolate and characterise proteins which are produced by Y linked genes, for example the H–Y antigen[7]. To facilitate this we have already obtained subclones that have lost the only other human chromosome present, number 17, but have retained multiple copies of the Y chromosome.

Chromosomal proteins regulate steroid binding to chromatin

STEROID hormones accumulate in their respective target cells due to the presence of "receptor" proteins which bind the steroid with high affinity and specificity[1–4]. It seems that the steroid–receptor complexes then migrate and bind to nuclear chromatin[2–5]. Within about 15 min there is an alteration in transcription which is followed after 2 h by the appearance of specific messenger RNAs[6–9]. At present, the mechanism by which steroids alter gene expression is obscure. The group in our laboratory is attempting to identify the nuclear (or chromatin) component which binds the progesterone–receptor (P–R) complex because it is possible that the macromolecules involved are also involved in the steroid-induced modifications of gene expression. We have demonstrated recently more than one class of binding sites in chick oviduct nuclei *in vivo* and in hen oviduct nuclei and chromatin *in vitro*[10–12,13]. The highest affinity class of sites, representing 5,000–10,000 sites per cell nucleus, is suspected to be the biologically important class, because: (1) it is the only class which binds P–R *in vitro* in physiological ionic conditions (0.15–0.20 M KCl); (2) it is the only class bound *in vivo* when the steroid is at physiological levels in the serum; (3) binding to whole chromatin is tissue-specific, found only in oviduct chromatin, and (4) when these sites are saturated *in vivo* with the P–R, maximal responses of the RNA polymerase I and II activities are observed *in vitro*. Although additional nuclear binding to the sites of weaker affinity can be achieved *in vivo*, this causes no further alteration of polymerase activities[13]. We have also found that the low ionic conditions (0.01–0.05 M KCl), often used in binding assays, result in a pattern of nuclear binding which is non-saturable and shows no tissue specificity. When the ionic strength of the binding assays is increased to 0.15 M or 0.2 M KCl, there is a saturable, tissue-specific binding which measures selectively only the highest affinity class of binding sites[10–12]. We now present evidence which suggests that one fraction of the non-histone protein (NHP) (called AP_3) is involved in the high affinity binding of P–R to the chromatin of the progesterone target tissue—oviduct—while other fractions (AP_1 or AP_2) are involved in masking these binding sites. We also present data which indicate that the high affinity binding sites are present but completely masked in non-target tissues.

Figure 1 shows high affinity binding (that is, binding assayed in 0.15–0.2 M KCl) of P–R to hen oviduct nuclei and chromatin *in vitro*. The same high affinity binding to chick oviduct nuclei *in vivo* is shown for comparison. When the histones were removed, the *in vitro* binding was only slightly greater than that of whole chromatin. But when the acidic protein fractions AP_1 and AP_2 were also removed, the level of the high affinity binding to the oviduct material was enhanced four to fivefold. Finally, the removal of the remaining NHP (representing the AP_3 fraction) resulted in a loss of practically all high affinity binding. These results strongly support a role of NHP both in constituting part of the high affinity sites and in the masking of these sites in the oviduct (target tissue) nucleus. If the dissociated proteins were reconstituted back to the DNA, the high affinity sites were not only reinstated in the reconstituted hen oviduct chromatin but also at the same relative levels as the untreated hen oviduct chromatin, that is, the high affinity sites as well as the masking were restored. This ability to restore the native levels of binding to reconstituted chromatins was demonstrated previously with chick oviduct[14,15].

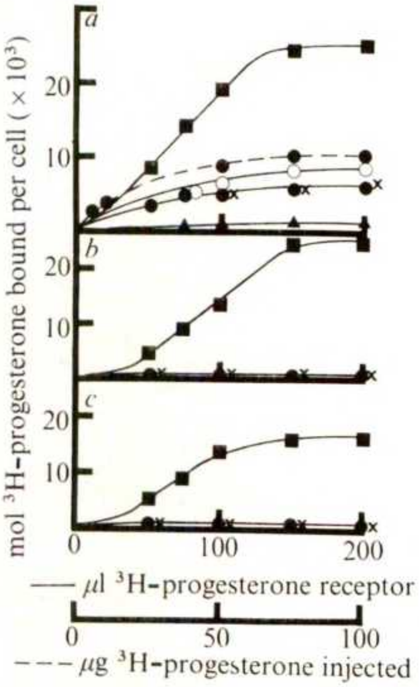

Fig. 1 Binding of ^{3}H-progesterone to high affinity sites in the nuclear material of oviduct (*a*), spleen (*b*) and erythrocytes (*c*) of the chicken. – – –, Binding to nuclei of the chick oviduct *in vivo* as described elsewhere[13]; ——, binding *in vitro* using isolated nuclear components and ^{3}H-progesterone–receptor complex as described elsewhere[11,12]. The *in vitro* binding to the soluble DNA–protein complexes was performed using streptomycin to precipitate the protein–DNA complexes, bound with the ^{3}H-progesterone–receptor complex, or using protein–DNA complexes attached to cellulose as described elsewhere[10]. High affinity binding *in vitro* was assayed under 0.15 M KCl using 0–200 μl of labelled receptor and 50 μg of DNA (as chromatin or protein–DNA complex). The removal of total histones as well as AP_1, AP_2 or total protein has been described elsewhere[2,12,14,15]. The efficiency of removing these fractions from chromatin DNA and the integrity of the nuclear components were assayed by polyacrylamide gel electrophoresis and quantitation of the protein: DNA using the Lowry[18] and diphenylamine[19] methods. The ^{3}H-progesterone–receptor complex was isolated, partially purified and assayed for its integrity as described elsewhere[11]. The symbols represent binding to: ●, isolated nuclei; ×, whole chromatin; ○, chromatin deficient in histone; ■, chromatin deficient in histone, AP_1, AP_2, and ▲, chromatin deficient in total protein (pure DNA). The number of molecules of ^{3}H-progesterone bound per cell was calculated using the specific activity of the steroid (47 Ci mmol^{-1} for the stock solution), 2.5×10^{-12} g DNA per diploid cell of the hen organs[20], and 26% counting efficiency. The 10,000 molecules bound per cell represents 180,000 c.p.m. per mg of DNA or 9,000 c.p.m. per assay (50 μg DNA).

Table 1 Extent of masking of high affinity sites

Source	Level of binding at saturation (molecules per cell)	% Total sites masked
Oviduct nuclei *in vivo*	10,600	58
Oviduct nuclei *in vitro*	5,951	76
Oviduct chromatin	7,441	71
Oviduct chromatin –histone	9,278	53
Oviduct chromatin –histone –AP_1, AP_2	25,290	0
DNA	2,055	—
Spleen nuclei	60	100
Spleen chromatin	48	100
Spleen chromatin –histone –AP_1, AP_2	24,106	0
Erythrocyte nuclei	357	98
Erythrocyte chromatin	416	97
Erythrocyte chromatin –histone –AP_1, AP_2	15,018	0

These data were taken from values in Fig. 1. The number of binding sites measured in each of the chromatin–histone AP_1, AP_2 preparations was assumed to represent the total sites in the respective chromatin and thus each of these preparations was assigned a 0% masking. The values at saturation for each preparation were taken at 100 μg of injected hormone for the *in vivo* binding and at 200 μl of labelled receptor preparation for the *in vitro* binding. The preparations of the nuclear components as well as the hormone binding assays were performed as described in the legend of Fig. 1.

It is interesting that the nuclei and chromatin of non-target tissues (hen spleen and erythrocyte) showed little high affinity binding (Fig. 1). The removal of histones and NHP fractions AP_1 and AP_2, however, resulted in a level of binding approximating that of the target tissue (hen oviduct). Thus, although the non-target tissues showed none or a few nuclear high affinity sites, these sites were present but completely masked by protein (Table 1). Assuming that all acceptor sites were unmasked in the chromatins devoid of histones, AP_1 and AP_2, the *in vivo* binding to chick oviduct nuclei showed 58% masking. The *in vitro* binding to hen oviduct nuclei/chromatin exhibited about a 60 to 80% masking while that to hen spleen or erythrocyte nuclei/chromatin showed essentially 100% masking.

The biological need for an apparent distribution of high affinity binding sites throughout the animal and the masking of them remains obscure. It would be interesting to assess whether or not the extent of masking varies under normal biological influences. Along these lines, Chatkoff and Julian[16] reported that progesterone treatment of ovariectomised rabbits caused an increase in the binding of oestrogen–receptor complex *in vitro* to uterine nuclei. Similarly, Spelsberg *et al.*[17] found that the levels of binding of the progesterone–receptor complex to oviduct nuclei *in vitro* varied during the oestrogen-induced development of the chick oviduct. Both these studies involved the high affinity sites described here because physiological ionic conditions were used in binding assays. The question arises whether or not transformed cells in culture or in mammary tumours which contain steroid receptors but which do not respond to the steroids, have masked nuclear "acceptor" sites. Thus, these cells may be unresponsive since the genome cannot bind the steroid–receptor complexes.

Effect of maternal age on intercellular adhesion of embryonic chick liver cells

In appropriate conditions single cells obtained by dissociation of embryonic tissues form organised cell masses resembling tissues. We wish to present results indicating that the adhesive properties of chick embryonic cells depend on maternal age. These unexpected observations were made in studies on the mechanism of intercellular adhesion. The formation of initial aggregates between chick embryonic liver cells is a two-step process[1]; cells rapidly and reversibly bind to each other to form aggregates in a step that is not inhibited by metabolic poisons. The reversibly bound cells are then converted into stably bound cells in a process requiring metabolic energy.

Current studies are concerned with the formation of stable bonds between chick embryonic liver cells. The formation of such bonds was stimulated by the addition of L-ascorbic acid and L-glutamine (or D-glucosamine); these compounds promoted the adhesion of more single cells, and the resulting aggregates were larger and appeared more compact. As shown here, however, this stimulation depended on the age of the hen from which the embryo was derived.

The addition of ascorbate and glutamine to single cells derived from the embryos of younger hens (about 20 weeks old) increased the number of cells in aggregates after 40 min by 30–50% (Fig. 1). In contrast, the aggregation of cells derived from older hens (about 40 weeks) was not altered significantly by ascorbate and glutamine. The mechanism of action of ascorbate and glutamine is being studied and the results will be presented elsewhere.

Eggs from White Leghorn chickens (Truslow Farms, Maryland) and suspensions of liver cells from 12-d-old embryos were prepared by a modified method of Howard *et al.*[2]. The cells, suspended in Earle's salt medium, were incubated on a rotary shaker (about 3×10^5 cells in 0.3 ml) and allowed to aggregate as described before[1]. The rate at which single cells formed aggregates was determined with a Coulter electronic particle counter[3]. Only single cells were counted, so that the number of single cells remaining in suspension decreased as aggregation proceeded. The decrease in single cells was an accurate measure of cell aggregation.

In a typical experiment with embryos from younger hens (27 weeks) 50% of the cells aggregated in 40 min. The addition of ascorbate and glutamine increased the extent of aggregation to about 75% (Fig. 1). When embryos from older hens (35 weeks) were used as a source of cells, however, no stimulation was obtained after addition of ascorbate and glutamine (Fig. 1).

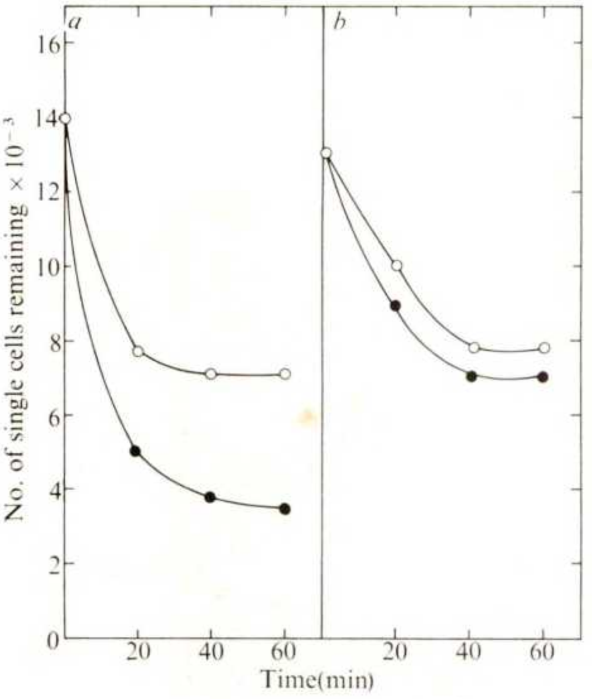

Fig. 1 Stimulation of liver cell aggregation by ascorbate and glutamine. Liver cells (2.9×10^5 cells, 0.3 ml) were allowed to aggregate at 37 °C in a rotary shaker in standard conditions[1] in the presence or absence of ascorbate (0.6 mg ml^{-1}) and glutamine (2.7 mM). After incubation, cells were diluted with 10 ml of cold balanced salts solution and the single cells remaining (after dissociation of the reversibly bound cells) were counted. The data presented are not multiplied by the constant dilution factor. *a*, Liver cells of embryos derived from younger hens (27 weeks) were incubated without additions (○) or with ascorbate and glutamine (●). *b*, Liver cells of embryos derived from older hens (35 weeks) were incubated without additions (○) or with ascorbate and glutamine (●).

The stimulation obtained by adding ascorbate and glutamine varied with the age of the laying hens (Fig. 2). This dependence on maternal age was observed with five different flocks of hens, and when 9- or 10-d-old embryos were used instead of 12-d-old hens. It was not influenced by the season of the year, indicating that the phenomenon was not affected by light–dark cycles nor moderate changes in temperature. The chickens were fed on an 18% protein breeder's mash without antibiotics, but with adequate vitamin C.

The livers of embryos from younger hens were also more readily dissociated into single cells than the livers of embryos from older hens. Not only was a higher yield of cells obtained after collagenase–hyaluronidase treatment of younger hens, but the preparations typically contained 50–80% single cells (the remaining cells were in aggregates of 2–20 cells) whereas livers from the embryos of older hens gave only 10–20% single cells.

Since the single cells were prepared with collagenase and it is well known that ascorbate is involved in the biosynthesis of collagen[4], it seemed possible that both cell yield and response to ascorbate might be related to collagen structure. One aspect of the structure that is important for mechanical stability of collagen fibres is the amount of covalent intermolecular cross linking. Furthermore, the amount of collagen cross linkage is increased with age in many animals[5]. But treatment *in vivo* with β-aminopropionitrile

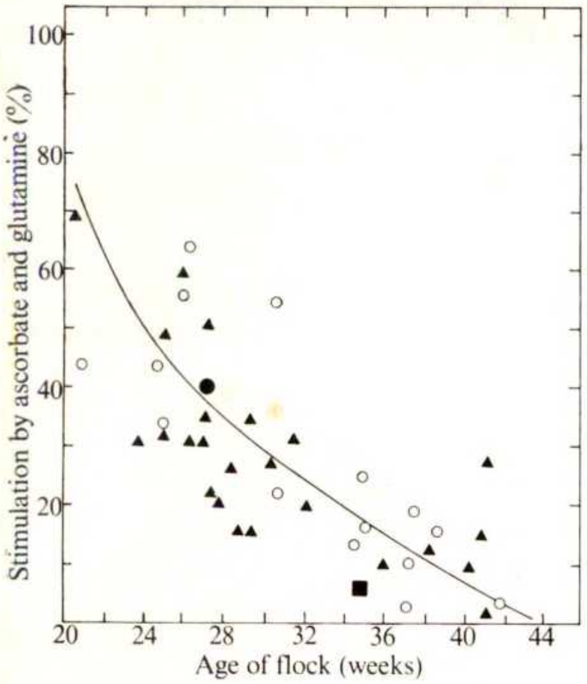

Fig. 2 Effect of maternal age on the stimulation of cell aggregation by ascorbate and glutamine. In each experiment about 3 × 10^6 liver cells were incubated in 0.3 ml of balanced salts solution on a rotary shaker at 37 °C. After 40 min, the samples were diluted with 10 ml of cold balanced salts solution and the number of single cells remaining was determined. To some of the vials L-ascorbate (0.7 mg ml^{-1}) and L-glutamine (27 mM) were added. The data presented here were obtained from two different flocks of chickens, one started in March (○) and one in August (▲). The abscissa indicated the age of the hens (note that efficient egg production began at 20 weeks), and the ordinate the percentage increase in the number of cells stably bound in aggregates caused by the addition of ascorbate and glutamine. The data in Fig. 1*a* were obtained in March and are indicated by ●; the data in Fig. 1*b* were obtained in May and are indicated by ■ in this figure.

(which inhibits cross linking[6,7]) had no effect on the response to ascorbate *in vitro*, suggesting that collagen cross linking was not involved in the age-dependent stimulation of aggregation by ascorbate.

Although the mechanism underlying the observations reported here is unknown, maternal age seems significantly to affect the adhesive properties of embryonic cells *in vitro*. If *in vitro* adhesiveness as measured in these studies reflects *in vivo* histogenesis, the elucidation of the mechanism by which maternal age affects cell adhesion may ultimately shed light on the relationship between birth defects and maternal age.

We thank Dr Björn Öbrink for helpful discussion. These studies were supported by grants and a contract from the NIH and a grant from the American Cancer Society. J. Umbreit was a postdoctoral fellow of the Jane Coffin Childs Memorial Fund for Medical Research and NICHHD.

Limited proliferation of stem cells surviving alkylating agents

HAYFLICK observed that when human foetal tissue was cultivated *in vitro* the cells underwent 50±10 population doublings before death[1]. Whether this phenomenon is a property of all diploid cells in culture and is pertinent to cell renewal systems *in vivo* has been the subject of much discussion. Haematopoietic failure is rarely the cause of death in animal or man, presumably because this cell renewal system has a proliferative capacity which is either unlimited or, if limited, exceeds the life span of a normal animal. The proliferative capacity of the haematopoietic system, if restricted, might become exhausted when stressed by the prolonged use of cytotoxic agents. In these circumstances, significant stem cell division would be necessary to return to the steady state, thereby using much of the stem cell proliferative capacity. We have carried out experiments in mice attempting to simulate the clinical use of chemotherapeutic agents that might result in exhausting the proliferative capacity of haematopoietic stem cells. Two alkylating agents, Busulfan and L-phenylalanine (L-Pam) were investigated. Mice treated with Busulfan and to a lesser extent L-Pam demonstrate permanent damage to the proliferative capacity of surviving stem cells as measured by serial transplantation. Such data may have relevance to the use of these agents in the clinic where there is great interest in such agents to destroy presumed subclinical micrometastases in patients expected to have extended survival.

Using the haematopoietic system of mice, many investigators have attempted to demonstrate premature senescence *in vivo*. This system is useful because serial transplantation of bone marrow can be used as a measure of the proliferative capacity of haematopoietic cells. Further, the spleen colony-forming unit (CFU)[2] facilitates direct measurement of a stem cell population. Siminovitch *et al.*[3] demonstrated a decline in colony-forming ability of haematopoietic cells subjected to serial transplantation into lethally irradiated recipient mice. Metcalf and Moore[4] varied the interval between passages from 14 d to 187 d, and in spite of this increased interval observed progressive decline in CFUs per spleen. In a subsequent experiment, they used 10-d foetal liver and compared its transferability with that of marrow from both young and old mice. Foetal haematopoietic tissue sustained six passage generations, whereas young and old marrow cells survived only three such passages, suggesting that haematopoietic stem cells may have limited divisional capacity with most divisions taking place in the foetal period.

Others[5,6] feel that limited proliferative capacity is not a characteristic of stem cells. With prolonged intervals between passage, the transplanted marrow tends to regain normal CFU levels. No method has been used, however, to distinguish host from donor CFU. When such determinations were made, it was found that with increased number of passages and long intertransplant time, donor cells disappeared and host cells predominated[7].

We used C3H/HeJ male mice treated with Busulfan or L-Pam. The choice of Busulfan was based on the report by Morley and Blake[8] showing that high doses of Busulfan can cause aplastic anaemia in surviving mice. The choice of L-Pam was based on the current clinical use of this drug for two years to treat presumed subclinical micrometastases in patients with seemingly localised breast cancer[9]. We suggest that certain drugs given in low doses might cause enough stem cell depletion and subsequent division to limit the proliferative potential of the haematopoietic stem cell. We used serial transfers as a method of increasing the number of stem cell divisions and thus elicit defects in the

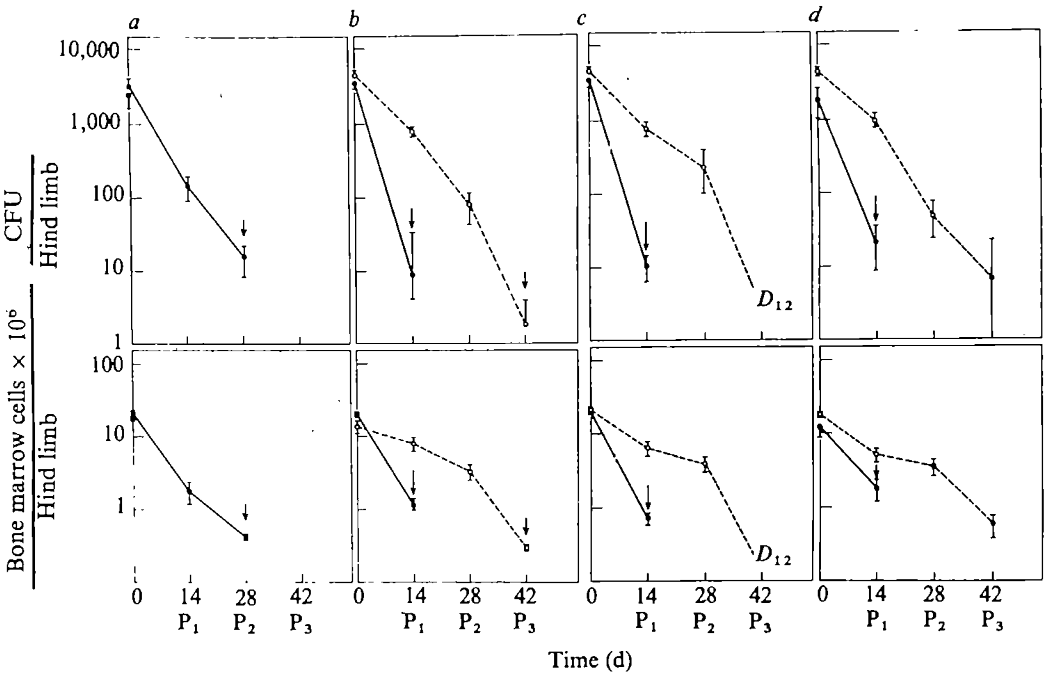

Fig. 1 Comparison of transferability of normal (○)compared with Busulfan-treated marrow (●). Arrow denotes inability to passage further due to insufficient cells. D_{time} denotes date of death of last passaged mouse. *a*, 5; *b*, 10; *c*, 15; *d*, 20 weeks post-drug.

proliferative capacity of the stem cell population that might not otherwise become apparent.

To avoid drug-induced death, drug doses were chosen to correspond to half the LD_{10} (ref. 10) (0.18 mg Busulfan and 0.068 mg L-Pam). These agents were given intraperitonally six times at weekly intervals. A control group was maintained in the same conditions as the experimental group and received weekly injections of the diluent. Peripheral blood counts were carried out weekly on tail vein blood samples of the experimental group during the period of drug administration and once every 2 weeks thereafter. No mouse was bled more than once every 16 weeks. Control mice were bled once every 4 weeks. Five weeks after drug completion, three mice from the control and experimental groups were killed for serial marrow passages into lethally irradiated recipients that received a whole body dose of 1,200 rad in divided doses of 700 and 500 rad separated by 3 h. The transfers were carried out every 5 weeks. One million cells were injected into ten lethally irradiated mice at each passage interval, and 14 d separated each passage. At the time of each passage, marrow cellularity was determined, and ten lethally irradiated mice were injected for spleen colony determinations as described previously[11].

The effect of Busulfan on the ability to passage marrow cells is illustrated in Fig. 1. At 5 weeks after drug administration, the Busulfan marrow could be passaged for 28 d. At 10 weeks, passage was only possible for 14 d, as compared with 42 d for controls. These same patterns continue at 15 and 20 weeks post-drug. Marrow CFU per hindlimb before transfer was normal at 10 weeks, whereas at 15 and 20 weeks it had dropped to less than normal levels. On the other hand, marrow cellularity in the non-passaged state does not fall below normal until 20 weeks post-drug. Peripheral blood counts at all these transfer times (5–20 weeks post-drug) were normal.

The effect of L-Pam on the CFU is not as marked (Fig.

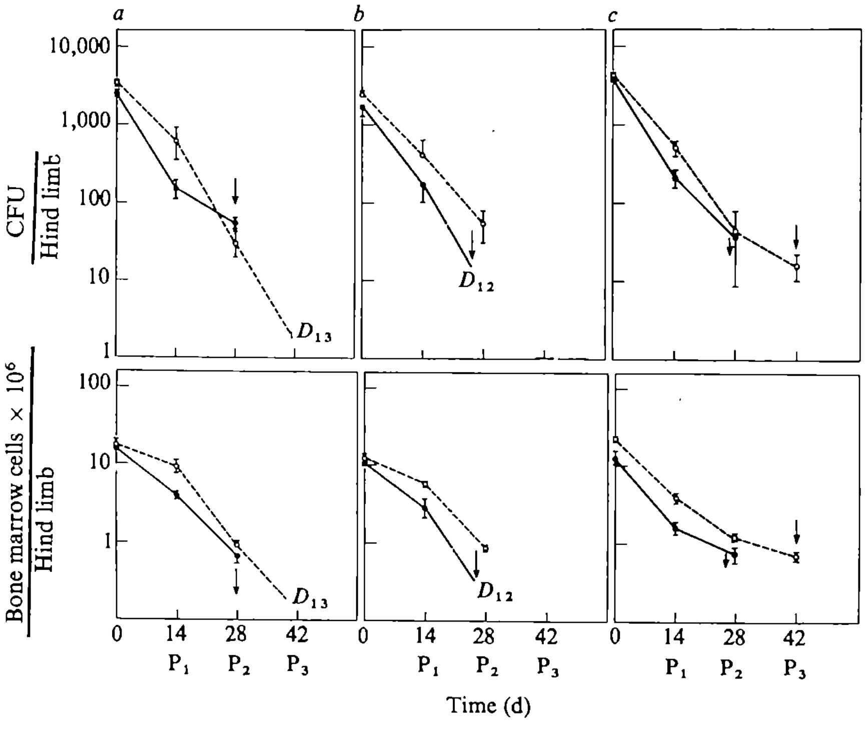

Fig. 2 Comparison of transferability of normal (○) compared with L-Pam-treated marrow (●). Arrow denotes inability to passage further due to insufficient cells. D_{time} denotes date of death of last passaged mouse. *a*, 5; *b*, 10; *c*, 15 weeks post-drug.

2). At all transfer times (5–15 weeks) L-Pam could not be passaged longer than 28 d, whereas control groups were kept in passage for 41 or 42 d. Marrow CFU and cellularity before transfer showed no difference compared with normal controls. The results are not as dramatic as those for Busulfan but are qualitatively similar as regards serial transplantation.

Considerations of seeding efficiency are complex and cannot easily explain the findings since with Busulfan the number of CFUs markedly decreased with each passage compared with control: whereas with L-Pam at 5 and 15 weeks the number of CFUs is similar to the control, but with both drugs there is a difference in serial transfer. There was no difference in spleen colony size between control and experimental groups at any stage of transfer. Detailed microscopic evaluation of the colonies, however, was not carried out.

Our results support the concept of there being limitations on the proliferative capacity of normal cells. Although limitation of proliferative capacity of the haematopoietic stem cell compartment is usually not an important constraint on life span, it may become critical when stressed by a prolonged application of, for example, Busulfan. An alternative but less likely explanation of these data is that the drugs cause the surviving cells to have a longer generation time and thus undergo less proliferation during each passage. This seems unlikely since the CFU number in the L-Pam groups after transfer was not decreased compared with control, although their ability to passage was decreased (28 compared with 42 d). Furthermore, Busulfan-treated mice showed a progressive decrease in passage ability (28 d at 5 weeks and 14 d thereafter), CFUs per hindlimb, and bone marrow cellularity per hindlimb.

Further work is necessary to determine whether marrow failure occurs as a result of these demonstrated defects in proliferative capacity. Although marrow failure may take many months to develop, its occurrence can be expected based on the results of Morley[12]. Experiments using other classes of cytotoxic agents[13] will be carried out to determine whether the stem cell can be spared by the use of such drugs. In the adult mouse and perhaps in man, the stem cells are proliferatively inactive; thus agents affecting only cells in cycle may be useful for destruction of micrometastases without causing significant stem-cell depletion.

We thank M. Ott and H. Grate for assistance. This work was supported by grants from the USPHS.

Transformation of the β_2 adrenoceptor in normal rat liver into a β_1 type in Zajdela hepatoma

IN a large variety of tissues, malignant transformation is accompanied by changes in the cyclic AMP system[1]: adenylate cyclase may be functionally absent or modified, while various quantitative alterations of hormonal membrane receptors may also occur[2]. In liver, although the cyclase response to various activators may differ from one type of tumour to another[3] as well as during the process of carcinogenesis itself[4,5], an enhanced response to catecholamines is generally observed[4,6]. Here we describe gross modifications of the adenylate cyclase system in Zajdela ascites hepatoma cell line. Among these modifications is a hitherto undescribed qualitative alteration of the adrenoceptor.

Zajdela hepatoma, which was studied in the present work together with normal liver, was originally derived from parenchymal liver cells after chronic administration of dimethylaminoazobenzene[7]. It retains certain characteristics of the original cell[7] and, for example, it can resynthesise glycogen in certain culture conditions[8]; thus it can be justifiably compared with normal liver[9,10,11]. The animals used in this study were female, albino Wistar rats (~200 g body weight). A particulate fraction was prepared from normal liver by disruption with a Dounce homogeniser in 5 volumes (v/w) of 1 mM $NaHCO_3$. After two washing steps, which were performed by centrifugation at 2,000*g* for 10 min at 4 °C, the plasma membrane-enriched pellets were resuspended in the same $NaHCO_3$ solution (2 ml per g of liver). The corresponding fraction from Zajdela hepatoma was prepared from 20–50 ml of ascites fluid. Tumour cells were freed from contaminating erythrocytes by several washes in 0.2% NaCl. They were subsequently lysed in 1 mM $NaHCO_3$ for 10 min at 4 °C and the particulate fraction prepared as described for normal liver. As shown in Table 1, the cyclases from these two preparations had quite different activities in the absence as well as in the presence of stimulating agents. In the hepatoma, basal activity was ten times lower than in normal liver and hormonal responsiveness was altered in many ways. The effect of glucagon was detected only when its concentration was higher than 1 μM, which corresponded to a supramaximal concentration in

Table 1 Adenylate cyclase activity of Zajdela hepatoma and normal liver

		Adenylate cyclase activity (pmol per mg protein per 10 min) Normal liver	Zajdela hepatoma
Basal		95 ± 4	9.8 ± 0.5
+ adrenaline	(50 μM)	139 ± 6	170 ± 6
+ Glucagon	(1 μM)	1,300 ± 30	17.1 ± 0.6
+ NaF	(10 mM)	1,010 ± 16	196.4 ± 4.5
+ GTP	(0,1 mM)	198 ± 25	9.2 ± 0.4
+ GTP + Adrenaline		340 ± 30	162 ± 5

Adenylate cyclase activity was measured as described previously[12]. The assay medium contained 0.5 mM α-^{32}P-ATP (10^6 c.p.m.), 3 mM $MgCl_2$, 1 mM EDTA, 1 mM cyclic AMP, 50 mM Tris-HCl, *p*H 7.6, an ATP-regenerating system (consisting of 25 mM phosphocreatine and creatine phosphokinase (1 mg ml^{-1}) and the enzyme fraction (100–200 μg protein per assay) in a final volume of 60 μl. Incubation was initiated by the addition of the enzyme preparation and was performed for 10 min at 30 °C. Reactions were terminated according to White[13]. Protein was estimated by Lowry's procedure using bovine serum albumin as standard. Results are expressed in nmol of cyclic AMP formed in 10 min per mg of protein at 30 °C. Data represent the means ± s.e. of 3 experiments in which each point was assayed in triplicate. The mean responses differ from the basal activity with $P < 0.01$. It should be noted that the liver cyclase activated by catecholamines was completely inhibited by propranolol, a specific β antagonist. Addition of α-adrenergic blockers such as phentolamine or phenoxybenzamine did not alter the cyclase activity. α agonists such as oxymethazoline were completely ineffective (data not shown).

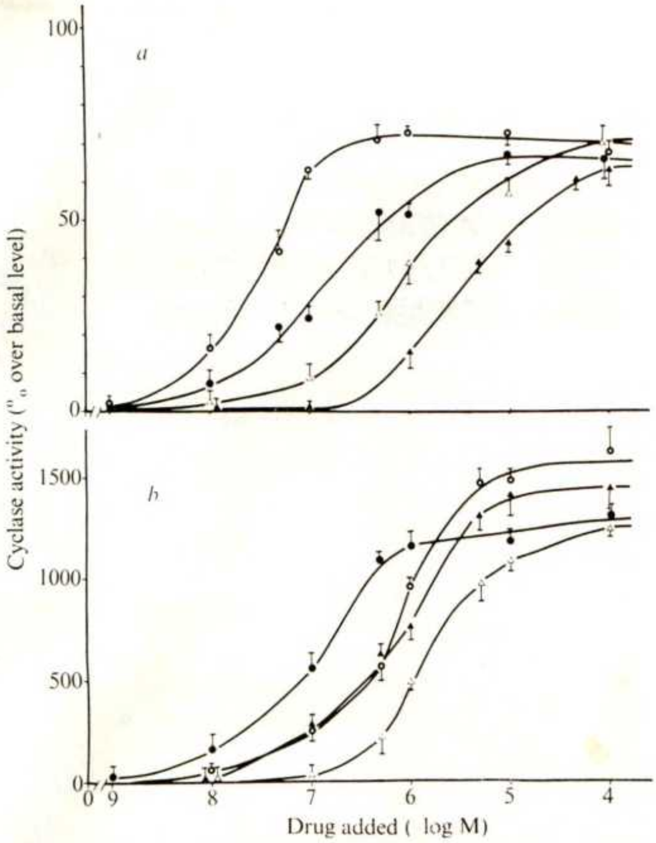

Fig. 1 Effect of various catecholamine agonists on cyclase activity. The enzyme preparations from normal liver (*a*) and from Zajdela hepatoma (*b*) were incubated as described in the legend to Table 1 and in the presence of varying concentrations of protokylol (○), isoproterenol (●), adrenaline (△) or noradrenaline (▲). The cyclase activity is expressed as percentage increase over the basal level (basal values are respectively 95 ± 4 and 9.8 ± 0.5 pmol cyclic AMP formed in 10 min per mg of protein in normal liver and in Zajdela hepatoma). Values represent the mean of three determinations; the standard errors are indicated by the bars. The apparent K_ms determined from this experiment and from two others are shown in Table 2.

normal liver[14]. In contrast, addition *in vitro* of 50 μM adrenaline effected a fifteenfold increase in the basal activity as compared to a twofold increase in normal liver. No synergistic effect of GTP could be observed in the present study (Table 1) although such an effect is a well known phenomenon in normal liver[12,15]. Guanylyl imidodiphosphate, an analogue of GTP which is not a substrate for nucleotidases, was also ineffective, even at high concentration (0.1 mM). The relative fluoride response was, however, present in Zajdela hepatoma and even enhanced as compared to normal liver. These phenomena (that is, low basal activity, and lack of effect of guanyl nucleotides), are probably indicative of marked changes in the catalytic component of the cyclase system. These changes are associated with a drastic alteration in the nature of glucagon binding or in its efficiency.

In view of the unusual character of cyclase stimulation by adrenaline in Zajdela hepatoma, its mechanism was further studied. The effects of various agonists were tested in a dose–response fashion and each experiment was repeated at least three times with different cyclase preparations from the normal liver and Zadjela hepatoma. In normal liver, the relative order of potency of the various agonists tested was the following: protokylol>isoproterenol>adrenaline>noradrenaline (Fig. 1*a*). This corresponds to a typical β_2 receptor[16,17,18]; we obtained similar results with a purified plasma membranes preparation (unpublished data). It should be noted that protokylol (an analogue of isoproterenol characterised by a more hydrophobic substitution on the amino nitrogen), had an apparent K_m of 30 nM, and is the best β_2 agonist available in terms of affinity for the receptor. Similar results with this compound were reported previously by Rosen *et al.*[19] for the β_2 receptor of frog erythrocytes. In Zajdela hepatoma cells (Fig. 1*b*), the order of relative potency of the various agonists was quite different: isoproterenol>protokylol>noradrenaline>adrenaline; while the affinity of isoproterenol was not modified, adrenaline became less potent than noradrenaline and protokylol less than isoproterenol. This corresponds to a β_1 receptor[16,17]. The apparent K_m values for the various agonists were calculated in three different experiments and are listed in Table 2. The relative potency ratio (apparent K_m noradrenaline/apparent K_m adrenaline) was 4.8 for normal liver and 0.56 for Zajdela hepatoma. These ratios are similar to those reported by Burges and Blackburn for rat lung (β_2 receptor) and rat heart (β_1 receptor), namely 6.2 and 0.6 respectively[17]. In addition, we tested the effect of (−)-nordefrine, a relatively specific β_1 agonist[16]. Its apparent K_m was 5 μM in normal liver and 1 μM in Zajdela hepatoma. These values are similar to those found with noradrenaline (4.3 μM and 1.3 μM respectively). To confirm this observation, further experiments were performed using specific antagonists. Their effect on adenylate cyclase was determined in the presence of a concentration of isoproterenol (1 μM) which resulted in a submaximal response. We used butoxamine as a β_2 inhibitor[20] and practolol as a β_1 inhibitor[21]. In normal liver, the isoproterenol-stimulated cyclase was blocked by 0.1 mM butoxamine, whereas practolol, at the same concentration, was completely ineffective. In contrast, in Zajdela hepatoma, 10 μM practolol inhibited cyclase activity by more than 75%, whereas butoxamine was only slightly active at the same concentration.

It would seem, therefore, that in our system, malignant transformation not only provokes quantitative changes in the adenylate cyclase system, but is accompanied by a unique and hitherto undescribed qualitative change, namely the switch of the adrenoceptor from the normal β_2 type to the β_1 type. It should be noted that in the ascites hepatoma, the cyclase did not respond to unusual or inappropriate stimulating agents (for example, ACTH, dopamine, adenosine, serotonine). It is possible that the two different types of receptors coexist in liver and that the shift from a β_2 to a β_1 type corresponds to a change in the β_1/β_2 ratio. However, we favour the hypothesis that the catecholamine β

Table 2 Action of catecholamines on adenylate cyclase activity in normal liver and in Zajdela hepatoma

Agonist	Normal liver	Zadjela hepatoma
	Apparent K_m	
Protokylol	0.02 (0.03; 0.015; 0.015)	1.6 (2.5; 1.0; 1.3)
Isoproterenol	0.18 (0.20; 0.15; 0.20)	0.20 (0.37; 0.13; 0.17)
Adrenaline	0.9 (0.9; 1.0; 0.8)	2.3 (3.0; 1.6; 2.5)
Noradrenaline	4.3 (5.0; 5.0; 3.0)	1.3 (1.8; 1.0; 1.2)
	Relative potency	
Protokylol/isoproterenol	0.11	8
Noradrenaline/adrenaline	4.8	0.56

The apparent K_m is the concentration of agonist required to produce half maximal stimulation of adenylate cyclase. Results are the means of values from three experiments which were performed in a manner similar to that shown in Fig. 1; individual values are given in parentheses. Relative potency refers to the ratio of the apparent K_m of protokylol to that of isoproterenol, and of noradrenaline to that of adrenaline.

receptor constitutes a single entity susceptible to secondary, and possibly to reversible modification towards either type. Our results are the first demonstration of such a shift and seem consistent with recent data indicating a transformation between α and β receptors in certain physiological conditions[22,23].

Effect of restriction endonucleases on infectivity of Rous sarcoma virus DNA

TRANSFECTION and molecular hybridisation assays show that animal cells infected with RNA tumour viruses carry DNA copies of the viral genome integrated into their chromosomes (for review see ref. 1). The transfection assay in particular enables the direct demonstration of the biological activity of the viral DNA[2–4]. Shearing of the DNA[5] and fractionation in sucrose gradients[6] provided evidence that the virus is specified by DNA pieces of about 6×10^6. Transfection kinetics[5] and transfection probabilities at the endpoint dilution of the DNA[1,7] show that one DNA piece of that size is sufficient to accomplish transfection.

Excision and extraction of the integrated viral DNA from cellular chromosomes requires an enzyme that will digest the cellular but not viral DNA. Such a selective digestion could be accomplished with restriction endonucleases for which there are no cleavage sites in the viral DNA. In this report we show that an enzyme from *Anabaena variabilis* (*Ava*I) satisfies these criteria, for it cleaves the DNA of cells transformed with Rous sarcoma virus (RSV) without abolishing the infectivity of this DNA.

DNA preparations from chicken cells transformed with RSV were used throughout the experiments because their high infectivity affords a reproducible transfection assay[1]. One of these DNAs was extracted from a clone (No. 52) of cells derived (with all probability) from a single chicken embryo fibroblast infected and transformed with a single particle of the Schmidt–Ruppin RSV, subgroup D (SR-D) The origin of the virus and the cells, the cloning procedure and the extraction of the DNA have been described elsewhere[8]. In transfection assays, virtually all of the chicken cell cultures which received 5 μg of this DNA gave rise to a non-defective (*nd*) sarcoma virus (ref. 1 and J.H., and M.H., submitted for publication). Thus the DNA is named *nd*SR-D DNA. The other DNA used was extracted from mass cultures of chicken fibroblasts transformed with the same SR-D virus as before. In contrast to the first DNA, this preparation gave rise, following transfection, to both *nd* and transformation-defective (*td*) viruses[8] and therefore is called *nd,td*SR-D DNA. The dose–response relationships in transfection assays with these two DNA preparations have been described elsewhere[1], where it was also shown that *td* viruses arise uniquely from *td*RSV DNA.

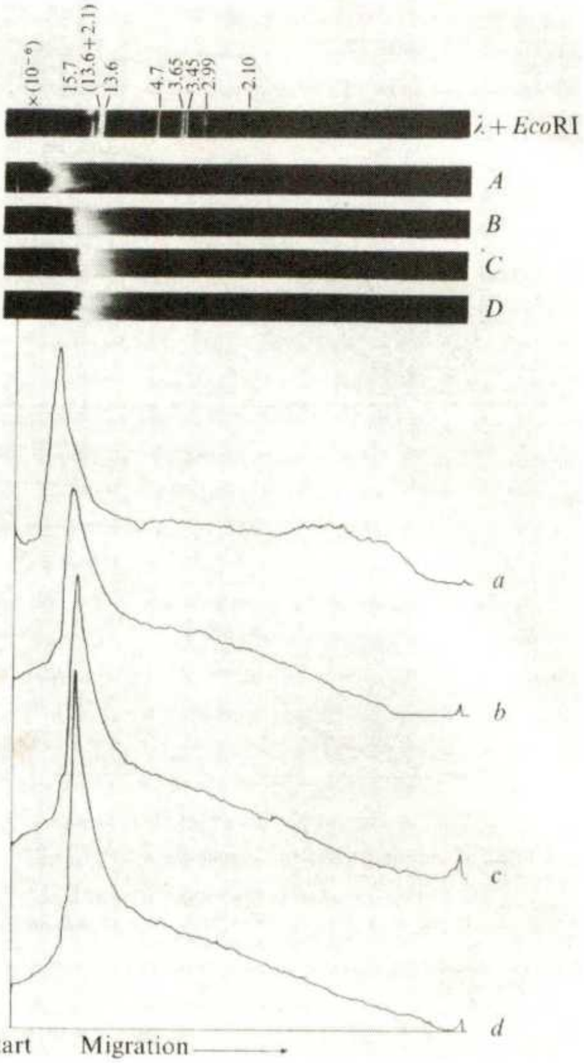

Fig. 1 Electrophoretic migration in 1% Agarose gels of phage λ DNA-*Eco*RI digest (λ+*Eco*RI), *nd,td*SR-D DNA (*A*), and *nd,td*SR-D DNA-*Ava*I digests (*B*, *C*, *D*). The *Eco*RI fragments of phage λ DNA were used as molecular weight markers. The *nd,td*SR-D DNA was either mock-digested for 9 h (*A*), or digested with *Ava*I endonuclease for 3 h (*B*), 6 h (*C*), and 9 h (*D*). The Joyce–Loebl densitometry tracings of *A*, *B*, *C*, and *D* are shown in *a*, *b*, *c*, and *d*, respectively.

The restriction endonucleases used in this study are listed in Table 1. Each enzyme was assayed by incubation with 1.5 μg of phage λ or SV40 DNA at 37 °C. Incubation times and references for the incubation conditions with different enzymes are given in Table 1. The DNA digests

Transfection assays were carried out by means of DEAE–dextran (experiment 1) or calcium phosphate (experiments 2 to 6) in conditions described in refs 8 and 10. Each culture received 5 μg of undigested or digested DNA. The DNAs were extracted from SR-D-transformed chicken cells and consequently contained both the cellular and viral DNA as described in the text. *Eco*RI and *Ava* enzymes were provided by Drs A. Bernardi and G Roizès, respectively The *Haemophilus* enzymes were purified according to the procedure described in ref. 21. Incubation conditions of the DNA with the respective restriction enzymes are given by references in the table.

*Number of transfected (that is, virus producing) cultures per number of DNA-treated cultures The transfected cultures are designed with *nd* or *td* to indicate that the DNA gave rise to a transforming or non-transforming virus, respectively.

†K. Murray, S. G. Hughes, J. S Brown, and S. Bruce, submitted for publication.

vere analysed by electrophoresis in 1% Agarose gels and he resulting bands, were, located under ultraviolet light after staining with ethidium bromide[9].

The DNA (15 μg) extracted from chicken cells transformed with SR-D was mixed with appropriate amounts of the restriction enzymes and incubated in the conditions used for the enzyme assays (see also Table 1), and the reactions stopped by addition of 0.1 volume of 0.1 M EDTA. Then the volume of the mixture was adjusted with 0.14 M NaCl–0.05 M, Tris-HCl, *p*H 7.4, or HEPES-buffered saline solution (NaCl, 8 0 g l^{-1}; KCl, 0.37 g l^{-1}; $Na_2HPO_4.2H_2O$, 0.125 g l^{-1}; dextrose, 0.1 g l^{-1}; *N*-2-hydroxyethylpiperazine-*N*-2-ethane sulphonic acid, 5.0 g l^{-1}, *p*H 7.05) to make 6 ml, and the mixture was distributed into three secondary chicken cell cultures to assay its infectivity by means of the DEAE-dextran[8] or calcium phosphate[10] techniques, respectively. The cultures were kept growing for about 3 weeks (through four to five passages) and examined for the occurrence of transformed cells and, in non-transformed cultures, by reverse transcriptase assay[11] for type C particles in the culture medium.

The results are summarised in Table 1. Of the eight restriction endonucleases, seven rendered the DNA non-infectious. This suggests that RSV DNA contains cleavage sites for the enzymes *Hin*dII, *Hin*dIII, *Hae*III, *Hpa*I, *Hpa*II, *Eco*RI, and *Ava*II. The alternative view that loss of infectivity results from the cleavage of cellular rather than viral DNA sequences is improbable because mechanical shearing of the DNA preparations down to the average size of 6×10^6 daltons does not abolish their infectivity[5-7] and unintegrated viral DNA obtained from mouse cells early after infection with a murine leukaemia virus is infectious[12] though this DNA presumably lacks cellular sequences.

The case of the eighth enzyme, *Ava*I, was different. The electrophoretic analysis (Fig. 1) showed that digestion with *Ava*I gave a continuous distribution of fragments in which no sharp bands were visible, but with a maximum abundance of fragments larger than 20×10^6 daltons (as determined from comparison with migration patterns of phage λ DNA-*Eco*RI digest[13]). It is worth adding that the migration pattern of the 3-h digest was essentially the same as those of 6-h and 9-h digests (Fig. 1). This indicates that virtually all the *Ava*I sites of the DNA were cleaved within 3 h of incubation. In transfection assays (Table 1) the DNA cleaved with *Ava*I repeatedly gave rise to the virus though with a somewhat lower efficiency than that obtained with undigested DNA *A priori* such a difference in transfection efficiency could be attributed to a diminished uptake by recipient cells of DNA molecules of smaller size rather than to the cleavage of certain, but not all, molecules of viral DNA by the *Ava*I restriction enzyme. The possibility of incomplete digestion of the DNA by the enzyme was eliminated in experiment 6 (Table 1) showing that the DNA infectivity resists much longer incubation times than that (3 h) sufficient for exhaustive cleavage (Fig. 1).

Table 1 also shows that both *nd* and *td* viruses were recovered following transfection with *nd,td*SR-D DNA that had been treated with *Ava*I. This hardly surprising observation implies that no *Ava*I cleavage site is formed when a *td* virus DNA is generated from RNA (or less likely (ref. 1 and J.H., and M.H, submitted for publication) DNA) of the non-defective parent.

In conclusion the transfection assays show that cleavage sites for *Hin*dII, *Hin*dIII, *Hae*III, *Hpa*I, *Hpa*II, *Eco*RI, and *Ava*II restriction endonucleases occur within SR-D DNA In contrast, both *nd* and *td* SR-D DNAs lack cleavage sites for *Ava*I endonuclease This offers the means for isolation of fragments of cellular DNA containing the integrated viral DNA and the analysis of cellular DNA sequences adjacent to the integrated viral genome.

The authors thank Dr A. Bernardi for *Eco*RI, and Dr G Roizès for *Ava*I and *Ava*II restriction enzymes. The phage λ DNA was kindly provided by Drs A. Bernardi and P. Tiollais. This work was supported in part by the CNRS and by the University Paris-Sud.

Spontaneous transformation of human skin fibroblasts derived from neoplastic patients

IN the past 15 years a considerable amount of data has been published showing that normal human fibroblasts have a finite division potential when cultured *in vitro*[1,2]. We have described the spontaneous establishment *in vitro* of stromal fibroblasts derived from human lung cancers[3], but it was difficult to know whether the proliferating fibroblasts were normal stromal cells or tumour cells. Therefore we decided to culture the fibroblasts from the skin of patients with lung tumours to see whether they had the same fate *in vitro* Here we describe the spontaneous transformation of skin fibroblasts derived from four neoplastic patients.

Skin biopsies from four cancer patients were obtained from the edge of the marginal wounds at the beginning of the operation. Three of these patients had lung cancer and one had a solitary plasmocytoma of the mediastinum. At the time of the biopsy the patients had not been on chemo- or radiotherapy Tissue samples were cut into small pieces with fine forceps and four to five fragments were placed into 30-ml plastic flasks. Each fragment was covered with a drop of medium and incubated in 90% air : 10% CO_2 at 37 °C. After 24 h, 5 ml of medium was added to each flask. When the fibroblast outgrowth covered the surface of the culture vessels, the cells were detached with a trypsin-versene solution and transferred into two new flasks (1 : 2 split). Cultures were then subcultured routinely with 1 : 2 splits when the cells were confluent. The medium used throughout was Eagle's MEM supplemented with non-essential amino acids, 15% foetal calf serum, penicillin (100 U ml^{-1}) and streptomycin (100 $\mu g\ ml^{-1}$) Control cultures from thoracic skin biopsies of sex-matched but not age-matched normal donors were initiated and continued in the same conditions.

During the first five subcultures the cells from the cancer patients looked like normal fibroblasts disposed in orderly arrays. Between the sixth and the ninth passage, foci of epithelial-like cells began to appear. The latter progressively invaded the cultures, forming a criss-cross pattern with multilayering and random orientation. Cytogenetic analysis, performed at different passages (summarised in Table 1) showed that in all cultures derived from the skin of patients with lung tumours, an abnormal chromosome distribution appeared during the early phases of culture, contrasting with the near normal distribution found in the control skin fibroblasts and in WI-38 cells[4].

The colony-forming capacity in a semi-solid agar medium was also checked[5]. Fibroblasts from normal donors did not form colonies The cells from the patients, however, gave rise to more than 0.5% colonies. The cultures derived from donors with lung tumours were also found to form aggregates in the presence of concanavalin A[6] whereas the control cultures did not. From each culture derived from the patients it was possible to obtain cells which overcame phase III (ref. 1) and became established.

All cultures derived from normal donors went through the normal evolution previously reported[1,2] and died after serial subculture. Finally we should emphasise that when the fibroblasts were derived from skin explants and adapted to *in vitro* culture, and when transformation occurred, our laboratory contained no HeLa cells or other cell lines, which could have been sources of contamination.

Our results show that it is possible to obtain spontaneous transformation in cultures obtained from the skin biopsies

Table 1 Number of mitoses with different sets of chromosomes found in human fibroblasts cultivated from the skin of normal donors and from patients with lung tumours

†Number of passages after transformation has occurred.

of patients with lung tumours. Transformation is characterised by an abnormal ploidy, a capacity to form colonies in a semi-solid agar medium, the formation of foci of piling up cells among the monolayers and the acquisition of an infinite life span. For the moment it is impossible to know if the transformed cells originated from skin fibroblasts or from tumour cells disseminated in the skin of the patients.

We thank Dr Alvaro Macieira-Coelho for critical revision of our manuscript.

Enumeration of specific cytotoxic T cells

EFFORTS directed towards the enumeration of effector cells involved in the cell-mediated immune response have so far met with little success. One of the principal reasons for this failure is the current ignorance of relationships between killer, lymphokine producer and suppressor T cells, all of which have effector functions. To date, attempts at quantification have focused principally on cytolytically active (killer) T cells largely because *in vitro* assays using target cells labelled with radioisotopes afford sensitive and reproducible measurement of their function[1].

Two factors have, however, hampered the enumeration of the killer cells in cytolytically-active lymphoid cell populations: (1) the effector T cell can kill more than one target cell[2,3] and (2) the number of effector cells cannot be distinguished from their intrinsic lytic efficiency. The latter factor is presumably a complex function comprising the mobility of effector cells, their avidity for target cells and their ability to lyse and disengage from targets. Standard assay conditions for *in vitro* cytotoxicity enable comparisons to be made between the lytic activities of different "immune" lymphoid cell populations, but these comparisons may bear little relation to the relative numbers of effector cells if there is wide variation in killing efficiency. We describe here an experimental approach in which efficiency is maximised and the number of cytolytically-active T cells within a lymphocyte population is determined by preventing killer cells from lysing more than one target.

The method was based on two findings: (1) Lymphocyte–target cell interactions take place in the presence of Mg^{2+}, but in the absence of Ca^{2+} these lessions do not lead to cytolysis[4]. (2) Cytochalasin A inhibits cytolysis (irreversibly) and does so by interfering with a stage in the lytic cycle which precedes the Ca^{2+}-dependent event(s). (It seems likely that cytochalasin A inhibits lymphocyte–target cell interactions, as does its congener cytochalasin B (ref. 5), although the validity of this assumption is unnecessary for the arguments which follow.)

Table 1 Maximising the interaction between effector and target cells

Target cells added (× 10^{-3})	Target cells killed (× 10^{-3})	
	3 h	5 h
25	2.8+0.1	2 8±0 2
50	3 6±0.3	3.8±0.3
100	3.7±0 5	3 6±0.4
200	3 6±0.7	4.0±0 5

Spleen cells (5 × 10^5) from sensitised animals were incubated with the indicated number of ^{51}Cr-labelled P815 target cells as described in Fig. 1. After 1 h at 37 °C, cytochalasin A was added and 10 min thereafter Ca^{2+}-containing medium The number of target cells specifically lysed (± s e m. for duplicates) was determined 3 and 5 h after the addition of Ca^{2+}—containing medium to show that maximum lysis had occurred.

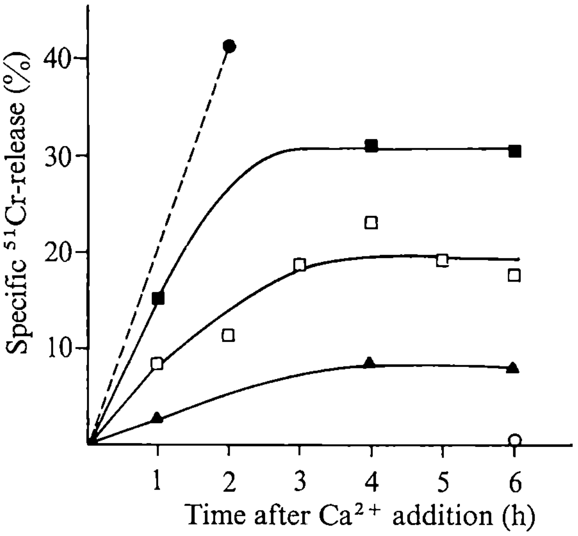

Fig. 1 Spleen and ^{51}Cr-labelled tumour cells were washed twice in Ca^{2+}-free medium (MEM-suspension, Microbiological Ass., containing 5 × 10^{-5} M EDTA to remove trace amounts of Ca^{2+}, and 5% dialysed foetal calf serum) just before use. Spleen (50 µl) and target cells (50 µl, 10 × 10^3) were added to conical-well microtitre plates which were centrifuged for 1 min (1,000 r p.m. No. 276 International Centrifuge rotor, 22 °C) and incubated for 1 h at 37 °C. Cytochalasin A (50 µl, 30 µg ml^{-1}, Aldrich; the stock solution, 10 mg ml^{-1} in dimethyl sulphoxide, was diluted with Ca^{2-}-free medium before use) was then added, followed 10 min later by 100 µl Ca^{2+}-containing medium (MEM–Earle's Salts, Microbiological Ass., containing 5% foetal calf serum). The specific release was calculated as follows:

$$\text{Specific release} = \frac{\text{Experimental c.p m.} - \text{control c p m.}}{(0.8) \times (\text{incorporated c.p.m.})}$$

where 0.8 is the fraction of the incorporated ^{51}Cr which is releasable by hypotonic lysis. The controls were spleen cells from uninjected C57BL/6 mice treated identically to the "immune" cells. The control release was 5% per h for all conditions. The following numbers of spleen cells were used: ▲, 2.5 × 10^5; □, 5 × 10^5; ■, 10 × 10^5; ●, 5 × 10^5 (no cytochalasin A was added); ○, 5 × 10^5 (no Ca^{2+}-containing medium was added).

Thus, by incubating lymphocytes with target cells in a medium containing Mg^{2+} but not Ca^{2+}, interactions occur which do not lead to lysis. If Ca^{2+} is added to such cultures together with cytochalasin A, those target cells which have functionally engaged with effector cells during the preincubation period will go on to lyse. The presence of cytochalasin A will, however, prevent any new interactions from proceeding to a Ca^{2+}-dependent stage, and thus new liaisons formed after the addition of Ca^{2+} will not lead to lysis. Assuming each effector cell becomes bound to one target cell during the preincubation period, the subsequent number of target cells which lyse when Ca^{2+} is added to the cultures is equivalent to the number of effector cells present.

Cytolytically active lymphoid cell populations were generated by immunising adult C57BL/6 mice (Jackson Laboratories) with a mouse mastocytoma (P815-X2) of the DBA/2 strain. Ten million P815 cells were given intraperitoneally and the lymphoid cell populations collected 10–12 d later in a manner previously described in detail[1,6]. The cell-mediated destruction of P815 cells in this system has been shown to be exclusively due to T cells[7].

Specific cytolysis was totally inhibited when lymphocytes

Table 2 Specific cytolysis as a function of interaction time in Ca^{2+}-free medium

Ca^{2+}-free incubation time before cytochalasin addition (minutes)	% Specific Lysis 3 h	5 h
0	0.0±0.1	0.0±0.1
30	20.5±0.1	21.0±0.2
60	23.0±0.2	23.5±0.1
120	22.5±0.1	25.0±0.1

Spleen cells (1×10^6) from sensitised animals and ^{51}Cr-labelled P815 target cells (2×10^4) were mixed in conical-well microtitre plates and centrifuged as described in Fig 1 After the incubation times indicated cytochalasin A was added and 10 min thereafter Ca^{2+}-containing medium. The percentage-specific lysis (± s e m for duplicates) was determined 3 and 5 h after the addition of Ca^{2+}-containing medium

and target cells were incubated in the presence of 3 $\mu g\ ml^{-1}$ (6×10^{-6} M) cytochalasin A Lymphoid cells preincubated for 10 min with cytochalasin A and then washed did not recover their lytic activity, but target cells treated in an identical manner were as susceptible to lysis as untreated cells (data not shown). The drug did not increase the rate of spontaneous release of ^{51}Cr from target cells (5, confirmed in experiments not shown).

The experimental protocol used to enumerate effector T cells is given in detail in Fig 1 (Cytochalasin A was added 10 min before Ca^{2+} to allow a finite time for the drug to exert its effect.) No cytolysis occurred when lymphocytes were incubated with target cells in a medium containing Mg^{2+} but not Ca^{2+} (Fig. 1). On the addition of Ca^{2+}, however, ^{51}Cr release readily occurred (Fig. 1). Two features of the target cell destruction following the addition of Ca^{2+} should be noted. (1) The number of target cells killed was proportional to the number of spleen cells present in the culture; (2) a period of about 3 h in medium containing Ca^{2+} was necessary to allow maximal ^{51}Cr release. To assure that the drug was effective and that the maximal ^{51}Cr release had occurred, lysis was determined 3 and 5 h after the addition of Ca^{2+} in the presence and absence of cytochalasin A.

If, as is our contention, the maximal amount of target cell destruction depicted in Fig. 1 is equivalent to the number of effector cells present in the lymphocyte population, several provisions must hold. First, for a given effector cell population, the maximum specific target cell destruction after the addition of Ca^{2+} to the cultures, should be directly proportional to the number of lymphocytes present. The data in Fig. 1 show this to be the case. Second, increasing the size of the target cell pool, above the minimum required to engage all effector cells, should not further increase the number of target cells killed. When 5×10^5 immune spleen cells were incubated with between 5×10^4 and 20×10^4 target cells, the number of target cells killed after the addition of Ca^{2+} was constant (Table 1) Third, the number of target cells killed should not be increased if the incubation period in Ca^{2+}-free medium is extended (that is, a maximal number of interactions had occurred in the preincubation time chosen). The number of functional engagements between lymphocyte and target cell did not significantly increase over the period 30 min to 2 h (Table 2), in keeping with previous studies[2,8].

Table 3 Frequency of specific cytolytic T cells in the spleens of alloimmunised mice

Experiment	Days after immunisation	Maximum number ($\times10^{-3}$) of target cells lysed per 5×10^5 viable cells	Frequency of effector cells (%)
1	10	11.0	2.2
2	10	9.0	1.8
3	10	7.0	1.4
4	10	5.0	1.0
5	10	3.5	0.7
6	11	8.0	1.6
7	11	6.0	1.2
8	11	4.5	0.9
9	12	4.0	0.8
10	12	4.0	0.8

The number of effector cells in each spleen cell suspension was determined using the experimental approach given in Table 2 Three spleens were pooled in each experiment

$$\text{Frequency} = \frac{\text{maximum number of target cells killed}}{5\times10^5\ \text{spleen cells}}$$

Since these criteria were fulfilled, the number of target cells maximally killed was equated with the number of effector cells. This approach was used on several occasions to enumerate effector cells in C57BL/6 spleen cell populations at the peak of the primary immune response (10–12 d) after immunisation with P815 cells. Table 3 shows that at this time between 0.7 and 2.2% of the total spleen cell population was specific anti-P815 T effector cells.

There are two principal assumptions necessary in order for our calculations to be valid. First, all effector cells must functionally interact with a target cell during the preincubation period (obviously if some effector cells do not engage a target cell the number of effector cells calculated will be an underestimate), and second, each effector cell must not functionally engage more than one target during incubation in the Ca^{2+}-free medium (or else the calculated value would be an overestimate of the effector cell incidence).

The first of the above assumptions seems warranted, for preincubation times between 30–120 min lead to the same amount of lysis following the addition of cytochalasin A and Ca^{2+} (Table 2). Indeed, in another experiment (not shown), there was no difference in the subsequent ^{51}Cr release whether cytochalasin A was added after 5 or 120 min. In all cases, however, cytochalasin A added at the same time as the target cells completely inhibited cytolysis. It would thus seem, in keeping with previous observations[8,9,11], that functional engagements between lymphocyte and target cell occur rapidly, and, in the conditions used in this study, are complete within 30 min.

The same arguments would seem to dictate that an effector cell does not functionally engage more than one target cell during the preincubation period. If that were the case, then extending the preincubation period would be expected to increase the number of such engagements. In fact, as earlier indicated (Table 2), preincubation periods between 30 and 120 min showed an identical number of functional interactions. It would seem unlikely that an effector cell undergoes multiple non-lytic interactions in the period 0–30 min but not thereafter, although admittedly this remains a faint possibility. It is also not likely that each effector engages several target cells simultaneously, for if this were the case, increasing the size of the target cell pool would increase the likelihood of such interactions. As Table 2 shows, however, lysis reaches a constant value not a constantly increasing one. Furthermore, extensive kinetic analysis of target cell death in ^{51}Cr-release killer assays provide evidence for "single hit" mechanisms of cytolysis[6].

Two methods of estimating effector cells have been used previously. One approach has been to equate the frequency of cytolytic T cells with the number of target cells specifically lysed in the presence of a great excess of target cells[6,10]. The possibility of the effector cells recycling (that is, that one lymphocyte kills more than one target cell) was largely ignored in those studies, and it is therefore likely that the calculated frequencies were overestimates Indeed, Henney[6] reported the incidence of effector cells in the system reevaluated here as approximately 4% of splenic lymphocytes, a number 2–3 times higher than the incidence estimated in the present study.

The frequency of cytolytically-active cells has also been measured by counting those lymphocytes which adhere to target cells[3,8,11]. The critical assumption in this approach is that each lymphocyte which binds to a target cell is a specific effector cell. This is almost certainly not the case; indeed, both precursor[12] and memory cells[13] have been shown to have affinity for homologous allogeneic cells, but neither of these T-cell populations are cytolytic[13,14]. The contribution of non-cytotoxic lymphocytes to the overall frequency of target-binding cells remains to be established.

We have thus described a novel method for calculating the incidence of specific cytolytically active T cells. The procedure used here measures only killer T cells and obviates the deficiencies of previous approaches to this problem by preventing the effector cell from 'recycling'. Obviously the enumeration of cytolytically-active T cells provides only a partial quantification of the overall cell-mediated immune response. The quantitative relationship between this T-cell compartment and those producing lymphokines, memory and regulator cells remains to be evaluated.

Enhancement of delayed hypersensitivity by depletion of suppressor T cells with cyclophosphamide in mice

THE delayed hypersensitivity (DH) reaction seems to be enhanced by treatment with cyclophosphamide and this has been discussed in the context of depression of antibody production[1-4]. Askenase *et al*[5], however, reported that low doses of cyclophosphamide augmented the reaction to sheep erythrocytes without affecting antibody production. Polak and Turk[6] suggested that cyclophosphamide could break down immunological tolerance to the dinitrophenyl group, as measured by a skin reaction in guinea pigs after treatment with the drug to inhibit suppressor cells. The nature of the suppressing cells was not clear at the time. We report here that treatment of mice with cyclophosphamide also significantly affects DH reaction to methylated human serum albumin (MHSA)[7] which induces little antibody production, and that the enhanced DH reaction is caused by damage to T rather than B cells. Independent recovery, from the damage due to cyclophosphamide, by individual subpopulations of T cells accounts for the kinetics of this phenomenon.

Table 2 Suppressive effect of transferred lymphoid cells on enhanced DH to MHSA in mice treated with cyclophosphamide

Cyclophosphamide treatment	Cells transferred	No. of animals	DH on day 12
150 mg kg^{-1}	None	3	10.7±1.9
150 mg kg^{-1}	5×10^7 Spleen cells	4	9.3±1.5
150 mg kg^{-1}	2×10^7 Thymus cells	4	6.3±2.5
None	None	4	5.3±1.8

Male C57BL/6 mice (age 4 months) were given an intraperitoneal injection of cyclophosphamide (150 mg kg^{-1}) 4 d before sensitisation, and an intravenous transfer of spleen or thymus cells 2 d later.

Male C57BL/6 and (C57BL/6×CBA)F$_1$ mice aged 4 or 6 months were used : they seem to be high DH responders[8]. Animals were sensitised by an injection, into the left footpad, of an emulsion (0.05 ml) consisting of equal amounts of MHSA solution (5 mg ml^{-1} in saline) and Freund's complete adjuvant (3 mg of dead H$_{37}$R$_V$ tubercle bacilli per ml). A challenge injection of 0.02 ml of MHSA solution (1 mg ml^{-1}) was given into the right footpad on day 12 of sensitisation, as the optimal DH response was obtained by this method. Swelling of the right footpad was measured both immediately before and 24 h after the challenge, and the difference between two measurements in a thickness of 0.1 mm was used to describe the intensity of the DH response[9]. Mice received an intraperitoneal injection of cyclophosphamide (given by Shionogi Co., Osaka, 15 or 150 mg per kg body weight) at intervals before or after sensitisation, as indicated in Tables 1–3. Spleens and thymuses were removed from normal syngeneic male mice and the cells from them were suspended in and washed three times with RPMI-1640 medium. Appropriate numbers of these cells were transferred into the retro-ocular plexus of the cyclophosphamide-treated mice.

Table 1 shows the effects of cyclophosphamide on the DH response to MHSA when the drug was given 8 d or 1 d before sensitisation. There was marked enhancement of DH

Table 1 Effect of cyclophosphamide on DH to MHSA in mice

Cyclophosphamide treatment	Interval between treatment and sensitisation	No. of animals	DH on day 12*	Thymus weight (mg)
None	—	4	5.3±1.8	29±4
150 mg kg^{-1}	1	5	16.4±1.2	23±6 [14]†
	8	5	17.0±6.3	38±6 [21]†
15 mg kg^{-1}	1	5	7.5±1.5	35±9 [14]†
	8	5	9.0±4.2	35±4 [21]†

Male C57BL/6 mice (age 4 months) were given an intraperitoneal injection of cyclophosphamide (15 or 150 mg kg^{-1}) at various intervals before sensitisation.
*Each value represents mean ± s.e. (0.1 mm).
†Interval between treatment with cyclophosphamide and measurement.

Table 3 Effect of cyclophosphamide on effector cells in DH to MHSA in mice

Cyclophosphamide treatment	Interval between sensitisation and treatment	No. of animals	DH on day 12	Thymus weight (mg)
None	—	3	15.2±2.9	32±8
150 mg kg^{-1}	4	4	2.8±0.9	14±2 [9]*
	9	4	1.0±0.4	14±2 [4]*

Male (C57BL/6 × CBA)F$_1$ mice (age 6 months) were given an intraperitoneal injection of cyclophosphamide (150 mg kg^{-1}) 4 or 9 d after sensitisation.
*Interval between treatment with cyclophosphamide and measurement

response in animals treated with the large dose. Table 2 shows that transfer of 2×10^7 thymus cells from untreated mice almost eliminated the DH enhancing effect. Transplantation of 5×10^7 normal spleen cells did not influence the enhanced DH significantly. These observations suggest that the DH to MHSA in mice is enhanced because cyclophosphamide damages suppressive T cells in the immune regulatory systems.

Table 3 shows that administration of cyclophosphamide after sensitisation suppresses the DH response. A minimal response appeared only in the group treated with cyclophosphamide on day 4 after sensitisation. These results indicate that effector T cells which are responsible for DH are also sensitive to cyclophosphamide There have been several reports of the inhibitory effect of the drug on DH responses[10], and Kerckhaert *et al.*[11] demonstrated the sensitivity of effector T cells. In experiments not described in Tables 1–3 we observed that previous treatment of mice with cyclophosphamide was not necessary for DH enhancement, and that treatment after sensitisation (such as in Table 3) could enhance DH only if the interval between treatment and challenge injection was sufficiently long, for example 12 d. We further observed that when the interval was just 9 d, DH was neither suppressed nor enhanced. This result together with our previous finding[12] that significant DH to MHSA was obtained as early as 4 d after sensitisation, suggest that the effector T cells, once affected by cyclophosphamide, recover sufficiently to generate significant DH response after about 5 d. This seems to be consistent with previous observations[2,11]. The 13-d or 20-d interval between treatment with cyclophosphamide and challenge injection (Table 1) might be long enough for the effector cells recovering from the damage to be sensitised with the antigen retained at the site of injection This may explain the apparent resistance of effector T cells to cyclophosphamide in this and some previous experiments[6].

Thymus weight did not recover significantly until 9 d after treatment (Table 3), and then recovered considerably on day 14 and rebounded on day 21 (150 mg kg^{-1}, Table 1). Recovered lymphoid cells were histologically detectable in the cortex on day 9 after treatment, but were hardly detectable on day 4. This seems to be consistent with other observations[10,13], and probably supports the suggested recovery of effector T cells. But the sites recovering cells remain unknown.

The recovery of suppressor T cells is probably delayed more than that of effector cells, and seems to be within 4 weeks (unpublished observations). In previous experiments[14] concerned with suppressor T cells, we found that thymus cells transferred into old recipients, which showed a maximal DH response, suppressed the development of DH to MHSA When transfer was into young recipients who developed moderate DH to MHSA, suppression of DH was not observed. Studies on the influence of whole-body irradiation[8] or adult thymectomy[14] confirmed this, and suppressor T cells seemed to be in the category of short lived T cells Because of a greater delay in recovery of suppressor T cells than of effector T cells after cyclophosphamide-induced damage, the regulatory activity of the suppressors on the effectors could be minimised, resulting in an increased DH response.

Cyclophosphamide has generally been considered to have a selective suppressive effect on the B-cell functions in some circumstances. This is supported by various phenomena including suppression of antibody production[1], proportional decrease in non-θ-bearing lymphocytes[15] and cell depletion in the non-thymus-dependent areas of lymphoid tissue[13,16], and so on[10]. Suppression of antibody production is often accompanied by an increase in DH response. This may indicate regulation of DH by antibodies[2,3].

In contrast, we conclude that T cells as well as B cells are remarkably sensitive to cyclophosphamide and therefore both DH and antibody production are defective immediately after treatment. Time for recovery from the damage is different between T cell subpopulations, that is, long-lived effector cells and short-lived suppressor or regulatory cells The former seem to recover more promptly than the latter. We suggest that this causes enhanced DH to MHSA in mice treated with cyclophosphamide. But the possibility remains that the suppression of DH by cyclophosphamide after sensitisation is due, at least in part, to damage to bone marrow-derived monocytes rather than, or in addition to, that of sensitised effector T cells.

We thank Professors K. Yasuhira and T. Teramatsu for advice.

Is the world getting naughtier?

CONSIDER the following statements:

Military expenditure by Persian Gulf states has risen fivefold in real terms between 1971 and 1975

In the past 25 years more than 13,000 tanks have been delivered to Middle Eastern countries

By the year 1980 the world will be producing 80,000 kilograms of plutonium annually (8 kilograms is enough to make one nuclear weapon).

The People's Republic of China now seems to be launching satellites for military reconnaissance purposes.

About 125,000 scientists and engineers in the United States work on military research and development.

They are just a few of the pieces of information that make up the as-ever impressive compilation of military statistics put out by the Stockholm International Peace Research Institute (SIPRI) in its annual yearbook *World Armaments and Disarmament* (MIT Press and Almqvist & Wiksell; SKr 106). For nearly 10 years now the world has been in SIPRI's debt for providing an endless stream of hard and almost-hard facts on military matters all around the world. It is, of course, difficult to judge what impact this impartial reporting has had on public opinion and political thinking (particularly difficult in the United Kingdom where government is distinctly exclusive and as a consequence public opinion is poorly developed on all defence matters). But the global impact has not been negligible and we must hope that the Swedish government never loses its resolve to continue to support SIPRI.

That said, it must be noted that the character of SIPRI, at least as seen through its yearbook, continues to change (as we have reported on a couple of occasions previously). More and more are personal opinions being expressed in the commentaries. Words like "bonanza", "enormity", "seemingly endless", "frightening prospect" and so on crop up increasingly often. The world as seen by SIPRI seems to be getting continually more naughty and fractious. Of course, there are good grounds for showing concern, particularly at the way in which the Third World is picking up military momentum. But there are three reasons why we believe that SIPRI should steer clear of expressing views.

First, if it can't be detached and neutral, no-one else can. There are plenty of committed institutions around the world—committed to the environment, world government, disarmament and so on. SIPRI's strength has always been its detachment; others might use its figures in any way they choose but it would simply report. Although there is much populist appeal in the path it now seems to be treading, one suspects there is less respect from the hard-headed in the armament and disarmament community.

Second, although there is really no suggestion at all that SIPRI's figures are influenced by its views, there is a risk that the sort of things it will pay attention to could be so affected. Various forms of environmental warfare are discussed in the yearbook, for instance. For example, it is suggested that the ionosphere–Earth wave guide could be used to generate very low frequency electromagnetic fields to couple into people's alpha rhythms. "If methods could be devised to produce greater field strengths . . . either by natural (for example, lightning) or artificial means, then it may become hypothetically possible to impair the performance of a large group of people in selected regions over extended periods." Now this is the idlest of coffee-table musing with, at first sight, the severest of physical objections to be laid against it. Is it right that SIPRI, in its yearbook, should be mixing such vague ideas with its strong brew of hard facts?

Third, the news is not always as bad as SIPRI makes out. "The arms race between the two great powers continued unabated", says SIPRI. But in real terms, military expenditure in the Soviet Union has held roughly constant since 1968 and in the United States has declined in the same period by more than a quarter (aided, of course, by the withdrawal from Vietnam). The world total of annual military expenditures (which includes burgeoning Middle East figures) has remained on a plateau of 210,000 million US dollars (at 1970 prices) for seven years now, and as a percentage of gross domestic product has accordingly declined steadily. It goes without saying that this is a frightening sum of money, but with growing complexity and thus cost of armaments, constant expenditure means less commitment. SIPRI's own figures seem open to more optimistic interpretations □

Towards an environmental ethic

How should decisions concerning the environment be made? Eric Ashby, examining recent work on the subject, offers his view

IN 1961 there was published in Washington a report under the modest title House Document 522. It ran to eleven volumes. It was prepared by the American Army Corps of Engineers. Its theme was a Comprehensive Survey of the Water Resources of the Delaware Basin. The report recommended that a dam should be built on the Delaware River at a place called Tocks Island in New Jersey. The dam would create a lake about 37 miles long. The estimated cost (when it was reviewed at 1975 prices) was about $400 millions.

House Document 522 includes a massive exercise in cost-benefit analysis. The recommendation to build a dam rested on four arguments: to diminish the danger of floods downstream; to provide a water reserve in case of drought; to run a hydro-electric power plant; and to create a recreation area of 72,000 acres which would attract (according to the first estimate) as many as 9 million visitors a year. These potential visitors were regarded as a substantial "benefit" in the cost-benefit analysis, on the assumption that they would be worth $1.35 per person per recreation day.

Of course the proposal generated massive opposition. Some of the quantified values were challenged, but the most powerful arguments against the proposal rested on unquantified values: desecration of the last free flowing river in the east of the USA; acres of wilderness alienated for roads and parking lots and motels; the plea that this beautiful part of the river should be treated as an endangered species. It is a debate familiar to us in Britain. We had something like it over the Cow Green reservoir in Upper Teesdale in the 1960s.

The dam is not yet built, nor at present is it likely to be built. But the fifteen-year-long controversy over it has produced one admirable and important second order consequence. It prompted the American Academy of Arts and Sciences to sponsor a study of the problems of decision-making about the environment. The prime problem is how to incorporate what the study calls "fragile" values into the "hard" values which can reasonably be quantified. For over four years a group including lawyers, scientists and philosophers have reflected on this issue. Their conclusions are now issued in a book[*] which is, I believe, the first serious and authoritative work on the philosophy of environmental protection. Its starting point is the Tocks Island controversy, which is going to be treated intensively in a second volume to be added to this study[†] But the reflections go far beyond that specific episode. In essays, all of which are careful and one or two of which are brilliant, the nine authors set out their attitudes to the conflict of values which is the inevitable dilemma facing those who have to make decisions about the exploitation of the environment by man.

The impressive feature of the book is that it does not reach a consensus; it does not offer formulae for decision-makers. Its authors have the courage to declare that there is no simple resolution to the question: how do you reconcile the protection of nature with the needs of industrial man? It eschews slick and glossy utopias. It was J. S. Mill who wrote that the test of good government is the degree to which it increases the sum of good qualities in the governed. All the authors agree that there are values about the environment which are "good" and values which are "bad". But, as Robert Dorfman writes in the last essay, "I do not believe that those questions can be answered definitely, now or ever; but neither can they be ignored. The progress that I see in our project is that it points the way to living honestly with these forever open questions".

In Britain those who make decisions about the environment are no longer philistines. The main difficulty about "soft" or "fragile" values is not that they are neglected in the decision-making process; it is, as Harvey Brooks writes, "bringing them into a common intellectual framework with the rest of the analysis" for the purpose of political decisions, where "hard" quantified data based on cost-benefit analysis is likely to be more easily accepted. One of the redeeming features of the consumer society which has to be put in the balance against its many ugly features is that "fragile" values do play an increasingly important part in political decisions about the environment. In the files of the Department of the Environment there are many examples of planning permissions being refused because unquantified values were deemed to carry greater weight than quantified ones

This is encouraging, but it does not dispose of the difficulties which arise when there is a conflict of values, a clash of "goods" and the necessity to make a choice between them. The American Academy has put us all in its debt by facing these difficulties head on, in the book the Academy has sponsored. Among the issues discussed in the book, two seem to me to be particularly important.

- Values can be compared more easily if they can all be expressed in the same units. Does this justify the attachment of a money-tag to all values, even though this means what economists call "shadow pricing" (for example, the "value" of a view of the South Downs is the extra cost of not defacing the view if a road or a line of electric pylons has to be built in the neighbourhood)? Or are the values themselves distorted as soon as you try to put a money-tag on them?
- Is it possible to declare certain clear ends or goals in environmental policy, and to accept these ends as "given"–"axiom values", as it were—so that all decisions about the environment become means toward unalterable values which are the ends?

In a closely argued and subtle essay, Laurence Tribe tackles both these issues He dismisses one common criticism of cost-benefit analysis of environmental problems: the criticism that to quantify "fragile" values (a view, a rare plant community, a river in its natural state) is *illogical.* All such concerns "can in theory be incorporated into a rigorous analysis . . ." The danger of incorporating them, of putting price tags on elusive externalities, is more subtle. It is twofold. First, it flattens any sense of obligation toward natural objects into an aspect of self interest ("What is its money value to *me*?"). Second, it exerts "an enormous reductionist pressure on all values that would otherwise seem incommensurable with a calculus of human wants." In other words, the very translation of the values into manageable units may deprive them of their significance. Tribe's essay, and others in the book, particularly the essay by Harvey Brooks, are a great encouragement to the decision-maker when he is presented with a tidy and misleadingly comprehensive assessment of some project which will have an impact on the environment, neatly distilled into cost-benefit equations The decisions he has to make, writes Harvey Brooks, "are fundamentally political in the sense that they ultimately involve competing or conflicting values, and therefore cannot be resolved by purely 'rational' (that is, empirical and logical-deductive) means."

---

[*] Tribe, L H , Schelling, C. S , and Voss, J (Eds) *When Values Conflict* (Ballinger, Cambridge, Mass., 1976) To be published in the UK by Wiley.

[†] Feiverson, H. A , Sinden, F. W., and Socolow, R H (Eds.) *Boundaries of Analysis* (Ballinger, Cambridge, Mass , 1976) To be published in the UK by Wiley.

If this view is accepted, there remains the problem of how values are to be incorporated into analysis if they cannot be quantified, or related to self interest. To the question "Does nature embody values apart from its usefulness in serving man's desires?", the answer seems to be, "Yes, but we are not clear, and cannot expect ever to be clear, what these values are." So Laurence Tribe proposes a fresh attitude to this issue. He concedes that most people are very vague about the values they hold on environmental matters and that "such inchoate values are crystallised into distinct preferences or criteria of choice only through the concrete process of seeking means to attain them and gradually discovering what such means entail." In other words, values evolve through the choices made in groping toward them, and it is an essential aspect of freedom that we can choose what we shall value.

The direction in which this argument leads is as follows. First, there are no sanctified principles upon which environmental decisions rest, no "axiom values"; but all decisions are rationalised in some provisionally held principles, and these provisionally held principles *evolve* in the light of the choices which are made and the observed consequences of these choices. (Consider, for instance, how our values about pesticides have evolved through experience of making decisions about the use of pesticides.) Second, the direction in which principles evolve in our attitude toward the environment is taking us beyond the crude criterion of self interest—witness the recent legislation in Britain to protect some species of wild animals and plants, so rare that not one in a hundred of the legislators is likely ever to have seen any of them! It is this sort of argument which leads Laurence Tribe to suggest that social values about environmental issues progress in a spiral (their direction depending upon their position in the spiral; a framework for choice, as he calls it, which "must incorporate procedures for its own evolution.") And as a starting point on the spiral, Tribe suggests that we "should avoid a premise of human domination—or indeed a premise of the total subservience of any form of being to any other."

A feeling of obligation toward organisms other than man and a responsibility for protecting natural objects—valleys, forests, wildernesses—is of course no novelty among individuals. It is the codification of this obligation or responsibility which is novel. Nearly ten years ago, for instance, there was a planning enquiry into the effect which a North Sea Gas terminal would have on an area of natural beauty on the Norfolk coast. It was the Minister of Housing and Local Government who had to decide whether the area of natural beauty would be damaged by the siting of the gas terminal. In a word, he had to act as the "guardian" of the area of natural beauty. This attitude to a natural object prompts one to ask whether natural objects, trees and woodlands, creatures other than man, should have "rights". At first sight this seems to be a sentimental and mystical attitude to nature. But that is not the view of some hard-headed practical lawyers. In 1972 an article by a professor of law in California, Christopher Stone, examined the singular thesis: Should Trees have Standing? The article has since been published as a book, together with judgement from the Supreme Court on the legal case which prompted Stone's article‡.

The circumstances which brought the action to the Supreme Court were these. The United States Forest Service had granted a permit to Walt Disney Enterprises Inc to "develop" Mineral King Valley in the Sierra Nevada mountains. The decision was challenged by the Sierra Club, which acts vigorously to defend natural objects in America. The Sierra Club lost its case for a reason which would apply to an analogous case if it were to be brought to the courts in Britain, namely because the Club had no sufficient "personal stake in the outcome of the controversy." But three members of the Supreme Court dissented from this decision, and one of the dissenting judgements, by Mr Justice Douglas, drew its inspiration from Stone's article in the California Law Review. He said: "The critical question of 'standing' would be simplified . . . if we fashioned a federal rule that allowed environmental issues to be litigated before federal agencies or federal courts in the name of the inanimate object about to be despoiled . . . Contemporary public concern for protecting nature's ecological equilibrium should lead to the conferral of standing upon environmental objects to sue for their own preservation."

In his lively essay, Stone examines the way rights in law have been conferred upon children (who have not always had rights in law), women, subject peoples formerly enslaved, and so on. He then reminds us that the "world of the lawyer is peopled with inanimate right-holders: trusts, corporations, joint ventures, municipalities . . ." So there is nothing unreasonable about putting natural objects, as the law puts other non-human things, into the category where their interests can be defended in courts by properly recognised guardians. Of course, before the principle could be adopted, many subsidiary questions (such as: Who should be the guardians?) would have to be settled. But the idea is worth serious reflection for it would be one more step in the evolution of an environmental ethic which does not rest on the assumption that nature is made for man. ☐

---

‡Stone, C. D., *Should Trees have Standing?* (Kaufmann, Los Altos, California, 1974).

The attack on tropical disease

Alex Dorozynski looks at the World Health Organisation's efforts to relieve man of one of his major burdens

IN spite of recent expressions of concern about the new economic order, interdependence of nations, and cooperation, there is one area of enormous importance to the developing world that has largely been ignored that of tropical diseases. They affect several hundred million people, represent a permanent human burden, and a major obstacle to development. Tropical disease research has hardly benefited from the explosion of knowledge in bio-medical sciences that has taken place in the developed world.

In fact, some of the tropical diseases are now recrudescent, because parasites have become resistant to drugs and vectors to insecticides, because agricultural development sometimes contributes to the creation of conditions required for a disease to become endemic, and because international aid toward the control of tropical diseases has shrunk in the face of increasing costs. In the past year, the World Health Organisation (WHO) has been mounting a new attack on these diseases. The approach is novel, and the outlook promising, although one major element of uncertainty still remains: will there be enough money to carry out this long term programme?

The global annual investment in tropical disease research is estimated by the WHO at about $30 million, which is a mere pittance of money in comparison to huge budgets devoted to other areas of bio-medical research. Advances in treatment and control of tropical diseases have been painstakingly slow, in spite of the fact that most of the causative agents are relatively simple parasites belonging to the lowest orders, protozoa or worms, that in most cases are completely incapable of independent life and rely for survival on the highly specialised environment provided by two or three or sometimes more successive hosts.

"According to the law that viability is inversely proportional to the stringency of ecological requirements," says Professor Christian de Duve, "the pathogenic parasites certainly occupy the bottom of the scale. They are puny enemies indeed." He is the director of the International Institute of Cellular and Molecular Pathology, Brussels, and a member of Rockefeller University, New York. A consultant of the WHO in the new "Programme of Research and Training in Tropical Diseases", he is one of the scientists who has suggested a new approach to tropical diseases research in which the basic biology of the parasite becomes the prime target.

The diseases

Six diseases have been selected as the initial targets of the WHO's Special Programme: malaria, schistosomiasis, trypanosomiasis, filariasis, leprosy, and leishmaniasis.

- Malaria is one of the most widespread diseases in the world, affecting some 200 million people. In Africa, about one-fourth of all adults suffer from malarial fever at one time or another, and at least one million children die of the diseases every year. In several areas of Asia and South America, *Plasmodium falciparum* (one of the four human malaria parasites, responsible for the severest forms of the diseases), has developed resistance to 4-aminoquinolines, major antimalarial drugs. In Asia resistant strains have progressed westward to reach the Indo-Pakistani subcontinent, and they represent a great threat to Africa, where *P. falciparum* is the main malaria parasite.

In addition, mosquitoes have developed resistance to some insecticides and, as a result of increased costs and reduced international assistance programmes, many countries cannot afford to carry out intensive anti-malarial campaigns.

India is an example. The number of cases there of malaria had been reduced to a low of 60,000 in 1962, but last year it exceeded four million (a 70-fold increase). In Africa, there appears to be no hope of malaria control in the near future. Dr Adetokunbo O. Lucas, former president of the Nigerian Medical Research Council, who in April become the director of the WHO Special Programme, points out that several intensive pilot projects have shown that infection is so deeply entrenched in the environment that spraying of insecticides and drug distribution are not sufficient to interrupt transmission.

In some parts of the world, malaria has inadvertently been promoted by irrigation. A typical example is that of the Gezira, the region between the White Nile and the Blue Nile south of Khartoum. Irrigation had turned the Gezira into the most densely populated and most prosperous agricultural region of Sudan, and the periodical drying out of peripheral irrigation ditches, possible when the area was almost exclusively planted to cotton, had to be abandoned when other crops (notably, rice) were introduced. In 1950, an outbreak of malaria affected more than half of the total labour force, and since then malaria has been endemic. A major effort is now under way to keep the diseases under control.

- Schistosomiasis, caused by trematodes (or fluke worms) also affects about 200 million people. Free-swimming larvae (or cercariae) penetrate through the skin of a person entering the water, migrate to the liver where they mature into adult worms that settle inside blood vessels and go on laying eggs for several years. Infected people may become emaciated, with an enlarged spleen and bloated abdomen, and many develop cancer. It is possible to treat individual cases with injections of antimonials and other compounds, but most of these can cause severe side effects. There is no adequate method for mass treatment.

Schistosomiasis is often associated with rural development. Thus the incidence of the disease has been increasing in Egypt and Sudan since the creation of Lake Nasser, and in Ghana since the construction of the Akosombo Dam on Lake Volta. In Northern Nigeria there has been a three-fold increase in three years around the lake created by the Kainji dam, and even in the semi-arid Arabian Peninsula irrigation has introduced schistosomiasis to regions where it did not previously exist.

- Filariasis affects about 300 million people. The two major filarial parasites, *Wucheria bancrofti* and *Brugia malayi*, transmitted by mosquitos, infect about 250 million people (mainly in Africa, the Indian subcontinent, South-East Asia, the Philippines, China, and the Pacific Islands). They cause elephantiasis of the legs, arms and genitals, by obstructing the flow of lymph.

One form of filariasis is onchocerciasis (or river blindness), caused by *Onchocerca volvulus*, transmitted by *Simulium damnosum*—the blackfly. In the upper basin of the Volta river, more than a million people are infected and thousands are blind. A costly control programme has been initiated in seven of the most affected countries; it involves the spraying from helicopters of the often inaccessible fast-flowing streams where the blackflies hatch, and the treatment of infected persons, but there is a need for better drugs, with less side effects and more effective against adult worms.

- Trypanosomiasis affects some 10 million people. The African form of the disease, sleeping sickness, is endemic over about 10 million square kilometres of land, much of it fertile but abandoned to the tsetse fly, vector of the disease. (It is estimated that this land could provide for a cattle population of 125 million.) The South American form of trypanosomiasis is Chagas' disease, incurable and fatal (it destroys the heart).
- Leprosy, one of the most perplexing infectious diseases, also affects at least 10 million people. Although Hansen's bacillus, or *Mycobacterium leprae*, was described more than a hundred years ago, it has not been grown *in vitro* (or, at least, no reported culture has yet been confirmed). Even the mode of transmission of the disease is not well understood, and although it is generally believed that infection is from man to man, Hansen's bacillus has also been identified in insects, and some researchers believe their bite may also be involved.
- Leishmaniasis, the sixth disease included as a target in the initial stages of the Special Programme, is caused by various protozoa of the genus *Leishmania*. Two of its forms are lethal: the South American *espundia*, which kills by destroying the face, and visceral leishmaniasis, or kala azar.

The programme

There are several reasons why the timing for a renewed effort to develop remedies against these diseases is propitious.

The means to control and treat them are limited, and there is relatively little research directed towards new remedies. A number of recent findings, however, both in parasitology and fundamental biology, can be used to explore new approaches. Several such approaches have been identified, and "task forces", or scientific working groups, have been formed by the WHO, consisting of top scientists in various disciplines, to pursue specific goals.

One group, for instance, is concerned with immunology of malaria, and its ultimate goal is to develop reliable, long-acting vaccines, which would undoubtedly revolutionise the control of malaria. Infection has long been known to produce a certain degree of immunity, and some experimental vaccines have already been produced Last year, it was shown that some people possess a genetic factor that prevents the invasion of red blood cells by malaria parasites. This genetic trait conferring resistance to malaria is called "Duffy negative", because red cells lack the Duffy antigen, named after the first person in whom it was discovered It appears that this antigen leads the parasites into the red blood cells, and that in Duffy negative people the absence of the antigen protects the blood cells against the parasites Some preliminary experiments indicate that certain enzymes can block the antigen, thus conferring anti-malarial protection to the cells.

An even more important finding was announced only last April by Professor William Trager of the Rockefeller University in New York, who is a member of the Special Programme's "task force" on immunity to malaria he has succeeded in maintaining a laboratory culture of *Plasmodium falciparum* for three months This is the first time that a continuous culture of any of the malaria parasites has been successfully established *in vitro* and gone through a large number of multiplication cycles Large amounts of pure *P falciparum* can now be available, and this is a significant step towards the development of a vaccine.

The harvest of a large number of *Mycobacteria leprae* is also possible since researchers in Louisiana found in 1971 that injection into nine-banded armadillos caused massive infection of the animals. (Previously, infection had been achieved only in mouse footpads, and it was very limited.)

The WHO's scientific working group on immunology of leprosy has already engaged in antigen preparation and purification, and three promising antigens have been isolated, one in Venezuela, one in the United Kingdom, and one in the USA. As with other task forces, the specialists from several countries meet periodically, either at the WHO headquarters in Geneva or elsewhere, to coordinate their efforts. There is good hope that a practical vaccine, providing long-term protection against *M. leprae* can be developed, and a tentative schedule has already been established if all goes well, field trials should start in four or five years

Less is known of the immunological aspects of schistosomiasis, filariasis, trypanosomiasis and leishmaniasis, but there is, nevertheless, hope that vaccines can also be developed against at least some of these diseases

Recent research has shown, for instance, that the *Schistosoma* parasite has a very sophisticated system to ensure its survival in spite of the immunological defences of the organism it invades When a free-swimming preadult cercaria penetrates through the skin of a person, it does trigger antibody production But within a few days, by the time the parasite reaches maturity. It appears to cover its antigens with proteins that mimic the host's own antigens Thus, if immunisation could increase the organism's reaction against the pre-adult cercaria, the schistosoma could be destroyed before it had time to protect itself.

High technology

At the same time, other participants in the Special Programme are exploring the possibility of entirely new approaches, relying on recent bio-medical knowledge Professor de Duve, for instance, is attempting to apply "lysosome therapy" to some of the tropical diseases "Lysosomes," he says,

> are essentially miniature little stomachs, which occur in all cells One of their principal functions is to serve in the digestion of food 'eaten' by the cells by a special capture process, called phagocytosis or pinocytosis, depending on the size of the food particles taken in As with humans, cells may be greedy or frugal, and they may exhibit a wide variety of tastes Our purpose is to take advantage of these differences to kill certain cells selectively by poisoning their favourite food .To do this, we bind the poison to a carrier molecule in such a way that it will be released when it gets in the lysosome, that is, in the stomach of the cells that have eaten this poisoned food.

Experiments in mice carried out at the International Institute of Cellular and Molecular Pathology in Brussels have shown that such "selective poisoning" can be effective against at least one *Trypanosoma* parasite A similar approach can be tried for the treatment of diseases such as schistosomiasis or onchocerciasis, caused by worms with very tough skins, whose weak points may be their "stomachs". Even the leprosy bacillus, which has no lysosomes of its own, may be susceptible to similar "poisoning" because it develops within membrane-bound vacuoles resembling lysosomes in the macrophages of its host.

Enzyme therapy is another possible approach. It is known, for instance, that fertilised eggs of the nematode worm, another parasite of man, manufacture chitin, a substance that protects the cell, since mammals do not produce chitin, interference with the enzymes needed to produce it could destroy nematode eggs without affecting the human host.

Interference with the parasites' nervous system could also be explored —notably by acting on chemotaxis, an important determinant of behaviour, or on neurotransmitters (experiments with *Caenorhabditis elegans,* a free-living soil nematode, have shown that tetramysole, an agonist of acetylcholine, a major neurotransmitter, effectively paralyses the worms, arresting feeding and mobility).

Vector control, likewise, can benefit from goal-oriented research, notably in the area of biological vector control. It is known that parasites can be infected by other parasites (for instance, mermithid worms can infect and kill the tsetse fly). But basic research into the biology of the insect and its predator, and into the ecological impact of such an approach, must first be carried out.

These are "high technology" approaches, that require the commitment of skilled manpower and adequate budgets. Their goal is the development of remedies on the basis of knowledge of parasite function and biology, rather than through often empirical, large-scale screening, such as has been widely used until now in anti-parasitic drug research.

The purpose of the Special Programme of Research and Training in Tropical Diseases is not, however, limited to such research, much of which must be carried out in institutes, universities, and pharmaceutical laboratories in the developed world. The very countries most affected by tropical diseases will be associated with the programme

At the beginning, the focus will be on Africa, which has the highest prevalence of the six diseases and where multiple infection is almost the rule. Several African countries have expressed their willingness to participate in and contribute to the programme, and Zambia has offered laboratories in the large Ndola hospital complex for the creation of a multidisciplinary research centre bringing under the same roof different aspects of laboratory research and clinical medicine. Strengthening of existing laboratories, creation of new ones if necessary, and training of additional indigenous personnel, are planned as part of the programme to promote self-reliance in the very parts of the world where tropical diseases are prevalent.

Several meetings devoted to the Special Programme, co-sponsored by the WHO and the United Nations Development Programme, have already been held, and scientific work has started with the help of initial funds contributed last year by several nations and organisations But a long-term commitment is needed, as the programme cannot be financed from the shrinking budgets of the WHO or UNDP This is why a meeting with potential donor nations and agencies will be held later this year. In view of the magnitude of the problem being tackled, and the results that can be expected, the initial annual budget of $15–$20 million (the price of a jet fighter or a few miles of superhighway) seems reasonable enough. ☐

Assessing the OTA

Congress's three-year-old Office Technology Assessment (OTA) has come under sharp, and potentially damaging, criticism from another Congressional committee and from the former chairman of its own advisory council. Both have argued that it has failed to live up to expectations and that there is still no clear understanding of its role and function. Colin Norman reports from Washington.

ESTABLISHED in 1972 by an Act of Congress, OTA is meant to furnish Congress with advice and analysis concerning scientific and technological issues. Its mission is frequently described as providing an early warning system on such matters. But its chief problem, which lies at the root of much of the criticism, is that on the one hand it is expected to study long-term issues, while on the other it is supposed to help Congress, which is more concerned with yearly budgets and two-yearly elections.

OTA studies and reports on matters referred to it by other committees of Congress, and it also generates some studies itself. Its operations are managed by a Director, Emilio Q. Daddario, a former Congressman who wrote the original legislation which led to OTA's establishment, and its policy is provided by a board consisting of six Senators and six Congressmen. In addition, an advisory council, whose members are drawn from industry and academia, provides advice on OTA's operations.

The first criticism of OTA's operations surfaced in the office's recently-published annual report, which contained a letter from Harold Brown, President of Caltech, resigning as chairman of OTA's advisory council, and a response from Representative Olin Teague, chairman of the office's governing board.

Written last December, the letter begins with some words of praise for a few OTA studies, but criticises the fact that the office has taken on too many trivial tasks and asserts that "few of us on the council, I believe, would say that we are satisfied with what has been accomplished, compared with what we hoped for and still believe possible". Brown suggests in particular that OTA has been concentrating too much on immediate problems. "inevitably there are strong pressures on the Congress as well as on the Executive Branch to concentrate on immediate problems. Certainly those problems must be faced as they arise. But there needs to be a balancing effort within the Congress to foresee problems of the medium and even the long term future".

Less gentle criticism has come from an obscure Congressional body, known as the House Commission on Information and Facilities, chaired by Representative Jack Brooks of Texas. On the basis of an 8-month study, the commission last week issued a report which concludes that "OTA remains substantially short of reaching levels of performance reasonably expected of an information resource of its size and cost and access to expertise". The report, in short, suggested that OTA has been beset by operational problems and by lack of a clear definition of its functions.

The report states that the Commission found confusion among OTA's staff, council and board, and between OTA and some Congressional committees, over the office's role and responsibilities. It suggests, therefore, that OTA's statutory authority should be reviewed, and a clear definition of technology assessment should be drawn up, presumably so that OTA's territory is staked out and so that there's no overlap of its functions with those of the Congressional Research Service or the General Accounting Office. The report goes on to state, however, that so far there has been no such overlap.

More specifically, the report expresses reservations about the fact that OTA has been performing a growing share of its studies itself, rather than having them done by outside contractors, and suggests that OTA should have a firmer policy on which kinds of studies should be performed in-house. That criticism conflicts, however, with a comment made by Brown in his letter. Listing some "substantial advances" made by OTA, Brown notes that "an initial tendency to think almost solely in terms of contracted studies has been succeeded by a more balanced procedure involving advisory panels, contracted studies, and some (as yet rather little) in-house assessment work".

But perhaps the Commission's most biting criticism concerns OTA's administrative structure. "Organisationally", it says, "OTA lacks the minimum of orderly structure", and it suggests that OTA should begin immediately, if necessary with the help of management consultants, to put itself in order.

Finally, both the Commission and Brown criticise the poor relations which have developed between OTA and its advisory council. "At one time or another", Brown states, "most Council members have expressed frustration about the relatively large amount of time, effort and persistence that they have invested in terms of the effect they feel they have had I believe that the important task of strengthening communications between the

NSF budget goes to conference

HOPES for at least a modest increase in funds for basic research in the United States have been unexpectedly revived by the Senate. After intensive lobbying from scientific and higher education organisations, the Senate last week restored most of the money which the House of Representatives had slashed from the budget of the National Science Foundation (NSF), and the matter must now be decided in a conference committee consisting of members from each body. It's a fair bet that NSF will end up with a small increase, though not as great as the 20% boost proposed by the Ford Administration.

President Ford's budget request for NSF for the fiscal year which begins on October 1 was designed to offset the effects of inflation, which has eaten deeply into support for basic research over the past few years But the House slashed nearly $60 million from NSF's budget, giving the agency less than a cost-of-living increase, largely on the grounds that basic research isn't too badly off in relation to other items in the federal budget.

The House's parsimony prompted a massive letter-writing campaign to key Senators, and a move to restore the funds, led by Senators Charles Mathias of Maryland and Edward Brooke of Massachusetts, proved successful. The senate agreed to Mr Ford's proposed 20% increase, in spite of opposition from Senator William Proxmire, Chairman of the Senate subcommittee which handles NSF's budget request. Proxmire said that he believes the increase is much too generous, but was outvoted in the committee.

The conference committee will probably settle on a figure about half way between the levels approved by the House and Senate, which would at least give basic research its first real increase in about five years.

Board and the Council needs to be faced during the coming year". And the House Commission on Information and Facilities, noting that there has been considerable confusion over the role of the council, suggests that "substantial revision of the Council's statutory function, or its abolition, be proposed on grounds that unless Council contributions are integrated more effectively in the policymaking process, its existence can only be a source of frustration and disharmony within the agency".

There is clearly going to be more debate before OTA is able to establish a comfortable role in which it acts as a long-term analyst and at the same time provides advice geared to Congress's short-term outlook. □

EEC

European science policy sought

The European Commission recently unveiled proposals for a Community science policy. Progress towards the aim of a common approach, reports Chris Sherwell, may prove to be more pedestrian than the enthusiasts are prepared to admit.

IF the expressions of satisfaction emanating from the vicinity of the Berlaymont Building in Brussels are anything to go by, Europe is now well on its way towards forging a science and technology policy for itself. The Commission of the EEC, which has its headquarters there, recently unveiled the results of a closed symposium which took place under its auspices in Milan towards the end of May.

The aim of the symposium was to gather suitable suggestions for guidelines regarding research and development which the Commission might present to the relevant Council of Ministers later this year. This it reckons to have achieved. Among the 100-odd participants were members of the European and the various national parliaments; members of the Commission and of the Economic and Social Committee (a consultative body serving the EEC and Euratom), and government officials; and the customary host of scientists, engineers, industrialists and trade unionists who help to make meetings like this more models of organisation than of representativeness.

The three-day symposium, at Milan's International Institute for Management of Technology, was organised by Directorate General XII (Research, Science and Education) of the Commission with the aid of CERD (the European Research and Development Committee), which is an independent 21-member body of scientists and engineers established by the Community in 1973 to advise the Commission on the formulation of a common science policy. It took place in the context of an effort finally launched two years ago to sow the first seeds of a revamped Community science and technology policy to replace the old sectoral approach of the previous sixteen years.

That effort in fact had its real beginnings many years ago, but it was only in January 1974 that the Council of Ministers found itself able to give expression to sentiments voiced at the Paris Heads of Government meeting in October 1972; the Council passed four resolutions which would provide a basis for a broad Community science and technology policy. The resolutions covered matters like coordination, participation in the European Science Foundation and programmes of action. The Commission was landed with the task of looking at the science policies of the nine member states with a view to producing Community-wide projects and a common approach externally.

The hope was that the terms of a full-blooded European science policy could be finalised by the end of 1976. The Council, when it met again in June 1975, urged that discussions on the objectives of such a policy be held "without delay", and the Milan symposium, being the major part of those discussions, heralded the end of this first phase in the new Community approach. The next phase begins if and when the Council approves the recommendations of the symposium's five working parties, each of which aimed to tackle separate areas of interest.

Recommendations

The Commission document sumarising the working parties' recommendations, taken as a whole, does not make exciting reading, being littered throughout with empty phrases characteristic of all ostensibly agonising searches for lowest-common-denominator agreements. Hidden in the interstices of the Commission's denatured language, however, is some sort of basis for the optimism now being expressed so expansively by the Director General at DGXII, Herr Gunter Schuster. Here, in essence, is the gist of the recommendations.

Working Party I: Long term objectives and priorities. The group recommends that a suitable instrument "such as proposed in 'Europe+30' " be established "at the earliest possible time", and that in the meantime a "small unit of specialists" be set up in or be linked to DGXII "without delay". Lord Kennet from Britain dissented on the latter point, arguing that such a staff should be actually in DGXII to avoid the danger of it becoming a substitute for Europe+30.

Among the many areas of high priority for research in the long term, the working party includes Europe's ecological system, climatic changes, water management and food shortages.

Working Party II: Medium term objectives and priorities. The main theme informing this group's recommendations emphasises the need to do more to bring innovations to potential customers. The group wants to "make operational, within the Communities (the EEC, the European Coal and Steel Community and Euratom), structures for securing and examining research and development proposals coming from any public or private European organisation". It also wants "to relaunch the Community development contract procedure" reserved for *European* [group's italics] groups of enterprises and multinationals, and "to establish structures for conveying the Commission's intentions". A consultative comittee for industry is suggested.

More specifically, the group hopes that certain subjects now neglected or insufficiently developed will receive "special consideration"—among them, hydrographical problems arising out of the existence of multinational basins, European epidemiological research, recycling and reclamation, basic biological research, and ethical problems in genetic matters.

Interestingly, there is a frank acknowledgment of the constraints within which such a policy can work. The human and financial resources the EEC has at its disposal, the group says, "are not considerable", and are so concentrated as to prevent the needs of a real European policy being met over a wider field—and in certain fields, the group declares, the EEC could not be satisfied with the role of a mere catalyst. The scientific and technical activity of the EEC, it stresses, is "an essential part of a true European economic community", and it expresses its hope for a separate budget that would allow further progress.

Working Party III: Coordination of national policies. After recognising that a common policy can only be built up "slowly and step by step out of the coordination of national policies and common sections", this group deals with coordination in four fields.

In basic science, it says, "the self-coordination of scientific groups, institutes, organisations and associations is the most important and useful instrument of coordination"—and here the group has in mind the cooperation already operating between Britain's SRC, France's CNRS, Germany's Max Planck Institutes, and so on. Where research is carried out almost totally by industry, coordination should be limited to the "harmonisation and coherent development of support activities in the member states".

Research and development for "public services and tasks", on the other hand, "is undoubtedly the central object for coordination in the Community", because in these spheres the national government have sufficient responsibilities. Finally, in the mixed sector ("the most difficult sector for coordination"), where it is noted that funds in all countries are heavily concentrated in a few areas (nuclear, space, electronics), the group states rather vacuously that projects performed by industry but financed by government "should not be excluded from coordination".

Working Party IV: Innovation policy. Industrial enterprise, says this group, is "the main actor in the innovation process", but it is governments which have to create a favourable climate—and promotion of innovation at the Community level "is at present hampered by the lack of a common industrial policy", which it calls "a serious obstacle to the development of comprehensive industrial R & D programmes".

The Community, it says, can make "an important contribution" towards creating the right climate: among other things, it could support cooperation in long term industrial research and development (fusion, aerospace, solar energy), finance demonstration projects, make more accessible those public markets where state agencies are large buyers of technology, and improve access for small and medium sized industries to technological innovation. The group, like the second working party, recommends that the Commission set up an industry consultative committee to give industrial viewpoints on the Community's R&D policy.

Herr Schuster, Director General at DGXII.

Far from judging the present economic plight of European countries a deterrent to innovation, the group rather believed this problem called for a special effort. Similarly, state participation in the field was less a constraint than a stimulus, although state encouragement of specific projects—not so much in fields of obvious community interest (energy supply, public transport) as in fields like cybernetics—demanded fundamental discussion. The general feeling was that there was insufficient coincidence between the long term projects of member states and those of the Community—and that the liaison now lacking could, unsurprisingly, only be promoted through greater coordination. Plainly, though, the overlap with Europe's much-sought-after industrial policy is regarded as vital to the success of any research policy relating to industry.

Working Party V: Dissemination and exploitation of results. The group recommended that "a readily and selectively accessible dissemination system for information about R&D" be set up within the Community, based on national information services and existing contacts between organisations. It further recommended that the Community's four-establishment Joint Research Centre (JRC) should have greater involvement in the exploitation of its own inventions, and that the Community should be able to provide companies with incentives where necessary (through exclusivity or lead times, for example). A small team of experts should also be available, with close links to scientists in the JRC and contractors, on the one hand, and to exploitation organisations in member states on the other.

Long way to go

All of which suggests that there is a long way to go before a real European policy is actually in operation. Although the recommendations reveal a rather limited number of specific institutional proposals, the general disposition in favour of a European approach, and one buttressed through additional budgetary support at that, shines through. The main emphasis, naturally enough, is on the key-word "coordination", perhaps the most crucial block in the fragile Community science edifice. But the question of how best this might be achieved, although begged throughout, does not receive a great deal in the way of answers.

Not that Europe's welter of institutions does not already include a goodly proportion of science-oriented bodies equipped to supply the answers. Apart from CERD, the most important is probably CREST, the Scientific and Technical Research Committee. It is the product of the January 1974 Council resolution on coordination, and is blessed with the task of "helping Community institutions to define objectives and securing the development of a common policy for science and technology." According to Working Party III, it is CREST which is to be regarded as the central committee where "coordination in all fields of R&D is focused", and Community officials looking to CREST to translate proposals into reality do point to its achievements—in the implementation of Community projects on new energy sources and scientific information, for example, and in planning cooperation with non-Community countries, which it does within the context of COST, the Committee of Senior Officials in Scientific and Technical Research.

But there is little question about how much has really been achieved so far. No one at the Commission doubts that progress has been and will continue to be slow, or that CREST has yet to come into its own. There are pilot projects in hand, in the fields of energy, medical research and the determination of research and development indicators, and these represent practical attempts at coordination and alignment. For the moment, however, they merely supplement existing instruments of coordination, which also include the Advisory Committees on Programme Management (ACPMs).

The perspective being adopted in Europe is thus distinctly medium to long term—CERD itself has proposed that a European Science Year be organised in 1978 or 1979, just before the United Nations World Science Year in 1980. In places the Commission's document makes a tilt towards the themes of humanising science and of Third World development, and there does seem to be an underlying view which argues that, if a European science policy is to have any chance of success at all, then somehow science itself will have to be brought closer to the proverbial man in the street, and be made to be seen as relevant to his needs. But if that laudable view is scuttled by the trials of actually identifying Europe's research requirements, and of formulating an acceptable policy (particularly regarding the distribution of its benefits and its burdens), there should be few surprised faces. □

news and views

Factor VIII

from D. E. G. Austen

FACTOR VIII activity is essential for normal blood clotting and haemostasis, and an inherited deficiency of this activity occurs in haemophiliacs and patients with von Willebrand's disease. In von Willebrand's disease there is also a deficiency of a closely related substance called factor VIII-related antigen (Zimmerman *et al.*, *J. clin. Invest.*, **50**, 244; 1972). The presence of this antigen is demonstrated by raising heterologous antibodies in animals to factor VIII preparations and using them in immunoelectrophoretic procedures. Precipitin lines reveal the presence of factor VIII-related antigen in the plasma or serum of both normal people and haemophiliacs, but not in the plasma or serum of patients with severe von Willebrand's disease.

Haemophilia is determined by an X-linked recessive mechanism of inheritance while von Willebrand's disease is inherited as an autosomal dominant condition. As far as is known, there is no inherited deficiency of antigen alone and the concentration of antigen in normal people and most patients with von Willebrand's disease is roughly proportional to their factor VIII activity. These various relationships between factor VIII and the antigen suggest that their production *in vivo* proceeds by a common route at some stage.

Subunits

Factor VIII is a glycoprotein and many workers have reported it to have a molecular weight of more than 10^6 as determined by gel filtration chromatography. It is relatively easy to bring about an apparent reduction in this molecular size using high or low ionic strength (Weiss *et al.*, *Thromb. Diath. haemorrh.*, **27**, 212; 1972; Owen and Wagner, *ibid*, **27**, 502; 1972) or reducing agents (Austen, *Br. J. Haemat.*, **27**, 89; 1974) and the factor VIII activity then appears by gel filtration to have a molecular weight of around 230,000. It has been suggested recently, however, that experimental conditions affect the speed at which low molecular weight factor VIII passes through the gel filtration column (Switzer and McKee, *J. clin. Invest.*, **57**, 925; 1976) and so the exact values of molecular weight should not be emphasised at this stage. Factor VIII-related antigen remains unchanged by variations in ionic strength or by very mild reducing conditions. As a result, gel filtration of the products of such reactions separates factor VIII activity from the antigen, although the extent of this separation is still a matter of discussion. Two different hypotheses have been suggested to explain these results. The first is that factor VIII is made up of several subunits which can be disaggregated, while at the same time, factor VIII-related antigen circulates as a completely separate molecule. The second possibility is that factor VIII consists of a small active molecule which is bound as a passenger to a large carrier molecule of factor VIII-related antigen and that disaggregation experiments simply separate the two.

Several workers have now also cleaved factor VIII-related antigen into subunits. Some have effected this in moderate reducing conditions and retained the antigenicity of the protein (Austen *et al.*, *Nature*, **253**, 55; 1975; Peake and Bloom, *Thromb. Haemostasis*, **35**, 191; 1976). Others have used severe conditions along with sodium dodecylsulphate (SDS) gel electrophoresis and report that they can detect the protein using staining techniques (Marchesi *et al.*, *J. clin. Invest.*, **51**, 2151; 1972; Legaz *et al.*, *J. biol. Chem.*, **248**, 3946; 1973; Switzer and McKee, *J. clin. Invest.*, **57**, 925; 1976). In both cases the molecular weight value obtained is close to that of the small active factor VIII fragment and this may suggest that the antigen and factor VIII are two proteins with a similar basic structure.

Antibodies

Another field of useful investigation has been concerned with the development of factor VIII antibodies. In patients suffering from haemophilia, antibodies can develop to infused therapeutic concentrates of the factor. Such antibodies will inactivate factor VIII both in its high molecular weight or its low molecular weight form. They are non-precipitating and are not believed to cross react with factor VIII-related antigen. But with severely affected von Willebrand's patients who have a minimal level of antigen the precipitating-type of antibody can develop, as Manucci *et al.* show (page 141 of this issue of *Nature*). These are directed against factor VIII-related antigen and have only a low level of cross reaction towards factor VIII activity.

More information can be obtained by studying antibodies produced in rabbits after infusion of factor VIII and the antigen. Here there is general agreement that antibodies can be separated which are directed against factor VIII-related antigen. On the other hand, antibodies which are directed against factor VIII-related antigen have been reported to have varying degrees of cross reaction with factor VIII activity, possibly depending on the experimental conditions. This work has been extended recently by a paper (Ratnoff *et al.*, *Blood*, **47**, 657; 1976) which reports that antibody directed against factor VIII-related antigen does not inactivate the low molecular weight fragment of factor VIII even though it does react with native factor VIII.

Interpretations

A reasonable solution to some of the apparent differences in reported results is suggested in a paper (Kernoff, *Nature new Biol.*, **244**, 148; 1973) which shows that the antibody against factor VIII-related antigen will precipitate factor VIII but that the complex retains factor VIII activity. As a result, an apparent inactivation could be obtained if the supernatant solution was assayed after centrifugation. An interesting confirmation of this was also seen in immunoelectrophoresis experiments (Bird and Rizza, *Br. J. Haemat.*, **31**, 5; 1975) where the actual precipitin lines formed by factor VIII-related antigen and its antibody were shown to possess factor VIII activity. (The sample subjected to the immunoelectrophoresis contained both active factor VIII and antigen.) Clearly factor VIII and factor VIII-related antigen have determinants in common, or alternatively the two are bound together.

The bonding of active factor VIII subunits must rely on electrostatic attraction since ionic strength changes are sufficient to sever them. Chemical reduction has also been shown to disaggregate factor VIII and this might be due to cleavage of intramolecular disulphide bridges between different parts of the same factor VIII subunit. When these are severed, different sections of the subunit could alter spatial configurations, and in that way geometrical changes would occur to a point where the electrostatic forces could no longer keep the subunits together. Bonds between the subunits of factor VIII-related antigen must be considerably stronger because more vigorous chemical reduction is required to disaggregate them. It would be anticipated that disulphide bonds are involved in some way but further conclusions are not possible at this stage.

Although there is considerable disagreement about the interpretation of the reported data on factor VIII, some useful conclusions can be drawn. Factor VIII-related antigen is shown to be a large molecule with a molecular weight of more than 10^6. Active factor VIII can be separated from factor VIII-related antigen and to that extent they must be considered as separate entities. But they have intriguing similarities. They are difficult to separate unless factor VIII is cleaved into subunits and they have some antigenic determinants in common. The size of their subunits seems to be similar. Exercise and fear in the human subject bring about a proportionate increase in both. It is also important that the infusion of haemophilic plasma into a patient with von Willebrand's disease produces factor VIII activity.

These results are fascinating and most of them could possibly be explained on the basis of several hypothesis. In my opinion, however, the most reasonable hypothesis is that factor VIII and factor VIII-related antigen are separate molecular species with a basic structural similarity. This does not exclude the possibility that other species with that same basic structure are also present. It is interesting to speculate that such a substance, or even factor VIII-related antigen itself, could be the precursor of factor VIII. If this were the case, then treatment of haemophilia in the future might be based on converting a precursor into its active form rather than direct factor VIII replacement. □

Peptides in brain and intestine

from A. G. E. Pearse

In 1931, while studying the distribution of acetylcholine, von Euler and Gaddum (*J. Physiol.*, **72,** 74) detected, in alcoholic extracts of equine brain and intestine, a smooth muscle stimulating and hypotensive agent which was later (Chang and Gaddum, *J. Physiol.*, **79,** 255; 1933) called substance P (for powder). Its identity as a peptide (protein) was soon established (von Euler, *Skand. Arch. Physiol.*, **73,** 142; 1936) but its isolation and characterisation had to wait for almost 40 years (Chang and Leeman, *J. biol. Chem.*, 245, 4784; 1970; Chang, Leeman and Niall, *Nature*, **232,** 86; 1971).

The story of substance P can now be seen to provide nearly all the clues required for an understanding of the recent spate of reports of peptides common to brain and intestine. The latter region can more accurately be described as 'gastrointestinal tract and pancreas' and the peptides are regarded on the one hand as presumptive or proven neurotransmitters and, on the other, as presumptive or actual hormones.

A current list of the common peptides, with their original and new locations, is given in Table 1. The first two peptides in the list are primarily of neural origin. Demonstrated in brain by radioimmunoassay, with highest concentrations in the substantia nigra and hypothalamus, substance P has now been localised, by immunocytochemical techniques, not only in the central nervous system (Hökfelt *et al.*, *Science*, **190,** 889; 1975), but also in some of the enterochromaffin (EC) cells of the gastrointestinal tract (Pearse and Polak, *Histochemistry*, **41,** 373; 1975) and bile ducts. This peptide (H–Arg–Pro–Lys–Pro–Gln–Gln–Phe–Phe–Gly–Leu–Met–NH_2) is probably widely distributed in primary sensory neurones and their processes, and in nerve terminals in many areas of the brain.

Somatostatin, named for its growth hormone release inhibiting properties, was isolated from ovine hypothalamus and characterised as a tetradecapeptide (H–Ala–Gly–Cys–Lys–Asn–Phe–Phe–Trp–Lys–Thr–Phe–Thr–Ser–Cys–OH) by Brazeau *et al.* (*Science*, **179,** 77; 1973). Later found to inhibit release of a much larger number of endocrine peptides, including insulin, glucagon and gastrin, somatostatin was detected by radioimmunoassay in the stomach and pancreas, in concentrations equal to those recorded in the hypothalamus (Arimura *et al.*, *Science*, **189,** 1007; 1975). It has been localised immunocytochemically in the neurones of the nucleus periventricularis of the hypothalamus, in nerve fibres in the neurohypophysis and in some nerve fibres in the wall of the intestine (Hökfelt *et al.*, *Acta endocr. Suppl.*, **80,** 200; 1975).

Using similar immunocytochemical techniques several groups, independently, have now demonstrated somatostatin-like immunoreactivity in the D cells of the pancreatic islets and upper gastrointestinal tract. Consideration of the physical associations of the D cells with cells producing insulin, glucagon and gastrin leads to the supposition that the actions of the peripheral variety of this hormone are paracrine, directed that is to neighbouring cells and tissues, rather than truly endocrine. The last two peptides in Table 1 are products of two types of gastrointestinal endocrine cell belonging to the APUD series (Pearse, *Proc. R. Soc. Lond.*, **B170,** 71; 1968; *J. Histochem. Cytochem.*, **17,** 303; 1969). The name is an acronym based on their amine-handling qualities (amine content and/or amine precursor uptake and decarboxylation), but it stands for a larger spectrum of common cytochemical and ultrastructural qualities.

Gastrins, of whatever molecular species, are almost completely restricted to the G cells of the pyloric antrum of the stomach. Contrary to recorded opinion (Greider and McGuigan, *Diabetes*, **20,** 389; 1971), there is no gastrin in the adult endocrine pancreas.

Last year a gastrin-like peptide was demonstrated by immunoassay in extracts of human and animal brain (Vanderhaegen *et al.*, *Nature*, **257,** 604; 1975), and levels in the cerebral grey matter were as high as 200 ng per g of dry tissue. Since it eluted later than gastrin-17 on gel filtration, the new peptide must be regarded as closely related to, rather than identical with, gastrin.

Vasoactive intestinal peptide (VIP) is a 28-residue peptide originally isolated from porcine duodenum and shown to be structurally and biologically related to secretin and glucagon (Mutt and Said, *Eur. J. Biochem.*, **42,** 281; 1974). Present in the gastrointestinal tract, from oesophagus to rectum (Bloom and Bryant, *Gut*, **14,** 823; 1973), it was there shown to be produced by an APUD cell now tentatively identified as the H cell (Polak *et al.*, *Gut*, **15,** 720; 1974).

Two contemporaneous papers have appeared recently both recording the presence of VIP in neural tissues. Said and Rosenberg (*Science*, **192,** 907; 1976) have measured VIP immunoreactivity in three neuroblastoma cell lines in culture, finding high levels in all three and in acid alcohol extracts of the central nervous system and sympathetic ganglia. Their values in p mol per g (wet weight) of tissue from dogs, are higher in frontal lobe cortex (19) and hypothalamus (20) than in duodenum, ileum and colon. Bryant *et al.* (*Lancet*, *i*, 991; 1976) likewise report high levels of VIP immunoreactivity in the cerebral cortex and hypothalamus of both man and pig, but in each case their average figures are lower than those recorded for the different regions of the gastrointestinal tract. In this second study a most important finding was that the bulk (94%) of VIP extractable from porcine and human brain elutes identically with, that is to say is virtually identical with, the pure intestinal peptide. Parallel immunocytochemical studies showed that in human and porcine intestine VIP is present not only in the endocrine VIP cells but also in some fine nerve fibres in the lamina propria, in the cell bodies of the myenteric plexus and in the adrenal medulla.

The two sides of the equation, neural and endocrine, are united by an essentially simple concept. First formulated some 10 years ago to explain the possession, by neurones and by endocrine cells producing polypeptide hormones, of a set of common cytochemical and ultrastructural characteristics, the APUD concept then postulated that the endocrine cells were derived from a common neuroectodermal ancestor. This was conceived as arising in the embryo from that transient but massive structure the neural crest, at one time considered as a fourth germ layer. Subsequent experimental work having shown that only seven of the 36 cells in the now amplified APUD series indeed arise from that structure, the concept has been extended to include, under the broad heading of neuroectoderm, not only the neural, tube, neural ridges and neural crest, but also the specialised ectoderm of the placodes (Pearse and Takor, *Clin. Endocr.*, Suppl. **5**, 291; 1976).

It is now postulated that all peptide-hormone-producing cells are derivatives of specialised ectoderm and therefore, effectively, of cell lines derived from the epiblast and programmed for ultimate neuroendocrine function. Thus regarded, the cells of the APUD series constitute a third division of the nervous system, functioning as third-line effectors with activities slower in onset and of longer duration than those of the second-line effectors of the autonomic division. These, in turn, are of slower onset and longer duration than those of the somatic division.

If the concept is simple and concise, its implications are diverse and far reaching. They depend, to a large extent, on the nature of the several disciplines involved and these range from neurobiology (physiology, pharmacology and biochemistry), endocrinology and peptide chemistry, through conventional and comparative embryology to, if it yet exists, the molecular variety of that science.

Table 1 Peptides common to intestine and brain

Peptide	"Original" location(s)	New location(s)
Substance P	Brain (cortex) Substantia nigra Dorsal root ganglia Peripheral nerves Substantia gelatinosa	Gastrointestinal EC cells
Somatostatin	Cerebral cortex N. periventricularis Neurohypophysis Pineal	Pancreatic islet D cells Gastrointestinal D cells
Gastrin	Gastric antrum (G cell) Duodenum	Cerebral cortex (grey matter)
VIP	Gastrointestinal tract especially duodenum, colon (H cell)	Cerebral cortex (grey matter) Hypothalamus

G, H and D, Wiesbaden classification of gastroenteropancreatic endocrine cells; EC, enterochromaffin; VIP, vasoactive intestinal peptide.

Table 2 Anuran and mammalian peptides with common amino acid sequences

Anuran peptide		Mammalian peptide	
		Nervous system	Endocrine system
Caerulein	(*Hyla* sp.) (*Xenopus laevis*)	Gastrin	Gastrin, CCK
Phyllocaerulein	(*Phyllomedusa* sp.)	Gastrin	Gastrin, CCK
Physalaemic	(*Physalaemus* sp.)	Substance P	Substance P
Uperolein	(*Uperoleia* sp.)	Substance P	Substance P
Bombesin	(*Bombina bombina*)	—	Bombesin

CCK, cholecystokinin–pancreozymin.

Neurotransmitter peptides, many probably identical with individual endocrine peptides of the gut, and others related to the peptide products of exocrine (but still APUD) cells in the cutaneous glands of anurans (Erspamer and Melchiorri, *Pure appl. Chem.*, **35**, 463; 1973), will certainly be found widely distributed in the central and peripheral nervous systems. Their precise role in these situations can be envisaged as a matter of some complexity and fuller investigations of peptidergic neurotransmission will surely make it necessary at least to augment the older cholinergic and adrenergic notation.

The list of frog skin peptides with amino acid sequences common either to neural or endocrine peptides makes interesting reading (Table 2). Anuran cutaneous glands arise from the specialised ectoderm of the region adjacent to the embryonic neural plate and neural crest. They thus have a common origin with cells producing the brain and intestinal peptides which we have been considering and presumably they have evolved, in parallel with the nervous system, as a response to the(hostile) external environment.

A similar problem is posed by the existence of peptide products which are common to the nervous system, pituitary gland, gastrointestinal tract and placenta. Notwithstanding the nomenclature by custom attached to its principal layers, the cells of the endocrine placenta can be seen to arise from the neuroectodermal epiblast of the yolk sac, a layer which is continuous with the epiblast of the neural plate (Takor and Pearse, in preparation). Thus the many peptide hormones produced by the placenta can be linked with their counterparts in other regions.

The work of Steiner *et al.* (*Rec. Prog. Horm. Res.*, **25**, 207; 1969), on proinsulin biosynthesis, provided protein chemists with a basis for several currently popular theories on the molecular evolution of peptide hormones. Steiner's own theory deriving insulin by way of a protoproinsulin from an ancestral intestinal protease, and Adelson's (*Nature*, **229**, 321; 1971) enterosecretory hypothesis deriving most peptide hormones from the entoderm of the primitive gut, seem to require reconsideration. Exact knowledge of structural correlations between brain and intestinal endocrine peptides is essential to proper understanding of their molecular evolution. Continued search for these peptides must be made in the earliest available vertebrates and in the invertebrate kingdom also.

For embryologists a clear challenge is posed by the close relationships now observed between neurotransmitter and endocrine peptides. In the hands of experimental embryologists the biological marker technique using avian chimaeras (Le Douarin, *Bull. biol. Franc. Belg.*, **103**, 435; 1969) has provided watertight evidence for the neural crest origin of a number of cells in the APUD series. Operative techniques of excision or exclusion (Andrew, *J. Embryol. exp. Morph.*, **31**, 589; 1974; Pictet *et al.*, *Science*, **191**, 191; 1976) have so far shown only that the gastrointestinal endocrine cells probably do not come from the definitive neural crest. Where they do come from is thus the problem that remains for the techniques of experimental embryology to answer.

Unquestionably the real future lies with the new science of molecular embryology.

This alone can provide an answer to the central question—how are individual cells in the embryonic epiblast programmed for neuroendocrine function and how, and at what stage, are the further series of instructions added which determine the ultimate endocrine function of each of the original cells? Already (Le Douarin, *Med. Biol.*, **52,** 281; 1974) we have learnt something of the timing and nature of the later stages of instruction but it is the problem of elucidating the earliest stages which provides the real challenge to experimental ingenuity. □

Cathodoluminescence of dislocations

from John Walker

DISLOCATIONS—misplaced planes of atoms which disturb the regular periodicity of otherwise perfect crystals—are important both theoretically and technically. They reduce a material's mechanical strength and affect its electrical properties; the quality and yield of electronic devices are inversely correlated with dislocation density. Hence dislocations have been extensively studied, and various techniques are used to observe them, including X-ray topography, electron microscopy and etch pit formation. A recent paper by Kiflawi and Lang (*Phil. Mag.*, **33,** 697–701; 1976) has demonstrated that a new weapon—cathodoluminescence—can be added to the technological armoury.

Cathodoluminescence is the release of light induced by electron bombardment, just as occurs in a television (cathode ray) tube. In earlier papers Lang and his colleagues showed that the growth history of a diamond crystal could be studied using cathodoluminescence, and reported the existence of defects, suspected of being dislocations, which emitted a linearly-polarised blue luminescence. The most recent report demonstrates in a diamond a one to one correspondence between dislocations (as revealed by X-ray topography) and the blue-emitting lines (see Fig. 1); this proves beyond doubt that they are dislocations.

Features that appear in Fig. 1*b* but not Fig. 1*a* are dislocations which are too deep in the crystal to be observed in cathodoluminescence. Features in Fig. 1*a* that do not appear in Fig. 1*b*, although linear, are not dislocations. Their emission is not polarised and does not saturate in intensity with increased electron beam current, unlike the dislocation lines.

One problem with cathodoluminescence in the topographical examination of crystals is that it is limited to a layer within 100 μm of the surface by the penetration depth of the electrons. Consequently crystals need to be cut according to the surface to be studied. Furthermore, the crystal must be transparent to the emitted radiation. Diamond is ideal in this respect, because it transmits well into the ultraviolet, and can therefore be examined visually.

A great advantage of cathodoluminescence is its power of discrimination. Different types of feature can be distinguished easily. The possible variables are colour (blues, greens, yellows and pinks have been observed so far), polarisation of the light, and variation of luminescent intensity with electron beam current (some features saturate, others do not). No doubt cathodoluminescence will be used a great deal in the future for the study of dislocations and growth features in crystals. □

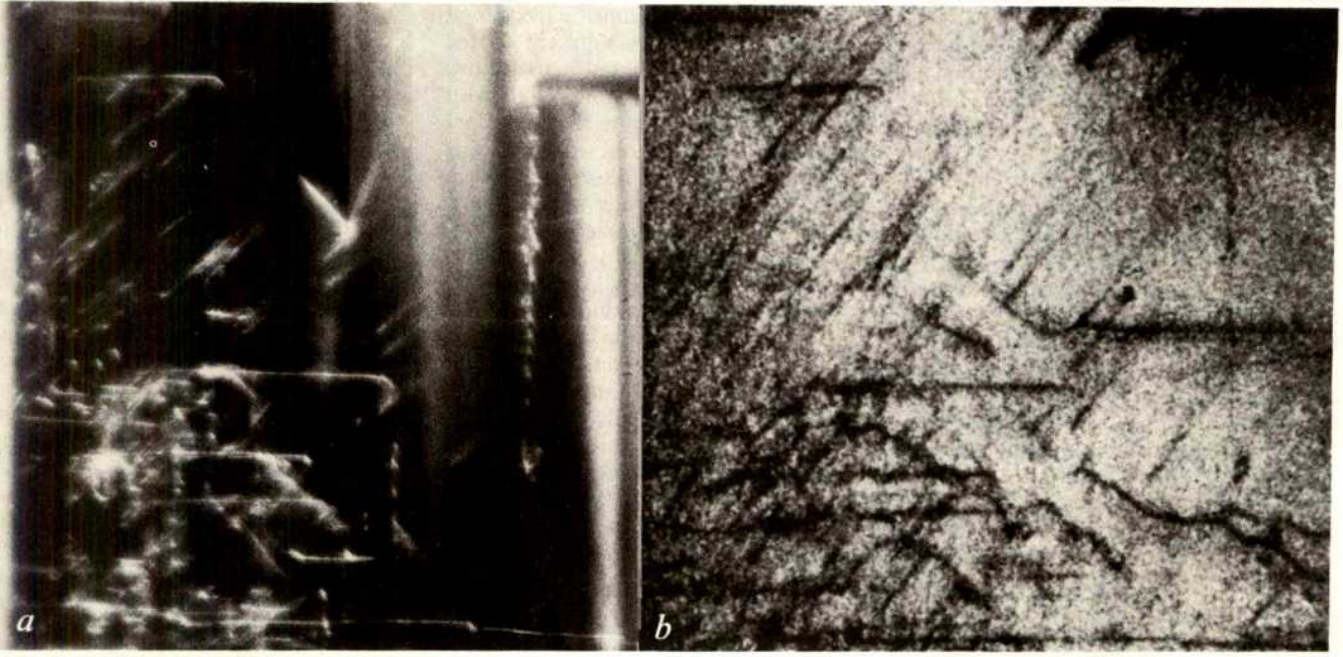

Fig. 1 Correspondence between cathodoluminescence images (*a*), and X-ray diffraction contrast images (*b*), of individual dislocations in a natural diamond.

How closely did the continents fit together?

from A. Hallam

A FUNDAMENTAL tenet of plate tectonics, that amount of crust created at oceanic ridges must equal the amount subducted elsewhere, has recently been challenged in a stimulating paper by Owen (*Phil. Trans. R. Soc.*, **A281,** 223; 1976). He has argued that the components of Wegener's supercontinent Pangaea moved apart as a consequence of 20% expansion of the Earth's diameter since the early Jurassic, less than 200 million years ago. This iconoclastic view is very radical in terms of physical theory and is no more likely to be widely accepted than the similar view put forward some years ago by the Australian geologist Warren Carey. Bearing in mind the unfavourable reaction to Wegener's continental drift hypothesis earlier this century, and its subsequent history, it behoves earth scientists to preserve an open mind on such matters, but they have the right to demand compelling evidence in favour of earth expansion and a clear demonstration of the inadequacy of current global tectonic theory.

It can hardly be said that Owen is especially convincing on either count, which is not to say that he makes no telling points. The gist of his argument is geometric, that the celebrated Bullard fit of the Atlantic continents, and its successors such as the Smith and Hallam fit of the Gondwana continents, pose awkward problems of continental overlap and misfit which have not been adequately explained away. For example, many geologists have been worried by the loss of much of Central America in the Bullard fit, despite the fact that extensive areas of old continental rocks occur there, and attempts to get round this problem by seemingly arbitrary *ad hoc* tectonic displacements and rotations, have lacked plausibility.

Likewise, if one adopts the Smith-Hallam fit, West Antarctica does not run naturally into its obvious geological continuation in Patagonia. More disturbing perhaps, a large gap is left west of Australia, which has led to the suggestion that the Wharton Basin in that region was ancient ocean, now disproved by the Deep Sea Drilling Project which has demonstrated that the basin is underlain by oceanic crust as young as elsewhere. On the other hand, fitting India against Australia, as others have done, leaves a corresponding gap in the western Indian Ocean.

Such problems can indeed be resolved, as Owen points out, by extremely rapid Earth expansion, but before leaping to such a drastic conclusion it is worth looking more closely at the original computer least squares fit pioneered by Bullard and his colleagues. This and subsequent fits were taken at the 500 fathoms (~1,000 m) contour for purely geometric reasons, because this gives the best fit and usually lies on the steepest part of the continental slope and is therefore well defined. It is only strictly valid if it coincides closely with the boundary of continental and oceanic crust, but geological and geophysical evidence has been accumulating that this is not the case.

Thus Talwani and Eldholm (*Bull. geol Soc. Am.*, **83**, 3575; 1972) argue persuasively that the extensive Voring Plateau off Norway, with an average depth of 2,000 m, is subsided and thinned continental crust. Similarly, Jansa *et al.* (*Geol. Surv. Canada Pap.* **74–30**, 51; 1975) make a convincing case for a wide zone off the Nova Scotia, eastern Newfoundland and north west African shelves as subsided continent, and suggest that the 3,500 m contour is a geologically more realistic estimate of the true continental edge. Very similar evidence and arguments have been put forward for the region offshore of Angola by Burollet and Byramjee (*Notes Mém. Comp. Fr. Pétroles*, no. 11, 71; 1974), leading to the same conclusion. An important implication is that a sector of subsided and attenuated continent well over 1,000 km wide in places must exist between Africa and America, and that the so-called Quiet Magnetic Zone is not entirely oceanic, as hitherto almost universally accepted by marine geophysicists.

A hundred years ago

VARIOUS sanitary measures (according to Dr Tholozoan) have recently been adopted by the Turkish and Persian Governments with reference to the outbreak of plague, which commenced in Mesopotamia in the early part of the year. Since the beginning of March a sanitary *cordon* has been established on the north of the invaded territory, on the most frequented route of Kurdistan and Syria, between Tecrit and Kilfri. On the south a quarantine of fifteen days is obligatory since April 1 on all vessels sailing on the Tigris and the Euphrates It is at Kourna, at the confluence of these rivers. The ports of the Persian Gulf are protected by a quarantine which vessels from affected localities have to undergo at the island of Kezzer, formed by junction of the Chotel Aral and Karoun. Since April 10 all communications by land between Persia and Mesopotamia are subject to a quarantine of fifteen days. For three years, it may be added, all pilgrimages into the infected country, by Persian subjects, have been interdicted.

from *Nature*, **14**, July 6, 218; 1876.

Burollet and Byramjee extend their zone of subsided continental crust round to the East African offshore zone and elsewhere, which has a significant bearing on the arguments recently put forward by Kent and Tarling (*Nature*, **261**, 304, 1976) against a fit of Madagascar snugly against Kenya and Tanzania. This they dismiss as implausible because of the known extent east of these mainland countries for hundreds of km of a thick sequence of late Palaeozoic and younger shallow marine and continental sediments. Kent and Tarling treat this as an argument for a more southerly former position of Madagascar, thereby dismissing without obvious justification palaeomagnetic evidence to the contrary, instead of appreciating that all that may be at fault is the geologically implausible tightness of fit if the 500 fathom contour is used. In this connection it is interesting to note that some new palaeomagnetic data just published supports the northerly fit for Madagascar (McElhinny and Embleton, *Earth planet. Sci. Lett*, **31**, 101; 1976).

Much more research on continental margins around the world will have to be undertaken before an accurate new continental fit can be reliably attempted, but already it seems likely that most if not all of the apparent geological inconsistencies of the older fits wil magically disappear, and the Tethys will not seem such an awkwardly eastward gaping ocean. ☐

Future of space science

from S. I. Rasool

A symposium on the Future of Science in Space was held as part of the 18th COSPAR meeting which took place in Philadelphia on June 7–18, 1976.

THE future of space science is becoming a matter of grave concern to the space scientist. The national space science budgets have considerably declined in their buying power and for the large pool of space experimenters in the Western world opportunities seem to be few. At the same time the exploratory phase in many disciplines is over. The days are long gone when a simple magnetometer, a geiger counter, or a TV camera flown anywhere in space or to a nearby planet would make an instant discovery Although the potential for major discoveries about the Universe is still great in some of the fields (such as infrared, ultraviolet and gamma ray astronomy) the emphasis in space science is going to be more towards "why" than "what". This immediately implies more sophisticated and correlative experiments in space, large space telescopes and observatories to study the remote regions of the Universe and more detailed study of the planets with orbiters, landers and probes rather than with flybys.

What are the chances that space science will progress at the same vigorous pace as it has done over the past two decades? What should be the major thrusts and priorities? What are the national policies towards space science? These were some of the questions discussed in a one and one-half day symposium and panel discussion convened by COSPAR (International Committee on Space Research) during its recent meeting.

If the objective of the organisers was to get a unified view of things, the meeting was a disappointment. Six individuals from six different countries not only gave a variety of views but made six different kinds of presentations. They ranged all the way from topical and systematic descriptions of future thrusts in space research to a philosophical discourse on the art of extrapolation and on the meaning of utopia. A few themes did recur and are noteworthy space research in the future will be more focused and will need more justification; with the advent of the Shuttle, the cost of doing science will, it is hoped, go down; space science cannot survive in isolation, it should be integrated with classical disciplines in science; high energy astrophysics has a great future in space and the Space Telescope is the next logical step in optical astronomy; the scientific aspect of remote sensing of the earth will be emphasised more, while considerable thought should be given to studying the planets from earth orbiting telescopes.

Representatives from the European Space Agency (ESA) and NASA who joined the speakers for the panel discussion sounded optimistic about the future of space science in the total programme. ESA has a new science advisory structure to optimise the science input in the programme planning. NASA views space exploration closely tied to the biological imperative—the challenge of the unknown—and therefore a vigorous programme of space science and exploration has been and will be supported by the American public. A large Space Telescope, high energy observatories, probes to planets and a possible sample return from Mars may be the highlights of the US space science programme in the next decade. It appeared from the statements of the Soviet representatives that the Soviet emphasis on Venus will continue. In space astronomy, radio interferometry may be emphasised and in magnetospheric physics, active experiments to understand plasma interactions. An earth surface mineral resources survey was also mentioned by the Soviet scientists.

What was really accomplished at this Symposium is not clear and apparently not many people expected much to happen either: of the 600 or so participants at this year's COSPAR, the audience for this Symposium probably never reached the 100 mark. ☐

Trees in the tropics

from P B. Tomlinson

> The Fourth Cabot Symposium held at Harvard Forest, Harvard University, April 26–30 had as its subject Tropical Trees as Living Systems.

An appreciation of the need for an understanding of tropical forests in terms of the individual diversity of tree species was the theme of the Symposium The enormity of this task is indicated by the floristic diversity of woody plants in the tropics In Malaysia, for example, M. E. D. Poore (*J Ecol.*, **56**, 143–196; 1968) found in a survey of 23.0 ha, 2,773 tree-sized individuals with a trunk girth greater than 91 cm, representing 375 species, 139 genera and 52 families. To obtain an equivalent diversity in a temperate flora one would have to map an area equal to a quarter of the United States. The systematic assessment of tropical tree floras is still incomplete, while most aspects of structure, growth, function, reproduction, and ecology remain uninvestigated. Generalisations about the biology of woody plants are still determined with temperate trees in mind, the more balanced view which might be obtained if tropical species were better understood has yet to be established. Consequently the uniqueness of this symposium was its examination of the tree as an individual, with a focus on many functional processes, and its attempt to deal mainly with tropical examples. The programme was so arranged that a gradual progression from a detailed consideration of construction and physiology led naturally to an appreciation of the tropical forest as a complex of interacting and highly diverse units. The result was an overview of our current understanding of aspects of the biology of tropical trees and the proceedings which are to be published should stimulate research on woody plants in the tropics.

Early sessions dealt with evolution, genetic diversity, and especially morphological patterns of organisation. The broad perspectives sought were indicated by the opening discussion of palaeobotanical evidence for the evolutionary origin of tropical trees and forests by J. Doyle (University of Michigan) which made the point that a better understanding of functional morphological relationships of leaf architecture would permit more conclusive palaeontological evaluation of theories of vegetative evolution in angiosperms. It was, therefore, appropriate that there should be a subsequent discussion of the adaptive significance of compound leaves by T. Givnish (Harvard University). This kind of interaction occurred throughout the meeting.

Tree architecture provided a framework for ample discussion, with emphasis on different kinds of trunk-branch axis differentiation in producing optimum patterns of leaf arrangement. The way in which the tree can often be regarded as a modular composition of equivalent units was emphasised by M.-F. Prévost (ORSTOM, Apiodoumé, Ivory Coast). Of the many examples of crown construction presented, none was more distinctive than that of the genus *Araucaria*. In New Caledonia J M Veillon (ORSTOM, Noumea) showed that most species produced repeating crowns since the first generation of branches developed by the trunk is succeeded by two or more subsequent ones originating from late-developing branches, the successive crowns overlapping each other like a nest of coffee tables. The need for a better appreciation of the complex hormonal control of branch expression was emphasised by A. Longman (Unit of Tree Biology, Institute of Terrestrial Ecology, Edinburgh) and G. Browning (University of Wales, Aberystwyth) but no better indication of the resulting regularity which is possible was found than in the quantitative analysis of *Terminalia* by J. B. Fisher (Fairchild Tropical Garden, Miami). This represents the first such precise analysis of a crown form familiar to tropical travellers and further demonstrated another common theme of the symposium, that quite simple methods and approaches can generate important new ideas. At the same time modern technology has its place, as was shown by R. Borchert (University of Kansas) whose computer simulation of shoot extension, based on known examples, suggests the existence of endogenous control of rhythms of shoot extension. Tropical trees are not necessarily subject to marked seasonal variation in climate and why shoot growth is usually not continuous is intriguing.

In the area of reproductive biology F. Ng (Forest Research Institute, Kepong) showed a greater diversity of seedling morphology in the tropics than the terminology devised for temperate trees can accommodate, with the obvious ecological implication of successful tree establishment as the basis for his study. The strategies that tropical trees have evolved in the evasion of seed predators were discussed by D. H. Janzen (University of Michigan). Predator pressure can be enormous and it was reassuring that J. Sarukhán (Universidad Nacional Autónoma de Mexico) could find survivors enough to make demographic studies of continuing populations of forest trees.

The several speakers who attempted an analysis of the forest itself were unanimous in presenting it as a dynamic system. R. A. A Oldeman (Mission ORSTOM, Ecuador) provided a provocative view of the forest as a population of trees whose developing architecture was the result of their individual ability to adapt to available energy levels through repeated cycles of growth. A contribution in which the data had been collected by University students (P. A. Ashton, University of Aberdeen) was particularly welcome since the tropical rain forest is an ideal training ground for future ecologists.

In all, 28 speakers from 13 countries participated. Such an overview is timely in view of the current rapid destruction of tropical forests, which was commented on repeatedly. At present the rate of increase in our understanding of tropical ecosystems is far exceeded by the rate of their destruction. Any corrective influence is appropriate. ☐

review article

Quasars and the cosmological distance scale

M. Rowan-Robinson*

There has been continuing controversy about the distances of the quasars since their discovery 13 years ago. Here one of the proponents of the view that at least some quasars are "local" explains why he now believes quasar redshifts are cosmological.

Twice this century the cosmological distance scale has been the subject of famous debates. In 1920 Shapley and Curtis[1] debated whether the spiral nebulae formed part of the Milky Way system. Fifty-two years later, in December 1972, Arp and Bahcall[2] debated whether the redshifts of quasars are cosmological.

Both debates were inconclusive at the time. Shapley was correct in his estimate of the vast overall dimensions of our Galaxy: but on the question at issue he was wrong. In the second debate interesting and suggestive arguments (and not a few weak ones) were presented both for the "cosmological" and "local" interpretations of quasar redshifts, but neither proponent was persuaded to yield ground. A compromise solution, that two types of quasar exist, one type local, the other cosmological[3], was unacceptable to both. Has the balance of the evidence shifted in the past three years? I believe that it has, and in this review I will try to explain why. For a more complete bibliography, the reader should consult Field *et al.*[2] and the more recent article by Burbidge[4], whose conclusions are the opposite of those expressed here.

The 1972 Arp–Bahcall debate rested on 7 main kinds of argument; (1) the redshift–distance relationship for normal galaxies, (2) continuity between quasars and other types of active and compact galaxy, (3) quasars in the directions of galaxies and clusters of galaxies with the same redshift as the quasar, (4) quasars in the same direction as bright galaxies of much lower redshift, (5) luminous filaments connecting galaxies and quasars with very different redshifts, (6) the overall distribution of quasars on the sky, (7) non-velocity redshifts in normal galaxies.

While the anomalies (4)–(7) have been neither impressively augmented in the interim, nor decisively eliminated, the evidence under (1) and (2) has strengthened considerably.

The redshift–distance relationship for normal galaxies

In a classic series of papers Sandage and Tammann[5-11] have put the redshift–distance relationship discovered by Hubble and Lundmark on to a solid basis, and have removed the possibility of any strong deviation from this linear behaviour within 200 Mpc.

In the first two papers[5,6], galaxies of the Local Group and of the nearby M81 group (3.25 Mpc away), for which distances can be established from Cepheid variable stars (assuming the known distance of the Hyades cluster), are used to calibrate two methods that can be used for more distant galaxies: the optical size of the largest H II regions in galaxies and the luminosity of the brighest stars in a galaxy. In both cases the quantities to be used as distance indicators depend on the luminosity and type of galaxy concerned, and this dependence has to be obtained from these nearest galaxies. In the third paper[7] those two methods are used to determine the distance of the M101 group of galaxies (7.2 Mpc), important because it provides the nearest example of an Sc galaxy of luminosity class I. van den Bergh[12] found that the appearance (surface brightness, degree of development) of spirals arms is correlated with the luminosity of the galaxy, and may be used to provide a luminosity classification of spiral galaxies. In the fourth paper[8] the same two methods are used to get the distances of 39 Sc galaxies with distances in the range 3–20 Mpc, and hence to calibrate the van den Bergh luminosity classes. In the fifth paper[9] distances to groups of galaxies within 30 Mpc are determined both by the H II region method and by Sc luminosity classes. The latter method is also used for more distant galaxies (to 50 Mpc). A convincing redshift–distance relation is obtained, the constant of proportionality being $H_0=57\pm3$ km s^{-1} Mpc^{-1} (the Hubble constant) and this linear relationship is "not only as isotropic as it can presently be determined (3σ $[\Delta H/H]\simeq 30\%$), but the flow is also as *quiet* as we can measure it". In fact Sandage and Tammann allow only $\sigma(\Delta v)\lesssim 50$ km s^{-1} as "a generous limit for the mean random motion" (of galaxies about the Hubble flow). In the sixth paper[10] the authors use a sample of remote Sc I galaxies (out to 200 Mpc) to determine $H_0=55\pm6$. Finally Sandage[11] uses a further remote sample of galaxies, from the Southern Hemisphere, to check the isotropy of the Hubble flow.

Sandage[13] had earlier shown, continuing the programme of Humason, Mayall and Sandage[14], that the brightest galaxies in rich clusters show a good correlation between magnitude and redshift, consistent with the Hubble relation together with the assumption that the luminosity of the brightest galaxies in clusters are all the same. This pushes the frontier to which the Hubble law has been tested to almost 3,000 Mpc.

Sandage and Tammann have concentrated on the four distance methods: Cepheids, H II regions, bright stars and Sc luminosity classes. van den Bergh[15] reviews distance estimates to the nearby Magellanic clouds by 11 different methods and shows that the methods broadly agree with one another. He also reviews the results of 12 methods of determining H_0 and arrives at a weighted mean of 93 ± 7. Most of these methods have, however, large uncertainties and the Sandage and Tammann value of 55 is within $2.6\,\sigma$ of all of them. It is also not clear that most of these methods have been calibrated with the same care as the Sandage and Tammann programme, especially for correlations of the chosen indicator with galaxy type and luminosity. The most important alternative method is one based on the expansion rate of supernovae[16], which is completely independent of the whole elaborate distance ladder built up from the Hyades cluster. This yields $H_0=60\pm15$,

---

*Queen Mary College, Mile End Road, London E1 4NS, UK

an impressive and rather remarkable confirmation of the Sandage and Tammann distance scale.

Dissenting points of view

Three of the main dissenting points of view focus on the questions of calibration, the Local Supercluster, and the so-called Rubin–Ford anomaly. The sceptic might also ask a fourth question: will the Hubble constant be reduced further?

Two criticisms have been directed at Sandage and Tammann's calibration of their distance scale Madore[17] has argued that additional corrections need to be applied to the determination of distances using Cepheid variables, which would have the effect of increasing H_0, and Denmat *et al.*[18] claim that with the Sandage and Tammann Sc luminosity class calibration, H_0 is different when determined by galaxies in different classes. If van den Bergh's original calibration is used, however, this difference disappears: an embarrassing side effect is then that H_0 decreases with distance. A dependence of the Hubble constant on distance had earlier been claimed by de Vaucouleurs[19].

Because of the rather small number of galaxies available for the calibration of each luminosity class, it is rather difficult to decide between an incorrect calibration of the relative luminosity of the different classes, and a dependence of H_0 on distance. The linearity of the magnitude–redshift relationship for brightest cluster galaxies[13] shows that such a dependence can only occur for distances nearer than the Virgo cluster, which fits well on to the relation for other clusters. An important argument against a dependence of H_0 on distance is therefore that the value of H_0 determined from the Virgo cluster alone[8] agrees well with that determined from all nearby galaxies.

The second issue is the long standing one of the local supercluster. de Vaucouleurs[20] has argued that the prominent band of galaxies across the north Galactic pole and passing through the Virgo cluster constitutes a disk-like "supercluster" of galaxies with the centre at Virgo and ourselves at one edge. The Sandage and Tammann programme deals a severe blow to this hypothesis, since they find no deviation from the linear Hubble flow correlated with direction along the supergalactic plane, or towards and away from Virgo. Jones[21] has argued that the local galaxy distribution can be understood in terms of Virgo being a rich cluster of normal dimensions (diameter $\sim$ 4 Mpc, instead of $\sim$ 40 Mpc for the supercluster). de Vaucouleurs has, however, reiterated his case for the existence of the supercluster, using evidence from nearby galaxies[22], hydrogen clouds[23], groups of galaxies[24], and clouds of galaxies[25]. In each case the number of objects seems rather small for a significant determination of distribution on the sky. A further problem is the strong effect of galactic obscuration below galactic latitude b=40°, so that only about one third of the sky can be studied in a relatively unobscured direction.

Third, cosmologists have been perplexed by the Rubin-Ford anomaly. Rubin, Ford and Rubin[26] studied a sample of 50 Sc I galaxies with $14 \lesssim m_{pg} \lesssim 15$, and $4{,}000 \lesssim v \lesssim 7{,}500$ km s^{-1}. They found different mean velocities for two hemipheres of the sky corresponding to a velocity of 700 km s^{-1} for the Solar System relative to these galaxies. Since our velocity relative to the microwave background is $\lesssim$ 300 km s^{-1} (ref. 27), a paradox of Michelson–Morley proportions seemed to be emerging. Jaakola *et al.*[28] claim a difference in the redshift distribution for compact galaxies with absorption spectra, over the two Rubin–Ford hemispheres, but only at the 2σ level.

Sandage and Tammann[9] find no evidence for a difference in H_0 between the two hemispheres when velocity-limited samples are studied. They conclude that the effect is due to the bias introduced by a magnitude-limited sample of a population in which there is an appreciable spread in the luminosity. Hartwick[29] discusses the contribution of interstellar absorption to such an effect.

Finally, the value of H_0 first given by Hubble[30] was 500, since when the accepted value has been steadily reduced. Have we reached the end of the road, or will there be yet another downward revision in a decade's time? Tammann[31] explains why the corrections have always tended to be downwards: "one is basically reluctant to accept the existence of objects which are much brighter and much larger than those one has previously experienced in the immediate neighbourhood". The value $H_0 = 55$ leads to an expansion time for the Universe, if the redshift is interpreted as due to recession, of 1.9×10^{10} yr, compared with the age of our Galaxy of 1×10^{10}–1.5×10^{10} yr, fitting in well with the idea of a 'big bang' universe in which galaxies form early on.

(There is, unfortunately, no direct evidence for interpreting the redshift as due to recession. The success of the big bang picture in explaining the microwave background, the primordial abundances of He and D, and the age of our Galaxy, constitute powerful indirect evidence Most of the discussion of this article is independent of the interpretation of the redshift.)

At present it is hard to imagine H_0 lying outside the range 30–100, but there are two arguments which might eventually force a lower value If the local supercluster could be shown to be a real object 40 Mpc in size, then for it not to be the largest cluster in the Universe, H_0 might have to be as low as 10. But the recession velocities of local supercluster galaxies would then be anomalously large. Second, the revision of stellar evolution theory needed to explain the low solar neutrino flux could substantially increase the life of stars on the main sequence, and hence the age of the oldest stars in the galaxy.

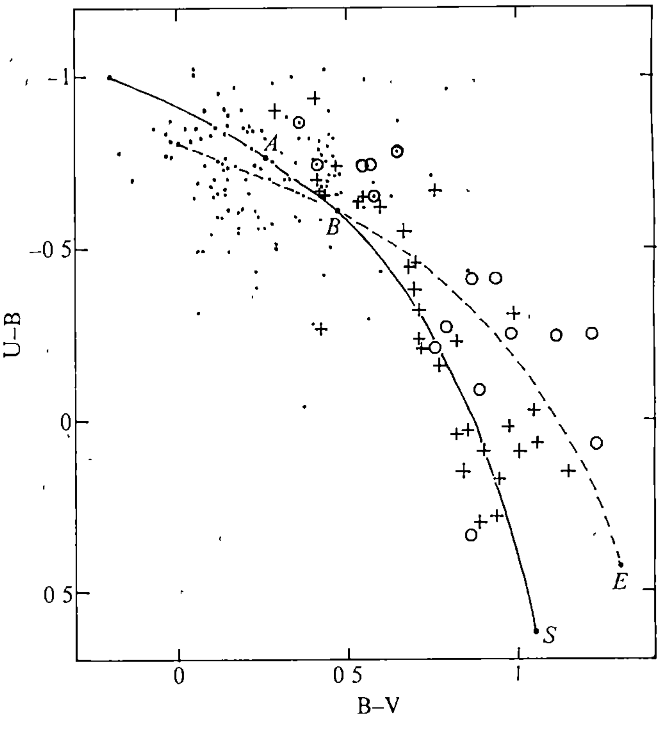

Fig. 1 Colour–colour (U–B against B–V) diagram for quasar (●, ref 40), N galaxies (○, ref 37) and Seyfert galaxies (+, refs 38, 39), together with mixture lines calculated by combining the light of a normal galaxy with that of a quasistellar nucleus, in different proportions (spiral at $z = 0$, B–V = 1.05, U–B = 0.62; solid curve (ref 38), elliptical at $z = 0.1$, B–V = 1.3, U–B = 0.53: broken curve (ref 37)) The circled dots at (0.36, –0.87), (0.58, –0.65), (0.41, –0.74), (0.64, –0.78) denote B46, B264, B340 and Ton 256, respectively, which have been classified as quasars, but which are fuzzy The points labelled *A* and *B* on the spiral and elliptical loci, respectively, denote the points at which the visual light from the quasistellar core equals that from the galaxy No Seyferts are found to the left of *A* and no N galaxies are found to the left of *B*

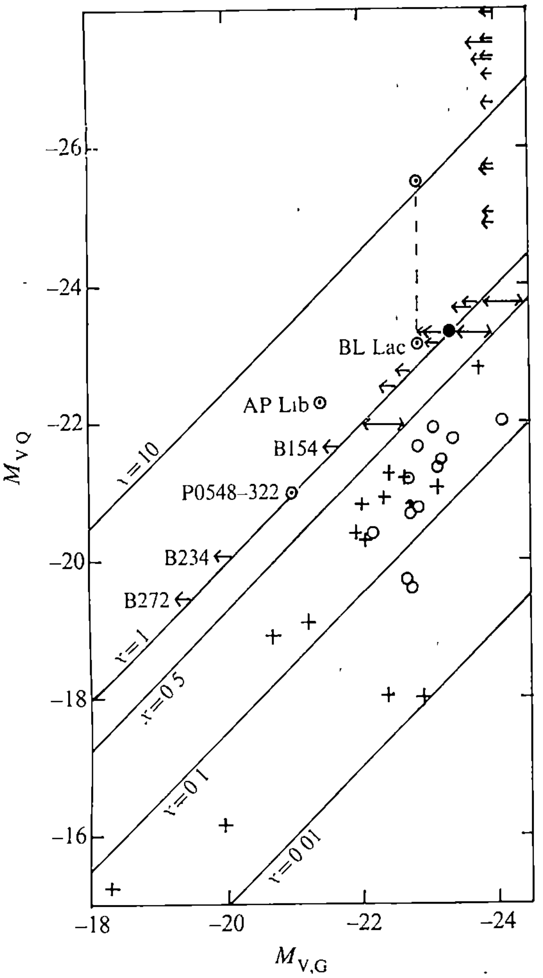

Fig. 2 Comparison of the absolute visual magnitudes of the quasistellar ($M_{V,Q}$) and galaxy ($M_{V,G}$) components in Seyferts (+, refs 38, 39, 42), N galaxies (○, ref. 37), BL Lac objects (⊙, refs 43–46) and optically selected QSOs (Ton 256 as filled dot, rest as arrows, refs 40, 47, 48). The redshifts of QSOs have been assumed to be cosmological, and H_0 has been taken as 50. Lines of constant $x = p_{oc}/p_{og}$, the ratio of the visual light from the core to that from the surrounding galaxy, are shown B46, B264, B340, which are fuzzy, are shown as having $0.5 \leqslant x \leqslant 1$, and the rest of the QSOs are shown with $x \geqslant 1$ or $M_{V,G} \geqslant -24$, the highest luminosity attained by galaxies.

Continuity between quasars and galaxies

The similarities between quasars and the nuclei of N galaxies and Seyferts have been commented on by many authors[32-36]. Sandage[37] showed that the colours of N galaxies as a function of aperture could be understood in terms of underluminous QSOs in the nuclei of normal giant elliptical galaxies. Weedman[38] and Penston *et al.*[39] have shown a similar relationship between Seyfert nuclei and spirals. Fig. 1 shows the colour–colour diagram for quasars, N galaxies and Seyferts, together with the loci obtained by adding quasars of different luminosity to normal elliptical and spiral galaxies.

Kristian[41] showed that amongst low redshift quasars, those with lower optical luminosity (assuming the redshift to be cosmological) tended to be fuzzy, while those of higher optical luminosity appeared stellar, which would be consistent with the idea of an underlying giant elliptical galaxy. Figure 2 compares the optical luminosities of the quasistellar (p_{oc}) and galactic (p_{og}) components in quasars, N galaxies and Seyferts. We suppose that quasars whcih have been described as fuzzy lie in the band $x = p_{oc}/p_{og} \sim 0.5$–$1$. If $x \gtrsim 1$ the object appears entirely stellar and is called a quasar. if $x \lesssim 0.5$ the object is sufficiently fuzzy to be called an N galaxy or Seyfert. In between there is a domain of uncertainty where objects are classified as quasars or N galaxies by different observers (for example, Ton 256, B264).

The BL Lac objects

The most interesting development of the past few years has been the discovery of the BL Lac objects. These are strong variable radio sources identified with QSOs of neutral colour, in which the spectra show no emission lines[49]. This seems to be due to a steep decline with increasing frequency of the optical continuum (also responsible for the neutral colours), with a consequent deficiency of ultraviolet photons to excite the lines[43] They are therefore simply quasars without an ultraviolet excess.

Table 1 lists the properties of the BL Lac objects identified to date. Oke and Gunn[43] succeeded in measuring the spectrum of the galaxy underlying BL Lac, with a redshift of $z = 0.07$. Baldwin *et al.*[50], however, failed to find any features in their spectrum of BL Lac. Thuan *et al.*[44] confirmed the redshift of $z = 0.070 \pm 0.005$, on the basis of several normal galaxy lines and bands. It would be clearly desirable to have this result confirmed by independent observers. Other BL Lac objects which have had redshifts determined are P0735+178[51], P0548−322[45], AP Lib[46] and B2 1101+38[52]. The separation into galactic and quasistellar components has been performed for BL Lac[43], P0548−322[45] and AP Lib[46], and they are included in Fig. 2. For AP Lib, $x \sim 3$, and for BL Lac, $x \sim 10$ when observed by Oke and Gunn[43], so these objects are firmly into the quasar band in Fig. 2. The identification of underlying galaxies in these objects is therefore one of the strongest pieces of evidence that quasars occur in galaxies. The high optical luminosity achieved by BL Lac at maximum removes any rationale for treating the quasars with flat spectrum, compact radio sources as a local population with properties similar to the low luminosity sources seen in Seyfert nuclei[3]. This type of activity is clear possible over a wide range of luminosity, up to the range seen in quasars, and no advantage is gained by the "local" hypothesis.

The strong variability of some quasars and BL Lac objects suggests that they may sometimes be found in a quiet phase, with $x \lesssim 1/2$, that is, becoming N galaxies. Spectra and photographs taken at these phases should show evidence of an underlying galaxy. Figure 2 shows, however, that the notion that QSOs are only to be found in giant ellipticals should be dropped. B154 and B234 show no fuzz even though they are respectively 1.6 and 3.2 magnitudes fainter than the mean for brightness cluster ellipticals. These QSOs can be occurring only in galaxies of modest optical luminosity.

Finally the case of 3C48 should be mentioned. Wampler *et al.*[74] succeeded in detecting emission lines from hot gas associated with the nebulosity surrounding this quasar. The lines are narrower, and have a slightly larger redshift, than those of the central quasar, thus ruling out the gravitational redshift. The high optical luminosity of 3C48 ($M_v = -25.5$) makes it unsurprising that an underlying galaxy was not detected.

Associations on the sky

Arp[2] has emphasised how apparent associations on the sky have an important role in establishing the conventional distance scale for galaxies. Groups and clusters of galaxies seen in a particular direction on the sky are normally assumed to be at the same distance.

Several quasars of low redshift have been found to be "near" galaxies and groups of galaxies of the same redshift (Table 2*a*), presumably establishing the cosmological nature of the redshift in these quasars (but this is disputed by Burbidge and O'Dell[89]). It is unfortunate that all the clearcut cases of this type are quasars with extended double radio sources, for which the continuity of the radio dimensions with those in radio galaxies and the fall off of angular size with redshift already support the cosmological interpretation

The best case involving a compact radio-source quasar is 4C11.50B = 1548+115a[90], but here two quasars are found near a group of galaxies[91,92], one with the same redshift as the group[80], one much larger, and it is unclear which is responsible

Table 1 Properties of BL Lac type objects

Name	Redshift	B	B–V	S(5GHz) (Jy)	α(5GHz) [$S(\nu)\alpha\nu^{\alpha}$]	Refs for data	$M_{V,Q}$	$M_{V,G}$	log P(5 GHz) (W Hz^{-1})

The spectral indices are taken from ref. 62.

The luminosities given in the last 3 columns are calculated assuming $H_0 = 50$.

Note added in proof: Twelve further possible BL Lac objects are given by Kinman[125]. E M Burbidge *et al.*[126] have measured the absorption time redshift of AO 0235+164 as 0.5240, with a possible second system corresponding to $z = 0.85$.

for the associated extended double radio source. Argue *et al.*[90] propose that the double source, as well as the compact source, is associated with the smaller redshift quasar, but the centroids of the two emission regions are accurately aligned with the high redshift quasar. Clearly it is important to find unambiguous examples of low redshift, compact radio-source quasars in groups or clusters of galaxies.

Many examples have also been given of quasars "near" comparatively nearby galaxies, of much lower redshift than the quasar (Table 2*b*). Arp and G. R. Burbidge have been the strongest proponents of the arguments that these associations are real and that the redshifts of many or all quasars include a substantial intrinsic component. *Post hoc* calculations of the probability of these associations have been adduced as support for this interpretation[2,93], but all such calculations are fallacious from a philosophical point of view. Evidence that such associations are real must be of a statistical nature. A chosen large sample of bright (peculiar?) galaxies must be selected in advance, together with a comparable random set of positions on the sky as a control. Regions of the same size should be searched round each position in the two samples for quasars, and the redshifts determined. In this way clearcut evidence that quasars are to be found around bright galaxies can be obtained.

The number of close associations found to date is not especially remarkable. The number of quasars on the whole sky, N, brighter than magnitude B_Q and within 2′ of a galaxy brighter than m_G, is roughly

$$\log_{10}N \simeq 2.9+0.75(B_Q-20)+0.6(m_G-15.7)$$

using Sandage and Luyten's[94] $N-m$ relation for QSOs and the fact that there are on average about 1.6 galaxies per square degree in the Zwicky catalogue[95]. At present perhaps 1–2% of the sky has been searched for associations between quasar and Zwicky galaxies, giving a prediction of 8–16 such associations as compared with the 12 given in Table 2.

Two cases of pairs of quasars very close together (Ton 155, 156, 35″ apart[96]; 4C11.50a,b, 5″ apart[91,92]) have been given. It is interesting that Stockton[80] has found a galaxy near 4C11.50

Table 2 Associations of quasars with galaxies

Year	*a*, Associations with galaxies of the same redshift	*b*, Associations with galaxies of different redshift (within 2′ arc)
1969	B264 in cluster with $z = 0.095$ (75)*	1108+285 1.1′ from NGC3561 (81)
1970		Mark205 42″ from NGC4319 (82)
1971	P2251+11 in cluster with $z = 0$ 323 (76)	3C232 1.9′ from NGC3067 (83)
	Ton256 in cluster with $z = 0.131$ (76)	PHL226 0.8′ from ICI746 (83)
1972	3C323.1 in cluster with $z = 0.264$ (77)	3C455 23″ from NGC7413 (84)
		P1021−0.0 1.9′ from Zwicky galaxy (89)
		P2020−37 0 15″ from galaxy (86)
1973	RN8 (near 3C61.1) in cluster with $z = 0.184$	P0038−01.9 1 2′ from Zwicky galaxy (61)
	4C37 43 associated with galaxy $z = 0.370$ (79)	P0823+03 3 1.7′ from Zwicky galaxy (61)
1974	4C11 50a near galaxy with $z = 0.436$ (80)	
1975		Quasars 76″ from IC1417, 95″ from NGC5682 (87)
		QSO 58″ from IC2402 (88)

*Numbers in parentheses are ref. numbers.

with the same redshift as the low redshift quasar. Many more examples would have to be found (and again, in a well-defined search programme) to constitute evidence that these are real associations.

The situation on luminous filaments connecting galaxies with very different redshifts[2,97-101] remains inconclusive. Walker *et al.*[102] find no clear luminous connection between NGC4319 and Markaxian 205, or between the members of Seyfert's Sextet. They confirm the reality of the arm linking NGC7603 to its companion, but find no evidence of interaction.

Other evidence

Among the additional arguments cited in favour of the cosmological interpretation of quasar redshifts are (1) the decline with redshift of the maximum separation found in extended double radio sources in quasars[103-107] (2) H I absorption in quasars which may be due to an intervening gas cloud[108,109] (3) interpretation of some ultraviolet absorption lines as due to molecular hydrogen between us and large redshift quasars[110,111] (4) various claims of correlations of optical and radio brightness with redshift (of somewhat doubtful significance in view of the wide range of quasar radio and optical luminosities).

Supporting the "local" interpretation are (1) periodicities in the redshift distribution of quasars (and radio galaxies)[115-117] (2) excess redshifts in normal galaxies[118-122] (3) rapid radio variations requiring ultrarelativistic velocities[123] (such motions are anyway required in some radio galaxies and to understand multiple absorption redshift in quasar spectra).

None of these arguments seems really decisive either way.

Conclusion

The establishment of the redshift–distance relationship for galaxies on what seems to be an impregnable basis, to the extent that any "intrinsic" redshift effect cannot exceed 50 km s^{-1}, and the evidence that QSOs occur in galaxies and with luminosities at least ten times that of the galaxy, removes any doubt from the present author's mind that the redshifts of quasars are cosmological. Certainly there no longer seems to be any strong reason for maintaining that quasars with compact radio sources are local[3,124]. While efforts to detect galaxies believed to underline quasars, and to find associated groups of galaxies, should clearly continue, supporters of the "local" hypothesis have to meet the challenge of pursuing a well defined, unbiased, controlled programme to demonstrate statistically the association of quasars with relatively nearby galaxies. On the present evidence I believe that such a programme will fail.

The Karari Industry: Early Pleistocene archaeological evidence from the terrain east of Lake Turkana, Kenya

John W. K. Harris & Glynn Isaac

Department of Anthropology, University of California, Berkeley, California 94720

Information concerning the technology, land-use patterns and activities of early hominids is being recovered from the Upper Member of the Koobi Fora Formation. The term Karari Industry is proposed for a distinctive local series of artefact assemblages that date to the period between 1.2 and 1.6 Myr BP.

THE area east of Lake Turkana (formerly Rudolf) is now well known for the large series of hominid and other fossils that Leakey *et al.* have recovered there[1-8] Researches in the area since 1970 have also yielded an abundance of archaeological traces that relate to the activities and behaviour of early hominids. Two series of archaeological occurrences can be recognised. An older series which occurs in the top of the Lower Member of the Koobi Fora Formation, chiefly in the KBS Tuff complex, has been the subject of preliminary reports[7-9]. The artefacts from these sites can be tentatively termed the KBS Industry A younger, contrasting series has subsequently been discovered in the Upper Member. This is described here for the first time, and we propose that it be designated the Karari Industry.

Provenance and stratigraphy

Sites pertaining to the newly discovered archaeological entity occur in great profusion along a low eroded ridge that has come to be known to our research group as the Karari Escarpment (Figs 1 and 2) and we have used the association with this topographic feature in naming the industry Samples of the industry, however, have also been recovered from the dip slope to the east of the Karari escarpment, and from the Ileret area. The locations of known sites are marked on Figs 1 and 2, but other areas remain to be explored and it is probable that the distribution will eventually prove wider than that shown.

All sites are designated in accordance with the standard African site enumeration system[10]. The letters identify a series of geographic rectangles bounded by lines of latitude and longitude at one quarter degree intervals. Thus FwJi denotes the square 4°15′–30′N and 36°0′–15′E while FxJj refers to the square 4°0′–15′N and 36°15′–30′E. The digits that follow are catalogue numbers that reflect the sequence of registration.

Table 1 summarises the stratigraphic relationships of the sites to each other and to the named units designated by Bowen and Vondra[11] Along the Karari escarpment and on the dip slope to the east, the sites are stratified in fluviatile deposits between the KBS Tuff complex and the Karari Tuff. They are particularly abundant in the strata associated with the Okote Tuff complex (formerly the BBS Tuff complex)[11]. They occur scattered through a cumulative thickness of some 50 m of sediments in the Karari area. In the Ileret area the sites occur in low energy river floodplain

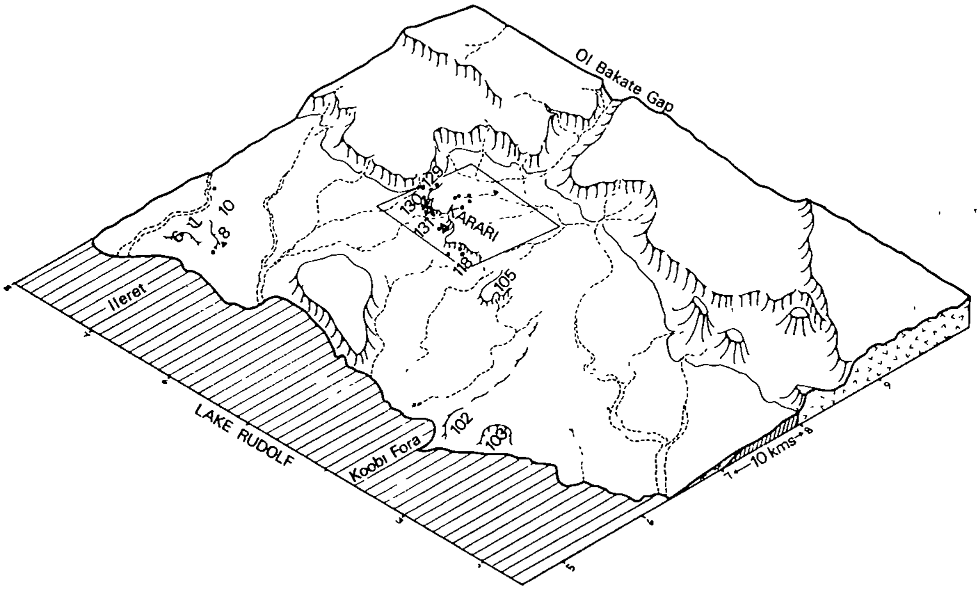

Fig. 1 Isometric block diagram showing the position of the Karari and Ileret sites in relation to present-day physiography. Numbers 1-131 refer to the expedition area numbers; rectangle designates the area shown in Fig. 2.

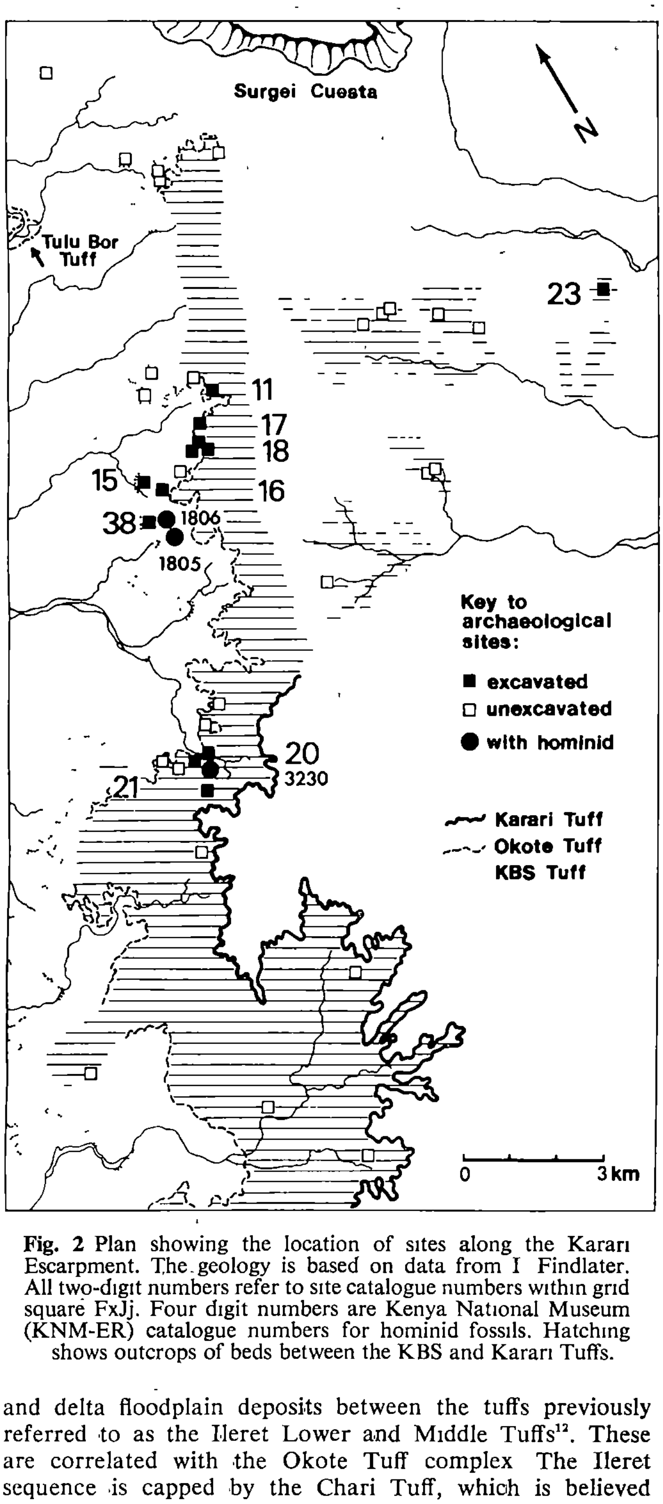

Fig. 2 Plan showing the location of sites along the Karari Escarpment. The geology is based on data from I Findlater. All two-digit numbers refer to site catalogue numbers within grid square FxJj. Four digit numbers are Kenya National Museum (KNM-ER) catalogue numbers for hominid fossils. Hatching shows outcrops of beds between the KBS and Karari Tuffs.

and delta floodplain deposits between the tuffs previously referred to as the Ileret Lower and Middle Tuffs[12]. These are correlated with the Okote Tuff complex The Ileret sequence is capped by the Chari Tuff, which is believed to correlate with the Karari Tuff, and thus the entire series of sites treated in this report can be said to derive from the stratigraphic interval between the KBS Tuff complex and the Chari-Karari Tuffs. Lake margin sediments that correlate with this interval also crop out in the vicinity of the Koobi Fora spit, but archaeological materials have not been recovered from these exposures.

In biostratigraphic terms, the interval from which the samples of the Karari Industry derives coincides largely with Maglio's *Loxodonta africana* zone[13].

Dating evidence

Table 2 shows the series of published potassium–argon determinations by Fitch and Miller that have a direct bearing on estimation of the age of the Karari archaeological occurrence[14]. An upper limit is set by dates of 1.32 ± 0.11 Myr and 1.22 ± 0.01 Myr for the Karari and Chari Tuffs, respectively. These dates are statistically indistinguishable and are believed to represent the same eruptive event. Technically, the lower age limit should be set by the age of the KBS Tuff, for which Fitch and Miller, using the $^{40}Ar/^{39}Ar$ step heating method, obtained a best estimate of 2.61 ± 0.26 Myr (ref. 14). Subsequently, Curtis *et al.* reported that they have made six conventional K–Ar determinations on samples from the KBS Tuff at the foot of the Karari Escarpment in Area 131. These values cluster closely around a mean of 1.8 Myr (ref. 15). The reasons for the discrepancy between the two sets of results are still under review. But, although the KBS Tuff is the marker horizon that forms the lowermost boundary of the stratigraphic interval containing the Karari Industry, most of the sites are contained in the strata at or above the level of the Okote Tuff complex and its equivalent at Ileret. Dates of 1.57 and 1.48 Myr for these tuffs, respectively, clearly provide the best indicators of the lower limits of the time interval in question.

Further chronological evidence has been obtained from palaeomagnetic stratigraphy[16]. The beds yielding the industry show predominantly reversed magnetic polarities and the few apparent normal results which were obtained at Ileret seem very likely to result from remagnetisation during the Brunhes Epoch. Since the Earth's field was reversed in the interval 1.2–1.6 Myr BP, the palaeomagnetic determinations for the Upper Member Beds are consistent with the K–Ar dates.

Biostratigraphic data are also concordant with these age determinations. On the basis of comparisons among various dated East African faunal samples, Maglio gave a best estimate of 1.3 Myr for the *Loxodonta africana* zone at East Rudolf, with the limits of uncertainty set at 1.0–1.6 Myr (ref. 13). More detailed work is being undertaken by J. M. Harris of the Kenya National Museum and his recent work does not suggest any need for major revisions in the biostratigraphic correlation of this part of the sequence, though the nomenclature will be changed (personal communication).

Characteristics of artefact samples

The overall characteristics of the series of artefact samples we have recovered can best be represented by the application of the typological system devised by Leakey[17], though it has been necessary to add one or two categories. Table 2 presents a summary for each excavated assemblage of the percentage incidence of specimens in each artefact category.

Each assemblage comprises two fundamentally distinct classes of specimens. first, there are comparatively thick, massive boulders, cobbles and blocks of stone from which flakes have been removed by percussion, and second, there are relatively thin slivers of stone produced by conchoidal fracture. The first are termed 'cores', in the broadest sense of the term, and the second, 'flakes' and 'flake fragments'. Superimposed on this dichotomy is another important distinction: items which have been purposively shaped to particular patterns are set apart and referred to as 'tools', the word having a restricted technical sense. By contrast, the category 'debitage' contains 'flakes' and 'flake fragments' which have not been secondarily trimmed, plus those 'cores' that are regarded merely as by-products of flake production. This semantic distinction is not meant to imply that items of debitage were never used as implements. There are good reasons for believing that unretouched sharp flakes were functionally as important as the formally defined 'tool' category. Objects that are 'non-tools', in the above sense, but which show damage attributable to use are put in the third category often defined 'utilised', but we prefer the designation 'edge damaged' for this set.

Among early stone industries most of the cores (*sensu lato*) also seem to have been designed as 'tools' and at

Karari Industry sites are shown in bold face and hominid fossil finds in italic. KBS Industry sites are shown thus: FxJj 1 and so on.

Olduvai Gorge, M. D. Leakey found varied evidences of their usage as implements. For this reason in Tables 2 and 3 choppers, discoids, polyhedra, core scrapers and so on are all included as tools, although they undoubtedly also had importance as the source of flakes that were themselves useful. As Table 3 shows, in these assemblages, as in most Pleistocene industries, debitage is numerically the preponderant category with percentage values ranging from 58 to 99%. For the purpose of archaeological taxonomy, however, tools are usually regarded as the most important class.

Most of the artefacts are made of volcanic lava, particularly basalt, but also of feldspathic ignimbrite, rhyolite and a glassy welded tuff. The commonest source seems to have been the cobbles and boulders being transported by the streams that traversed the Karari area. This material was readily available and had good flaking qualities Less than 5% of the artefacts were made of other materials such as chert and quartz.

The most distinctive and abundant tool forms present are core scrapers and light duty scrapers (Fig. 3). Typical core scrapers are made on cobbles or split cobbles with one flat surface used as a striking platform. Commonly, more than one generation of flakes were removed from the dorsal surface to form a steep edge. In many cases, much of the perimeter of the scraper has been trimmed so that the dorsal face developed a keeled or domed configuration.

In contrast, the light duty scrapers are made of flakes or flake and core fragments, and are thin in cross-section compared with core scrapers. In many cases the trimming is regular and well controlled, giving the pieces slightly denticulated or serrated edges.

Other tool forms, such as choppers, protobifaces, dis-

Table 2 Potassium–argon dates for the upper part of the Koobi Fora Formation

Ileret	Karari Escarpment	KBS (Area 105)	Koobi Fora
Chari Tuff 1.22 ± 0.01 Myr (FMA 280, ref 14)	Karari Tuff 1.32 ± 0.10 Myr (FMA 290, ref. 14)		
Lower/Middle Tuff Complex 1.48 ± 0.17 Myr (FMA 278, ref. 14)	Okote Tuff Complex 1 56 ± 0.02 Myr (FMA 266, ref 14)		Koobi Fora Tuff 1.57 ± 0 0 Myr (FMA 270, ref. 14)
KBS Tuff Complex 1.57 Myr (Curtis *et al.*[15])	KBS Tuff Complex 1.82 ± 0 04 Myr (Curtis *et al* [15])	KBS Tuff 2 61 ± 0.26 Myr (Fitch *et al.*[14]) 1.61 Myr (Curtis *et al.*[15])	

coids and polyhedra occur with less frequency. A few bifaces and cleavers have been recovered from surface localities in circumstances that demonstrate conclusively their derivation from Upper Member beds. These tool forms, however, seem to be very rare in the material that is concentrated in occupation sites and have not yet been recovered by excavation.

The unbroken flakes show distinctive morphological features: small restricted platforms and diffuse bulbs of percussion. In particular, at sites associated with stream channels, battered cobbles and large boulder cores are present from which large well struck flakes had been struck. The trimming of the core tools must have also yielded numbers of flakes.

Comparisons and taxonomy

Very few datable artefact assemblages are known from the time span between 1 and 1.5 Myr BP. By far the largest and most detailed body of comparative data is that which derives from Bed II at Olduvai Gorge[17]. M. D. Leakey, who excavated the Olduvai material, recognised two main varieties among the samples that occur above the Lemuta Member: The Acheulian Industry and the Developed Oldowan Industry with the latter being subdivisible into phases A and B. Tables 2 and 3 show percentage frequency data for selected examples of Olduvai assemblages. Comparison of the two sets of data shows that not all the samples from the Upper Member of the Koobi Fora Formation are distinguishable from the Olduvai series; for example, FxJj 38 is not unlike FLKN level 5. But most Karari samples differed markedly, by virtue of the large percentages of core scrapers and other scrapers.

There are other contrasts. Polyhedra and discoids are more numerous at Karari sites but inhibit less battering and blunting of edges than is commonly evident in the Olduvai samples. The Karari assemblages lack spheroids and subspheroids, while these forms are present in relatively large proportions at most of the Bed II sites. The Karari Industry also contains core and cobble fragments with retouch on the ventral face, which could not be accommodated in any of the typological categories proposed by M. D. Leakey. A separate class has been added to the type list to represent these.

Very few awls, burins or picks have been recovered from the Karari sites, whereas at Olduvai these forms occur more frequently, although in small quantities. A variable series of unstandardised trimmed pieces in both the Olduvai and Karari samples have been classified as 'sundry tools'.

Other assemblages from the age range in question should be mentioned briefly. The samples from the Humbu Formation at Peninj include large percentages of bifaces and are therefore unlike the Karari material[18,19]. The tool component of the sample from Sterkfontein Extension site is dominated by choppers, polyhedra and spheroids and is therefore much more like the Developed Oldowan than the Karari Industry[20]. Although the time relationships of the early material from North Africa are not known with certainty, sites such as Ain Hanech, or Sidi Abderhaman Ancien Exploitation level J may be of comparable age[21]. None of these assemblages includes significant numbers of core scrapers of Karari type.

In each comparison it is largely the morphology of the core scrapers that distinguishes the Karari series. The form range of other tool categories such as choppers, polyhedra and discoids, overlaps extensively with that of the equivalent sets in other assemblages. The rare bifaces that derive from the Upper Member are very like those of Olduvai Bed II, Peninj or the Lower Acheulian of North Africa.

It thus emerges that the morphological pattern shown by the assemblages from the Upper Member of the Koobi Fora Formation falls outside the known range of other described, contemporary classificatory sets. In accordance with the procedures proposed by the 1965 Burg Wartenstein Symposium[22], and endorsed by the Sixth Pan-African Congress on Prehistory and the Study of the Quaternary, we propose to designate this distinctive series the Karari Industry.

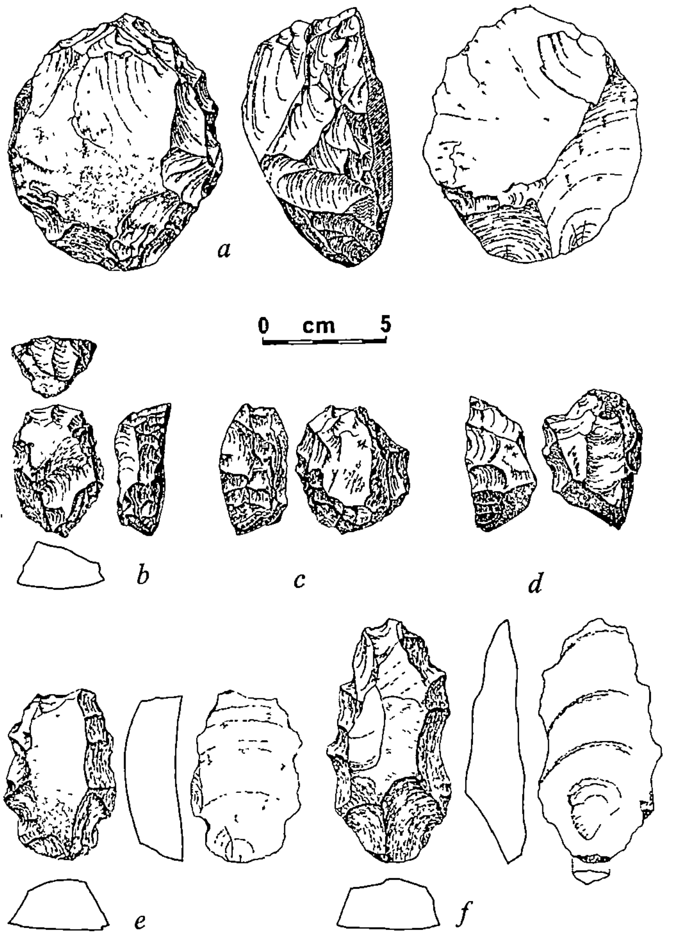

Fig. 3 *a*, Core scraper, FxJj 11; *b*, core scraper, FxJj 20 Main; *c* and *d*, core scrapers, FxJj 20 AB; *e*, core scraper, FxJj 20 IHS; *f*, light-duty scraper on flake, FxJj 18 NS. Made on lava. Drawings by Barbara Isaac.

As a formal definition we offer the following: the Karari Industry is a set of early Pleistocene artefact assemblages that shares broad, generalised features with other near-contemporary industries such as the Developed Oldowan Industry from Bed II at Olduvai, but which also shows distinctive patterns of differences from them. Generalised features held in common include the preponderance of opportunistic flaking technology in which highly organised, fixed patterns of core preparation are rare or lacking. Choppers, polyhedra and discoids are important components of the Karari Industry as in many other generalised industries. Handaxes and cleavers seem to have been a rare but significant part of the total artefact repertoire, as in the case of the Developed Oldowan B. The Karari Industry, however, is distinguishable from all other near-contemporaneous industries by the tendency of its component assemblages to include a conspicuous series of core scrapers. The percentage incidence of these is variable. A few assemblages, that clearly formed part of the material culture system that we are designating as the Karari Industry, show a low or negligible incidence of the key forms, but in most, where the sample is large enough, they are present in proportions well outside the range observed in other contemporary industries. In the Karari Industry even the scrapers that are not specifically core scrapers are distinct from those of most Oldowan assemblages in their tendency to be more massive.

The data for Olduvai Gorge are from ref. 18. Percentages for the tool types relative to the tool subset are rounded to the nearest whole number. Values for samples of less than 20 are shown in parentheses. RCCF, retouched core and cobble fragments.

* The other minor categories for which percentages are not shown are 'modified' and 'edge damaged' (= utilised).

† For the Olduvai analyses the distinction is between heavy duty and light duty scrapers.

If an associated set of excavated artefacts is needed as a type sample of the newly defined industry, we would nominate the archaeological material from the FxJj 18 Site Complex as suitable. (That completes the definition.)

The decision to name this material as a distinguishable industry is based solely on considerations of the morphology of the archaeological materials. We do not necessarily wish to infer the former existence of a 'cultural entity' or an ethnic entity that could be equated with the Industry. We also wish at present to avoid a definite judgement on the formal taxonomic relationships at any level of classification wider than that involved in grouping a set of related assemblages into an Industry. Clearly the material may be related in some way to the contemporaneous Developed Oldowan and Acheulian at Olduvai. It involves elements of both modes 1 and 2 in the schema of Clark[23].

Palaeoecological context and behavioural interpretations

An extensive archaeological survey has been carried out at Ileret and along exposures of the Karari Escarpment to gain some understanding of the early Pleistocene man–land relationships represented in the area. The distribution of sites in relation to the mosaic of former habitats is potentially informative of the ecological relationships of early hominids. We found that they used the riverine floodplains and the alluvial fan deposits near the basin margins. Probably their range also included the valleys and hills of the more elevated surrounding terrain. These data are consistent with the idea that early hominids were mobile, opportunistic hunters and gatherers who used a wide range of resources.

More than 50 sites have been located and of these only two are in deposits laid down near the lake margins at Ileret, while the remainder are in varied alluvial deposits that formed 15–25 km inland from the shoreline. Of the 17 excavated sites nine are in direct association with the deposits of former stream channels while six are contained in the silty deposits of the broad floodplains that lay in between the stream channels. In addition to the excavated sites, we have located a further 40 archaeological occurrences through their surface traces, and these are potential sites for further investigation.

Several features emerge from an analysis of the pattern of distribution of the archaeological sites. Traces of past activities are found close to water sources, such as stream or river channels. This association has been observed elsewhere and may tentatively be explained by the fact that tree- and bush-lined stream channels would have provided shade and shelter as well as sources of nuts and berries. Ready access to raw material may have been another factor; in some cases, sites were located on gravel bars in stream channels in close proximity to patches of basalt cobbles and boulders.

Fossil bone is rather rare and poorly preserved in the deposits containing the Karari Industry. But sealed 'living floors' that contain stone artefacts plus small quantities of bone fragments, generally in a highly comminuted state, do occur chiefly in floodplain contexts Detailed study of bone samples is in progress.

Hominid remains occur interstratified with archaeological sites of the Karari Industry A hominid mandible, KNM-ER 3230 (*Australopithecus* cf. *boisei*) was recovered by excavation 10–15 cm stratigraphically above the artefact-bearing horizon at FxJj 20 E[25] In area 130, KNM-ER 1805 (*Homo* sp. ?) and KNM-ER 1806 (*Australopithecus* cf *boisei*) were recovered 40 m from FxJj 38 on the same stratigraphic horizon within channel deposits[6] A wealth of hominid fossils, including specimens assigned to *Australopithecus* (cf. *boisei*) and *Homo* have been recovered in beds of the Ileret Member[1–6].

The discovery of the Karari sites has added significantly to knowledge of artefacts that are more than 1 Myr old. Well dated, excavated samples were previously available only from Olduvai[17], Peninj[18,19], the Shungura Formation (Omo)[24], the Lower Member of the Koobi Fora Formation[8,9] and perhaps Ain Hanech in Algeria[21] and Sterkfontein in the Transvaal[20]. Variety among this series is considerable and we suspect that as the sample is enlarged, an even greater range of differences will be discovered between sets of sites characteristic of the various regions in which evidence is preserved. Many factors could have interacted to cause variety; for example, differences in the characteristics of available stone; differences in particular, local needs for certain implements and perhaps fluctuating regional differentiation in habits. To distinguish the relative importance of these and other factors, we will need a far larger sample of assemblages that have been drawn from a varied spectrum of contexts, in each of several separate sedimentary basins. Our naming of the Karari Industry as an entity is not intended to prejudice the outcome of this kind of research; it simply reflects the fact that the material from the Upper Member of the Koobi Fora Formation is distinctive and a clear unambiguous label is needed for it.

We thank Richard Leakey, Kamoya Kimeu and the National Museums of Kenya for encouragement and support. The archaeological work was financed by grants from the NSF and the project also in part by grants from the National Geographic Society and the NERC. We are also grateful for help from P. Abel, A. K. Relationship between receptor and mammary tumour virus production after stimulation by glucocorticoid

G. Shyamala* & C. Dickson†

Department of Zoology and Cancer Research Laboratory, University of California, Berkeley, California 94720

A short exposure of primary cultures of mouse mammary tumour cells to glucocorticoids results in at least a threefold stimulation of mammary tumour virus (MTV) production. Specific interaction of glucocorticoids with the cytoplasmic and nuclear receptors can also be demonstrated. The biological potency of various steroids to stimulate MTV is related directly to the retention of the steroid–receptor complex in the nuclei. Progesterone has a high affinity for the cytoplasmic receptor, is not retained by the nuclei and does not stimulate or block the basal level of MTV production. It is, however, quite effective in abolishing the glucocorticoid-mediated stimulation of MTV and thus behaves as an antagonist of glucocorticoid.

CULTURES of cells and cell lines derived from primary mouse mammary tumours can be stimulated by glucocorticoids to produce increased quantities of mammary tumour virus (MTV) particles[1–7]. The biological activity of glucocorticoid hormones is believed to be mediated through a specific interaction of the steroid with the steroid hormone receptors[8]. The presence of cytoplasmic and nuclear glucocorticoid hormone receptors in mouse mammary tumour cells have been demonstrated[9–11]. A positive correlation has been reported between the binding of a steroid to the cytoplasmic glucocorticoid receptor and its biological potency in inducing MTV (ref. 11). These studies, however, failed to explain the role of progesterone in MTV synthesis because, in spite of its high affinity to the cytoplasmic receptor, it failed to stimulate MTV synthesis. Based on the observations that progesterone is an effective competitor for the cytoplasmic glucocorticoid receptor but cannot compete effectively with the glucocorticoid receptor-binding sites in the nuclei, we have postulated that progesterone is an antagonist of glucocorticoid action in mouse mammary tumour cells[10]. We now report the presence of cytoplasmic and nuclear glucocorticoid hormone receptors in cultured primary mouse mammary tumour cells; the acceleration of MTV production mediated by a short exposure to glucocorticoids as opposed to the continuous exposure to steroids used in previous studies, and an antagonistic action of progesterone on glucocorticoid-mediated stimulation of MTV.

†Present Address. Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, UK.

Mouse mammary tumour cell cultures were prepared from spontaneous mammary tumours arising in BALB/cfC3HCrgl and C3H/Crgl mice as described by McGrath[1]. There was no significant difference between BALB/cfC3H and C3H cells with respect to either virus production or the effect of hormones on MTV synthesis. Dissociated cells were plated in 60-mm or 100-mm Petri dishes (Falcon) at a seeding density of 5×10^5 cells per cm^2 in Dulbecco's modified Eagle's medium containing 15% foetal calf serum (Gibco), penicillin ($100\ U\ ml^{-1}$), streptomycin sulphate ($100\ \mu g\ ml^{-1}$) and bovine insulin ($10\ \mu g\ ml^{-1}$, Sigma). Cell cultures to be pulsed with steroids were changed to serum-free medium 24 h before the pulse, washed twice after the pulse and incubated for a further 24 h in serum-free medium. The resulting culture fluids were assayed for DNA polymerase activity.

For glucocorticoid receptor assays, all preparative procedures were carried out at 0–4 °C. The cells were homogenised in known volumes of TESH buffer (0.01 M Tris, 0.0015 M EDTA, 0.012 M thioglycerol, *p*H 7.4). The homogenate was centrifuged at 800*g* for 10 min. The supernatant was designated the cytoplasmic extract. The nuclear pellet was resuspended and centrifuged once in phosphate-buffered saline and once in phosphate-buffered saline containing 0.25 M sucrose. The pellet was then extracted with TESH–KCl buffer (TESH buffer containing 0.4 M KCl, *p*H 7.4) and centrifuged and the supernatant extract was designated the nuclear extract. The binding reaction was performed at 0–4 °C by incubation of aliquots of cytoplasmic extracts with known concentrations of the radioactive steroid, either alone or in the presence of competing non-radioactive steroid. After incubation for 120 min. (unless otherwise stated), binding in the cytoplasmic extract was assayed using a Sephadex G-25 filtration technique previously described[9] or by the DEAE–filter assay of Santi *et al.*[12]. Binding capacity determined by the two procedures did not differ significantly. The total radioactivity present in washed nuclear pellets was extracted with 3 ml of ethanol and counted with 10 ml of scintillation fluid. Bound and unbound labelled steroid in nuclear extracts was separated by gel filtration on Sephadex G-25 columns using TESH–KCl buffer.

The DNA polymerase activity present in the tissue culture fluid from tumour cell cultures was processed as previously described[2,13]. Assays were performed in reaction mixtures containing 50 mM Tris-HCl buffer, *p*H 8.3, 40 mM KCl, 10 mM $MgCl_2$, 0.04 A_{260} units of poly(rC)·oligo$(dG)_{12-18}$ (P. L. Biochemicals) and 5 μCi of ^{3}H-deoxyguanine triphosphate ($9.3\ Ci\ mmol^{-1}$) at 37 °C for 40 min. Assays were also performed using reaction mixtures containing Tris-HCl buffer, *p*H 7.4 and Mn^{2+} (0.5 mM).

To estimate DNA content, cell cultures were washed twice with Hanks balanced salts solution, scraped from the dish and precipitated with an equal volume of 10% perchloric acid (PCA) at 4 °C. After 30 min the precipitates were collecetd by centrifugation at 1,600*g* for 10 min and washed twice with cold 5% PCA and twice with 70% ethyl alcohol : 30% diethyl ether, and the pellet was allowed to dry. The pellet was dissolved in 1 N NaOH and left at 20 °C overnight, neutralised with HCl and reprecipitated with an equal volume of 10% PCA at 4 °C. The precipitate was washed twice with 5% PCA and hydrolysed in 5% PCA at 85–90 °C for 30 min. After hydrolysis the samples were mixed, centrifuged at 1,600*g* for 10 min and aliquots were assayed for deoxyribose content using the method described by Burton[14]. Hydrolysed calf thymus DNA was used as a standard.

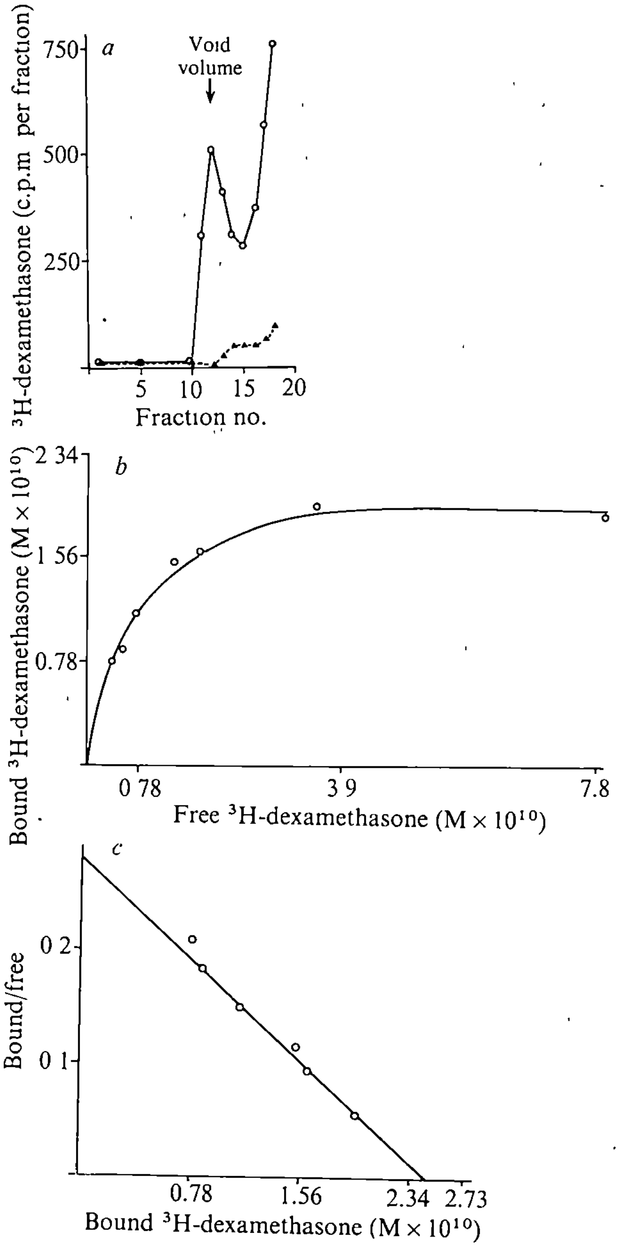

Fig. 1 (*a*), Binding of ^{3}H-dexamethasone in the cytoplasm of cultured mammary tumour cells. Samples (0.4 ml) of cytoplasm were incubated with 1.7×10^{-9} M of ^{3}H-dexamethasone (○) or with 1.7×10^{-9} M of ^{3}H-dexamethasone and 10^{-7} M unlabelled dexamethasone (▲) at 4 °C for 2 h. Bound radioactivity in each incubation was assayed on Sephadex G-25 columns (*b*), Kinetics of specific cytoplasmic binding of ^{3}H-dexamethasone. Samples of cytoplasmic extracts were incubated with various concentrations of ^{3}H-dexamethasone with or without 100-fold excess of unlabelled dexamethasone for 2 h at 0–4 °C. The data, represented as molar bound steroid in the total incubation, are plotted as a function of free-steroid concentration at equilibrium. The free steroid was determined by subtracting the bound steroid from the total steroid present in the incubation mixture. (*c*), Scatchard plot of the binding data from (*b*).

Strong interactions of ^{3}H-dexamethasone with the macromolecules of the cytoplasmic extract of mammary tumour cells in culture were revealed by gel filtration analyses (Fig. 1*a*). Specific binding was eliminated when the extract was incubated with labelled dexamethasone in the presence of an excess of unlabelled dexamethasone. This indicates that there was only a limited number of binding sites for dexamethasone. The amount of specifically bound ^{3}H-dexamethasone in the cytoplasmic extracts of cultured cells as a function of the free steroid concentration is shown in Fig. 1*b* Saturation of the binding sites was reached when the free steroid concentration was about 4×10^{-10} M. The specific binding data were also plotted by the Scatchard[15] technique (Fig. 1*c*) and yielded a single straight line, indicating that only a single class of binding site was present The equilibrium dissociation constant of the binding of the steroid to the receptor was estimated to be $8\,8\times10^{-10}$ M. The average dissociation constant as determined from four separate experiments using various concentrations of cytoplasmic extract was estimated to be 1.6×10^{-9} M. On the basis of the Scatchard plot, it can be assumed that 1 mol of steroid is bound to 1 mol of receptor. Thus, assuming 6.6×10^{-6} μg of DNA per cell nucleus, based on the average DNA content of the tumour cells in culture (0.015 μg DNA per 10^{7} cells), there are about 1,800 sites per cell. The average number of binding sites per cell as determined from four separate experiments was estimated to be approximately 1,400. Binding activity was destroyed by incubating cytoplasmic extracts with trypsin (500 μg ml^{-1}) or Pronase (100 μg ml^{-1}). Similar treatment, but with DNase (bovine pancreas 100 μg ml^{-1}) and RNase (100 μg ml^{-1}), had no effect on the binding. Therefore the cytoplasmic receptors seem to be proteins. Various non-radioactive steroids were tested for their ability to compete with ^{3}H-dexamethasone for the receptor binding (Fig. 2). The order of affinity of various steroids to the cytoplasmic receptor was dexamethasone > deoxycorticosterone > corticosterone > progesterone > hydrocortisone.

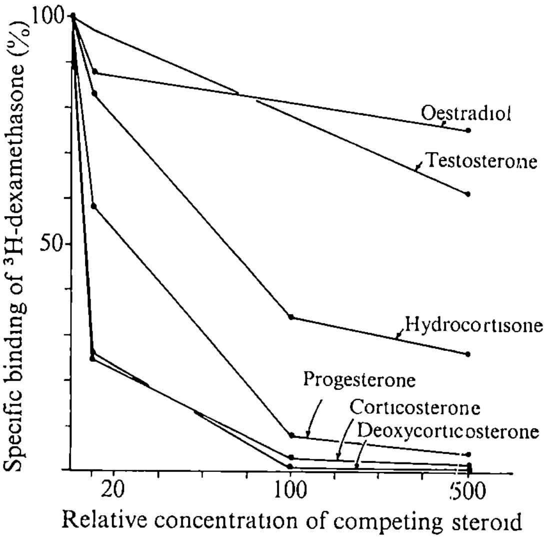

Fig. 2 Effect of various unlabelled steroids on binding of ^{3}H-dexamethasone to cytoplasmic extracts of mammary tumour cells in culture. Aliquots of cytoplasmic extracts were incubated with 10^{-9} M ^{3}H-dexamethasone alone or with various concentrations of non-radioactive steroids at 4 °C for 2 h Binding was measured by DEAE-filter assays as described in the text. Non-specific binding has been subtracted.

It has been proposed that the effect of glucocorticoids in target tissues results from steroid-mediated interaction of the receptor with the genome[16]. To examine this phenomenon in mammary tumour cell cultures, we made parallel studies on the nuclear localisation of dexamethasone and its stimulation of MTV. The data on the specific nuclear binding of steroids, and the subsequent stimulation of MTV in primary cultures of mammary tumour cells are shown in Fig. 3. The specific nuclear binding of dexamethasone was nearly complete by 30 min (Fig. 3*a*); as with other steroid receptor systems, nuclear binding was derived from the receptor in the cytoplasm because the total receptor binding in the cells remained constant throughout the experiment. The specific binding of ^{3}H-dexamethasone in the nuclei reached saturation with 10^{-8} M ^{3}H-dexamethasone in the incubation medium (Fig. 3*b*). As with fresh tumour slices[9,10], 10–20 times more than a saturating amount of steroid with respect to cytoplasmic receptor was required to achieve nuclear saturation. About 90% of the nuclear bound radioactivity could be solubilised and the radioactivity in the nuclear extract was bound to a macromolecule (Fig. 3*c*). Pulsing the cells with dexamethasone for 30 min was also sufficient to evoke a subsequent near maximal stimulation of MTV (Fig. 3*d*). The effect on MTV was most pronounced in the cultures assayed between 12 and 24 h after exposure to the steroid as opposed to earlier (0–12 h) or later (24–36 h) (data not shown). The dose–response curve for dexamethasone in stimulating MTV is presented in Fig. 3*e*, and Fig. 3*f* represents a plot of the relative potency of a given steroid to stimulate MTV and the amount of that steroid specifically bound in the nuclei.

Since mouse cells contain endogenous type C oncornaviruses which after induction may or may not be stimulated by glucocorticoids[7,17–19], the cultures were also monitored for the presence of type C virus, using the divalent cation preference of the DNA polymerase reaction. The MTV–DNA polymerase will utilise the template-primer poly(rC)·oligo(dG)$_{12-18}$ 70 times more efficiently with Mg^{2+} as the divalent cation than with Mn^{2+}, whereas murine type C viruses (Moloney MSV/MuLV) show a greater efficiency with manganese (our unpublished observations)[7,20,21,22]. Furthermore the DNA polymerase activity in the tissue culture fluid from mammary tumour cells was shown to be associated with the MTV virion by biophysical, morphological and immunological criteria[2]. In all the experiments described, parallel assays had been performed to determine the presence of type C viruses and no evidence was found for significant type C virus production. Furthermore, in some experiments, culture virus was also analysed for its viral polypeptide composition and in all cases only the MTV-specific polypeptide components were present (data not shown). Thus we are reasonably assured that the viral polymerase activities reported here represent the activity due to MTV and also reflect the virus production.

Previous studies from this laboratory[10] have demonstrated that the binding of progesterone to the glucocorticoid receptor of mouse mammary tumours does not lead to the translocation of the receptor to the nucleus and this was also true with tumour cells in culture (data not shown). As shown in Fig 3, the nuclear-bound steroid is closely related to the stimulation of MTV, and therefore as suggested previously[10], it is possible that progesterone acts as an antagonist to the glucocorticoid-mediated stimulation of MTV. The results of the following experiments demonstrate that this may indeed be true. Exposure of cell cultures to progesterone alone for 30 min did not stimulate MTV but neither did it block the basal level of MTV production (Table 1). This agrees with earlier observations made with progesterone on long term cultures of murine mammary tumour cells[2,7]. If cells were exposed to dexamethasone in the presence of an excess of progesterone, however, there was a reduction in the stimulation of MTV due to dexamethasone (Table 1). The average of three experiments on primary culture of tumour cells indicates that when a 100-fold excess of progesterone is added with dexamethasone, there is a 70% inhibition of the dexamethasone-mediated

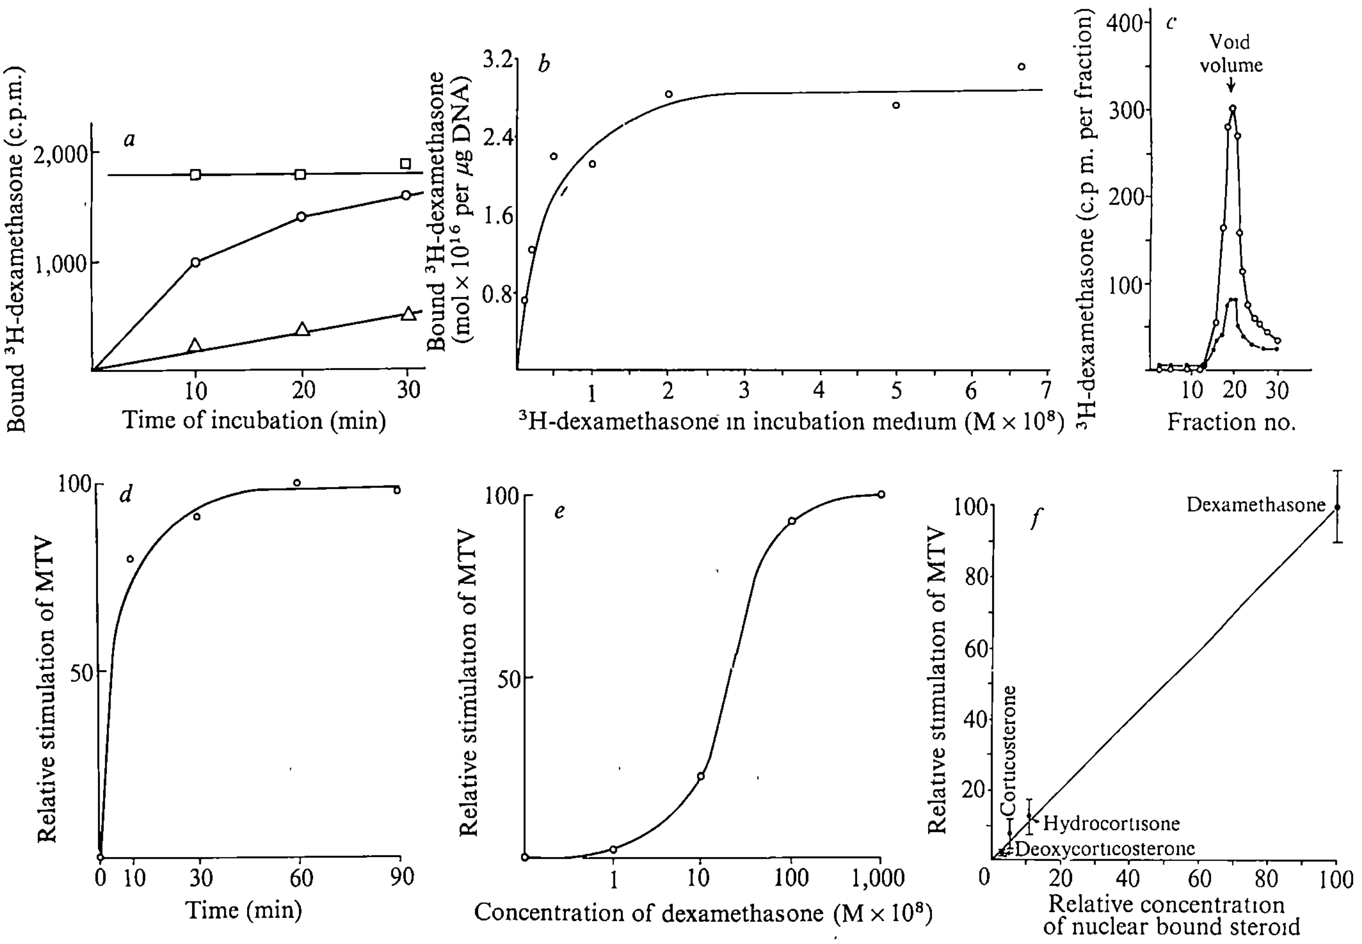

Fig. 3 Nuclear binding of ^{3}H-dexamethasone and its stimulation of MTV. In (*a*)–(*e*), to estimate binding to receptor, the cells were incubated at 37 °C with specific concentrations of ^{3}H-dexamethasone for specified times. Parallel sets of incubations were done with 100-fold excess of non-radioactive dexamethasone to determine nonspecific binding. At the end of the incubations, cell fractions were prepared and assayed for binding. The rate of MTV synthesis was estimated by assaying for DNA polymerase activity in the tissue culture fluid from duplicate cultures of tumour cells 24 h after exposure to steroid. (*a*), Cells were incubated with 10^{-8} M ^{3}H-dexamethasone with or without 100-fold excess of unlabelled dexamethasone. ○, Nuclear binding; □, specific nuclear and cytoplasmic binding; △, nonspecific nuclear binding. (*b*), Cells were incubated with various concentrations of ^{3}H-dexamethasone for 30 min. (*c*), Gel filtration on Sephadex G-25 columns of nuclear extracts of tumour cells in culture labelled with ^{3}H-dexamethasone only (○) or also with 100-fold excess of unlabelled dexamethasone (●). (*d*), Tumour cells were treated with dexamethasone for the times indicated, and culture fluid was assayed 24 h after exposure to steroid. (*e*), Cells were exposed to various concentrations of dexamethasone for 30 min and culture fluids were assayed after 24 h for DNA polymerase activity as indicated in the text. (*f*), Plot of the relative concentration of nuclear receptor-bound steroid and its relative stimulation of MTV. To estimate stimulation of MTV, cells were pulsed with 10^{-6} M of various steroids for 30 min and the tissue culture fluid was assayed 24 h later for viral DNA polymerase activity. To estimate nuclear receptor binding, the cells were treated with 10^{-8} M of various labelled steroids for 30 min, at the end of which binding assays were performed. Parallel cultures were treated also with 10^{-6} M unlabelled dexamethasone. Nonspecific binding was subtracted. The data are therefore due to the specific binding of the labelled steroid to sites specific for glucocorticoid receptor only. In each case the data were calculated as pmol nuclear-bound steroid per mg DNA. The data thus obtained for MTV and nuclear binding with each steroid is expressed as relative to that obtained with dexamethasone. The average stimulation of MTV due to dexamethasone was 2.5 times the basal level. The results are the average of six separate determinations ± s.d.

stimulation of MTV. This supports the notion that progesterone can antagonise the glucocorticoid-mediated stimulation of MTV. Table 1 also shows that to observe a significant antagonistic effect of progesterone on MTV stimulation, the levels of progesterone must be at least 100 times in excess of that of added dexamethasone. This is necessary since the affinity of progesterone to the glucocorticoid receptor is less than that of dexamethasone and hence binding of progesterone to receptor in levels equivalent to dexamethasone occurs only at higher concentrations of progesterone. Treatment of cells for short times with concentrations of progesterone as reported here do not result in any toxicity. This was ascertained by measuring the overall incorporation of labelled amino acids into total cell protein by the tumour cells at the time when the culture fluids were assayed for DNA polymerase activity (data not shown).

The ability of various steroids to stimulate MTV in cultured murine mammary tumour cells has been reported[1-7] and our studies confirm this for primary cultures of mammary tumour cells, and demonstrate that a 30-min exposure to steroids is sufficient to elicit the response at 24 h. Our studies show that cytoplasmic and nuclear glucocorticoid hormone receptors are present in tumour cells in primary culture and, as with other steroid hormone receptors, binding of the steroid to the cytoplasmic receptor is an initial event responsible for the subsequent steroid binding to the nuclei. Also, all steroids that bind to the cytoplasmic receptor of the mammary tumours are not retained by the nucleus, and progesterone falls into this category. This interaction of progesterone with the glucocorticoid receptor binding to nuclei has been described in detail[10]. In the studies reported here we have also demonstrated a direct relationship between the kinetics of the nuclear binding of a steroid and its subsequent stimulation of MTV. In addition, we have shown a quantitative correlation between the retention of the steroid–receptor complex in the nuclei as measured 30 min after exposure to steroid and its ability to stimulate MTV. Therefore, even though progesterone has a high affinity for the cytoplasmic receptor, its failure to remain bound to the receptor in the nucleus can lead to its inability to stimulate MTV. Similarly when used at appropriate concentrations with dexamethasone, it can block the stimulation of MTV by competing with dexamethasone for the cytoplasmic receptor sites and preventing its retention in the nucleus. Thus the data reported here are consistent with the role proposed for progesterone as an antagonist of glucocorticoid action in mammary tumours[10] and in hepatoma cells[23].

Table 1 Progesterone antagonism of dexamethasone-stimulated MTV production

Steroid treatment	Relative stimulation of MTV production ± s.d.
Dexamethasone (10^{-6}M)	$100 \pm 8.9\%$ $n = 6$
Dexamethasone (10^{-6}M) + progesterone (10^{-4}M)	$31.2 \pm 5.6\%$ $n = 6$
Dexamethasone (10^{-6}M) + progesterone (10^{-5}M)	$89.8 \pm 15\%$ $n = 4$
Progesterone (10^{-4}M)	$3.25 \pm 5.2\%$ $n = 4$
Progesterone (10^{-6}M)	$2.75 \pm 2.5\%$ $n = 4$

The results are expressed as % of the dexamethasone-stimulated DNA polymerase activity above the basal level. Cell cultures were pulsed for 30 min with the steroid combinations and the culture fluids were collected 24 h later and assayed for enzyme activity. The average incorporation of the Mg^{2+}-stimulated DNA polymerase activity at 100% was 25,400 c.p.m.

Based on the observed relationship between the retention of the steroid–receptor complex in the nuclei and the subsequent stimulation of MTV, some aspects of the steroid-mediated MTV synthesis can be explained. (1) Although a single, 30-min pulse with steroid is sufficient to translocate the receptor from the cytoplasm to the nucleus and to stimulate the subsequent MTV synthesis nearly threefold, when measured 24 h later, continuous exposure of the cells to the steroid is necessary to maintain the full level of MTV synthesis. This may be because it is necessary to retain in the nuclei optimal levels of steroid–receptor complexes for periods longer than 30 min. But when the steroid is removed from the medium at the end of the pulse, the equilibrium of the subcellular distribution of the steroid–receptor complex can be affected, causing some dissociation of the steroid from the complex in the nuclei. Since a quantitative relationship seems to exist between nuclear binding and MTV synthesis, this can lead to a decreased level of MTV synthesis. In this context it is important to mention that during the 24 h after the steroid pulse and washes, about 10^{-10} M steroid is released from the cells into the incubation medium. In separate experiments where the cells were exposed continuously to 10^{-10} M steroid, at the end of 24 h there was no detectable increase in the viral polymerase activity (data not shown). Thus the observed stimulation of MTV polymerase activity must result from the steroid–receptor complex formed during the pulse and not from the continuous presence of the low level of residual steroid in the medium. (2) Our dose–response curve for dexamethasone-mediated stimulation of MTV indicates that to obtain maximal stimulation, 10^{-6} M dexamethasone is needed while 10^{-8} M dexamethasone seems to be sufficient to saturate most of the receptor sites. It is important to remember, however, that the cells were pulsed with the steroid only for 30 min while the response was measured 24 h later. Thus, it is possible that with 10^{-6} M dexamethasone, there is a near maximal saturation of binding sites and a relatively smaller decrease in the dissociation of the steroid–receptor complex from the nuclei on withdrawal of the steroid at 30 min. This increase in the amount of steroid retained by the nuclei after withdrawal of 10^{-6} M dexamethasone as opposed to 10^{-8} M dexamethasone may be just enough to maintain maximal synthesis of MTV. This may be the reason why, with 10^{-5} M dexamethasone, there is no further increase in MTV synthesis. It is also likely, however, that the dose–response relationships of steroid binding and steroid-mediated MTV synthesis do not fit, and elucidation of this problem must await further studies. (3) Our data show that while deoxycorticosterone has at least as high an affinity as hydrocortisone for the cytoplasmic receptor, it is able to stimulate MTV only suboptimally. As reported earlier[10], even with saturation of all the receptor sites in the cytoplasm with deoxycorticosterone, there is only partial translocation, or retention, of the receptor to the nuclei and this may explain why this steroid is only suboptimally active, for even at high concentrations it cannot lead to maximal stimulation of MTV[2].

The mechanism by which steroids are believed to influence gene expression in target cells involves the binding of the steroid to the cytoplasmic receptor and its subsequent interaction with DNA and chromatin, the net result of which leads to the expression of the phenotypic effect. The data on the glucocorticoid receptor and MTV synthesis obtained with various steroids seem to fit this model. As reported here and elsewhere[10], specific binding of glucocorticoids to cytoplasmic and nuclear components occurs in mouse mammary tumours. As shown here, the interaction of the receptor with the nuclear components seems to be crucially related to MTV synthesis. The accumulation of MTV-specific RNA seems to be a primary response to the steroid[24] and reaches maximum at 6 h and finally as shown here, an effect on MTV synthesis can be demonstrated at 24 h. In this respect, the glucocorticoid-mediated stimulation of MTV is very similar to some of the most carefully studied examples of enzyme induction by steroids[25–27].

Finally, a comment is needed about the nature of glucocorticoid-mediated synthesis of MTV. All data reported so far indicate that the steroid-mediated phenomenon is an amplification of the MTV synthesising apparatus rather than a true induction. This argument is based on the fact that the cells in culture synthesise MTV even in the absence of added steroid and steroids are required only for maximal production. Furthermore, progesterone does not inhibit the basal level of MTV but only that which is mediated by the glucocorticoid. Our studies, however, cannot provide any information with respect to particular sequences involved in the cell–virus interaction which are amplified by the hormonal control. Further investigations are also necessary to see if the primary site of hormone action lies in the host cell or the integrated virus in the host cell.

We thank Dr S. Nandi for support, E. Reid for illustrations and J. Underhill for photography. This investigation was supported by a grant from the NCI.

4S *oop* RNA is a leader sequence for the immunity-establishment transcription in coliphage λ

A. Honigman, S.-L. Hu, R. Chase & W. Szybalski

McArdle Laboratory for Cancer Research, University of Wisconsin, Madison, Wisconsin 53706

oop *RNA, which is initiated at the* p_o *promoter and is 81 nucleotides long, can function as a leader sequence for the λ immunity establishment transcription, previously believed to originate at a special promoter* p_{re} *located in the* y *region. Thus,* oop *RNA seems to have a dual role, either favouring the lytic cycle as a primer for the initiation of λ DNA replication, or leading to the establishment of lysogeny when elongated into the* imm *transcript, which directs synthesis of the repressor.*

To establish and maintain the prophage state, phage λ directs synthesis of the repressor protein, the product of gene *c*I (ref. 1). There are two known modes of repressor synthesis: (1) In the establishment mode, observed early after λ infection, the *c*I transcription is believed to originate at the p_{re} promoter, hypothetically defined by the *c*Y mutations located in segment *y* just to the right of gene *cro* (Fig. 1), and is positively regulated by genes *c*II and *c*III (refs 2–5). (2) In the maintenance mode, characteristic of the established prophage, the *c*I transcription originates at the p_{rm} promoter (originally designated p_c promoter[6]) just to the left of gene *cro* (Fig. 1) and is both positively and negatively controlled by the *c*I product[2,3,7]. Both the maintenance and establishment modes of the *c*I transcription are under the negative control of gene *cro* (refs 1–6).

A small RNA species designated *oop* RNA (ref. 8) is synthesised a short distance upstream from the hypothetical location of the p_{re} promoter. Synthesis of *oop* RNA, which is believed to serve as primer for the initiation of λ DNA synthesis, depends on several phage and host replication functions[9]. Since establishment of lysogeny also depends on some replication functions[2,3,10] and because of the close proximity between the hypothetical location of p_{re} and the site of *oop* RNA synthesis, we sought to establish some relationship between these two entities. Moreover, the isolation and mapping of the *sar* mutations, which affect λ DNA replication but stimulate repressor synthesis overcoming the *c*Y defects, suggested that the establishment mode of repressor transcription might originate at the promoter, designated *pro*, between genes *c*II and *O* (ref. 10).

Specifically, we postulated that *oop* RNA, in addition to serving as the primer for DNA replication, can also have the role of a leader sequence that can be extended into the *imm* region by some anti-termination function, most likely depending on the *c*II and *c*III products. This would imply that the p_{re} promoter, as defined by the *c*Y mutations[2], either does not exist or has only a minor role, whereas the Pre function—that is, promotion of the establishment mode of *c*I transcription, is really carried out by the p_o promoter of the *oop* RNA (ref. 8). As will be discussed later, the *c*42 and similar *cis*-dominant mutations in the *y* segment, which were thought to define th

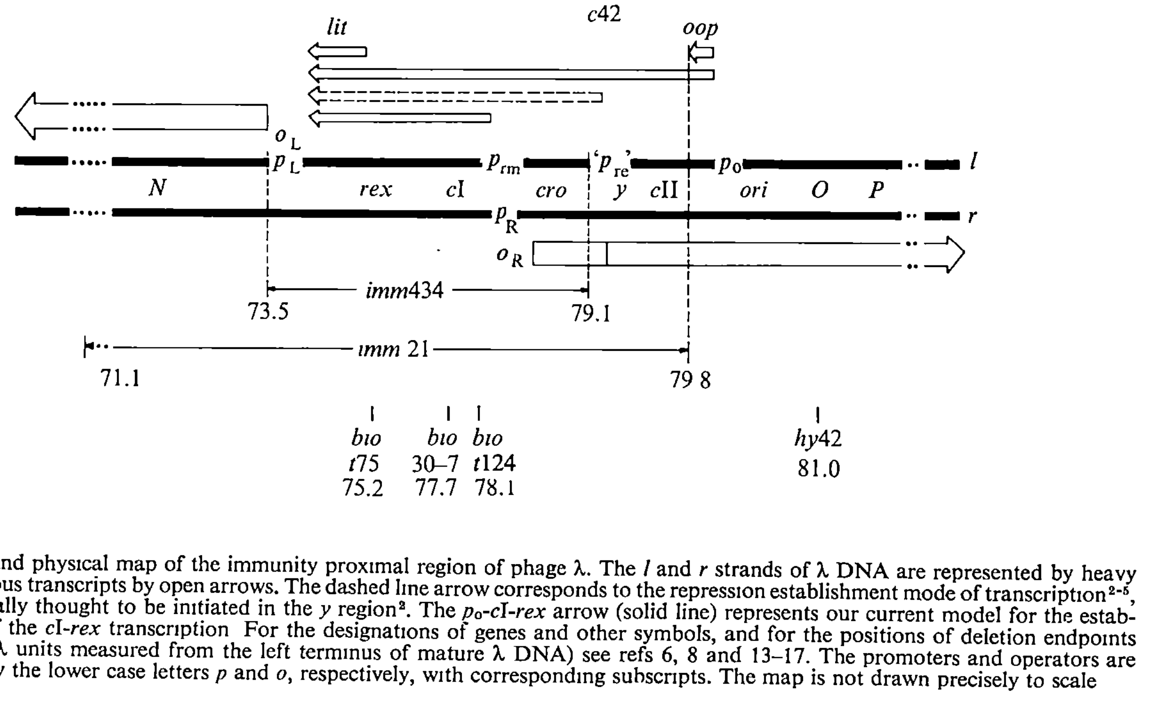

Fig. 1 Genetic and physical map of the immunity proximal region of phage λ. The *l* and *r* strands of λ DNA are represented by heavy lines and the various transcripts by open arrows. The dashed line arrow corresponds to the repression establishment mode of transcription[2-5], which was originally thought to be initiated in the *y* region[2]. The p_o-*c*I-*rex* arrow (solid line) represents our current model for the establishment mode of the *c*I-*rex* transcription. For the designations of genes and other symbols, and for the positions of deletion endpoints (expressed in % λ units measured from the left terminus of mature λ DNA) see refs 6, 8 and 13–17. The promoters and operators are represented by the lower case letters *p* and *o*, respectively, with corresponding subscripts. The map is not drawn precisely to scale

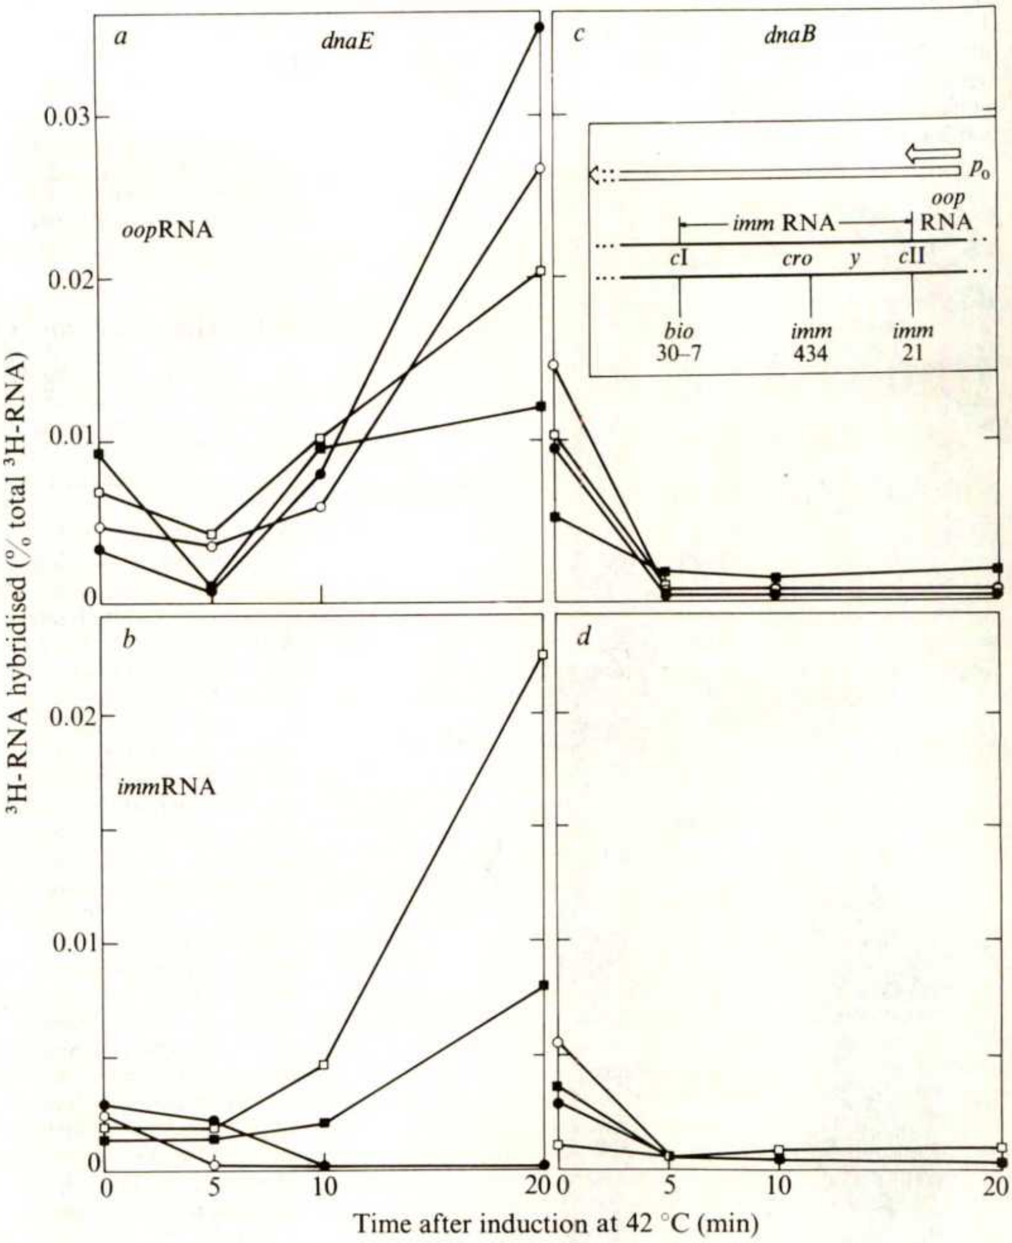

Fig. 2 Leftward transcription of the immunity and *oop* regions after prophage induction. The RNA was labelled for 1 min with ^{3}H-uridine either at 30 °C (zero time) or at the indicated times after induction at 42 °C. The extracted ^{3}H-RNA was first prehybridised to *l* strands of λ*bio*30-7 DNA (see Fig. 1 and inset in *c*), eluted, and then analytically hybridised with *l* strands of φ80λimmλ (hy5)[18] and its derivatives[8], φ80λimm434 and φ80λ*imm*21 (for methods see refs 8, 11). The *oop* transcription (panels *a* and *c*) is calculated as percentage total ^{3}H-RNA input that hybridises to Φ80λ*imm*21. The *imm* transcription (*b* and *d*) is similarly calculated as that ^{3}H-RNA which hybridises to φ80λ*imm*λ minus that to φ80λ *imm*21. Data for the *dnaE*ts (JG55 = E486) and *dnaB*ts (JG28 = Hfr H165/70) lysogens[9,19] are shown in *a*,*b* and *c*,*d*, respectively. The prophages were λ*c*I857 (○), λ*c*I857*cro*27, (□), λ*c*I857 *c*II68 (●) and λ*c*I857*cro*27*c*II68 (■), (see refs 2–4).

p_{re} promoter[1-3], might actually correspond to either transcriptional blocks or one of the sites of the anti-terminating effects of the products of genes *c*II and *c*III.

To prove that the p_o promoter can carry out the Pre function, two experimental approaches were used: one to explore the correlation between the *oop* and *c*I transcriptions, and the other to isolate and characterise the elongated *oop*-*c*I transcript.

Correlation between the establishment mode of *c*I transcription and synthesis of *oop* RNA

The ^{3}H-labelled, leftward-transcribed RNA was assayed by two-step analytical hybridisation[11] within the interval *c*I-*cro*-*y*-*c*II (establishment mode with exclusion of the complications due to the *lit* RNA; ref. 8) and in the *oop* region (see Figs 1 and 2). The experimental design included blockage of λ DNA replication so as to keep the gene dosage constant, inactivation of λ gene *cro* so as to eliminate the shifting expression of its various repressing functions, and thermal inactivation of the *c*Its product to induce prophage, and to minimise the maintenance mode of *c*I transcription and both the positive and negative effects of the repressor[2,3,7]. Because synthesis of *oop* RNA is known to depend on the λ replication functions *ori*, *O* and *P* and the host replication genes *dnaB* and *dnaG*, but not on *dnaE* (ref. 9), the *dnaE*$^-$ host mutation was used to block λ DNA synthesis (Fig. 2*a* and *b*). As controls, *dnaB*$^-$ hosts (Fig. 2*c* and *d*) and P^- λ mutants were included. In other words, the kinetics of the leftward *imm* and *oop* transcriptions were studied after induction of λ*c*Its857 prophage at 42 °C, in the absence of DNA replication and in *cro*$^-$ compared with *cro*$^+$ conditions.

In the *dnaB*$^-$ condition (Fig. 2*c* and *d*) or for P^- prophage in *dna*$^+$ host (to be published elsewhere) there is a perfect correlation between the *imm* transcription and *oop* RNA synthesis, since both are blocked after induction. This is not a general effect on transcription because the major leftward p_L transcription remains high (refs 11–12 and present data).

In *dnaE*$^-$ lysogens the perfect correlation between the *imm* and *oop* transcriptions was only observed in *cro*$^-$*c*II$^+$ conditions (Fig. 2*a* and *b*). In *cro*$^+$*c*II$^+$ and *cro*$^+$*c*II$^-$ lysogens the *imm* transcription, but not *oop* RNA synthesis, is eliminated. A somewhat intermediate situation is observed for the *cro*$^-$*c*II$^-$ prophage.

These data enable the following conclusions to be made. Synthesis of the *c*I RNA after induction depends in the same manner as that of the *oop* RNA on host and phage replication functions, such as *dnaB* and *P*, respectively. The *cro* product, an immunity-specific negative regulator, blocks selectively the *c*I transcription, thus decoupling it from the *oop* RNA synthesis. Not only does the *c*I transcription depend on the same factors as the *oop* RNA synthesis, but its full expression also requires the *c*II function. In *cro*$^-$ conditions, some *c*I transcription is observed even in the absence of the *c*II function.

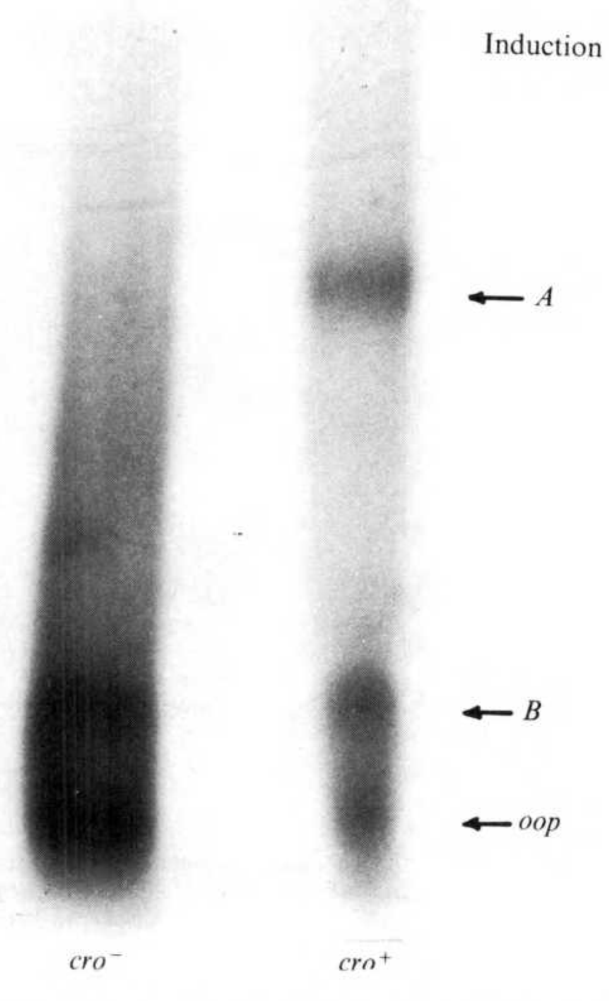

Fig. 3 Autoradiograms of λ RNA fractionated by polyacrylamide gel electrophoresis. The *dnaE*ts(λ*c*I857*cro*$^+$) and *dnaE*ts-(λ*c*I857*cro*27) lysogens were grown to $A_{575} = 0.35$ in MCGB medium[11] enriched with 0.4% yeast extract and 20 μg thymidine ml^{-1}. The cells were spun down, washed twice, resuspended in 10 mM $MgSO_4$ at 5×10^9 cells ml^{-1}, shaken 60 min at 30 °C and transferred to 20 ml labelling medium containing 25 mCi ^{32}P and prewarmed to 42 °C (see ref. 21). The RNA labelled from 0 to 20 min at 42 °C was extracted, heated to 80 °C for 4 min to dissociate any double-stranded RNA, hybridised to *l* strands of λ*bio*30-7 DNA (4 h at 40 °C in 50% formamide), collected on B6 nitrocellulose filters (Schleicher & Schuell), and eluted as described in ref. 21. The eluted ^{32}P-RNA was ethanol precipitated (3 volumes, overnight at −20 °C) and then dissolved in 30 μl buffer E (90 mM Tris, 8.9 mM H_3BO_3, 2 mM Na-EDTA, *p*H 8.3) containing 6 M urea, 0.1% bromphenol blue, and 20% (v/v) glycerol. The samples were layered on to a 3.5% polyacrylamide slab gel[22], and electrophoresed for 8–10 h at 25 mA in buffer E. X-ray film (Kodak NS54T) was exposed for 45 min to slabs contained in polyvinyl chloride wrap.

These results show that the establishment mode of *imm* RNA synthesis after prophage induction could be an extension of the *oop* transcription. At least two-thirds of this *imm* transcription seems to depend on the *c*II product and is completely blocked by the *cro* product. To distinguish between two alternatives—that of a single extended *oop*-*c*I transcript against the possibility that the *oop* and p_{re}–*c*I RNAs represent two separate but jointly regulated transcripts—it was necessary to isolate and characterise the RNA synthesised in the *oop*–*c*I region.

Isolation and characterisation of the elongated *oop*–*c*I RNA

The leftward RNA transcribed in the *c*I–*oop* region was isolated in two steps. RNA labelled with ^{32}P for 0–20 min after thermal induction of *dnaE*ts(λ*c*I857*cro*27) was first prehybridised in 50% formamide 40 °C to *l* strands of λ*bio*30-7 (Fig. 1), eluted, and then fractionated on a 3.5% polyacrylamide gel. The three major bands seen in Fig. 3*a* are: band *A* (about 9S), a plausible candidate for the *imm* RNA, band *B* (about 5S) probably originating in the *b*2 region and not further characterised, and band *C* (about 4S) identified as *oop* RNA. Only RNA bands *B* and *C* are produced by the induced *dnaE*ts(λ*c*I857*cro*$^+$) lysogen (Fig. 3*b*). The startpoint of RNA corresponding to the band *A* was determined by transcriptional mapping[8], and found to be located at about 80.1% λ units on the mature λ map, just to the right of the *imm*21 boundary (Fig. 4). Since this site is also the startpoint of *oop* RNA (ref. 8), we conclude that band *A* is the elongated *oop* transcript corresponding to the establishment immunity transcript.

This conclusion was corroborated by several additional experiments.

By prehybridisation to λ*bio*30-7 *l* strands followed by RNase treatment, the *oop*-*c*I-*rex* establishment immunity RNA was deliberately truncated to about 1,070 bases (2.3% λ units from the startpoint of *oop* to the *bio*30-7 endpoint; (see Fig. 1) which enabled it to enter the 3.5% polyacrylamide gel. The behaviour of this *oop*–*imm* transcript could be changed by either shortening it to about 900 bases or lengthening it to about 2,150 bases by prehybridisation to λ*bio*t124 or λ*bio*t75 *l* strands, respectively (Fig. 1). As expected, prehybridisation to λ*bio*t124 increases slightly the mobility of band *A* (gel not shown). The shortened transcript has the same startpoint at about 80% λ (Fig. 4). On prehybridisation to λ*bio*t75, the resulting RNA does not enter the 3.5% gels, but forms a band in the 2% polyacrylamide gel reinforced with 0.5% Agarose (gel not shown).

The complete absence of band *A* in the 3.5% gel and the presence of only one band *A* in the 2% gel after prehybridisation to the *l* strand of λ*bio*t75 DNA proves that band *A* (Fig. 3) corresponds to a single *oop*–*c*I RNA species, and not to two separate *oop*–*c*II and p_{re}–*c*I transcripts, fortuitously of roughly equal length.

As an alternative to the gel fractionation step, the *imm* RNA was also isolated as material excluded from the Sephadex G-75 column. As shown in Fig. 4, the startpoint of this RNA is also at about 80% λ.

Although we did not observe any *imm* RNA after induction of λ*cro*$^+$ lysogens, it is known that the immunity establishment pathway is observed early after infection with λ*cro*$^+$ phages[2, 3]. We therefore looked for band *A* after infection of *Escherichia coli dnaE*$^-$ with λ*c*I857*cro*$^+$. Band *A* (gel not shown), which corresponds to the joint *oop*–*c*I transcript as determined by transcriptional mapping (Fig. 4), is produced early after infection with either λ*cro*$^+$ or λ*cro*$^-$ but not with λ*cro*$^+$*c*II$^-$ or λ*cro*$^-$*c*II$^-$. The appearance of the *oop*–*imm* RNA early after infection but not after induction (Figs 3 and 4) might reflect the presence of some prophage products, possibly *rex* or traces of *cro*, at the time of induction, whereas after infection they might reach the critical concentration only after some delay.

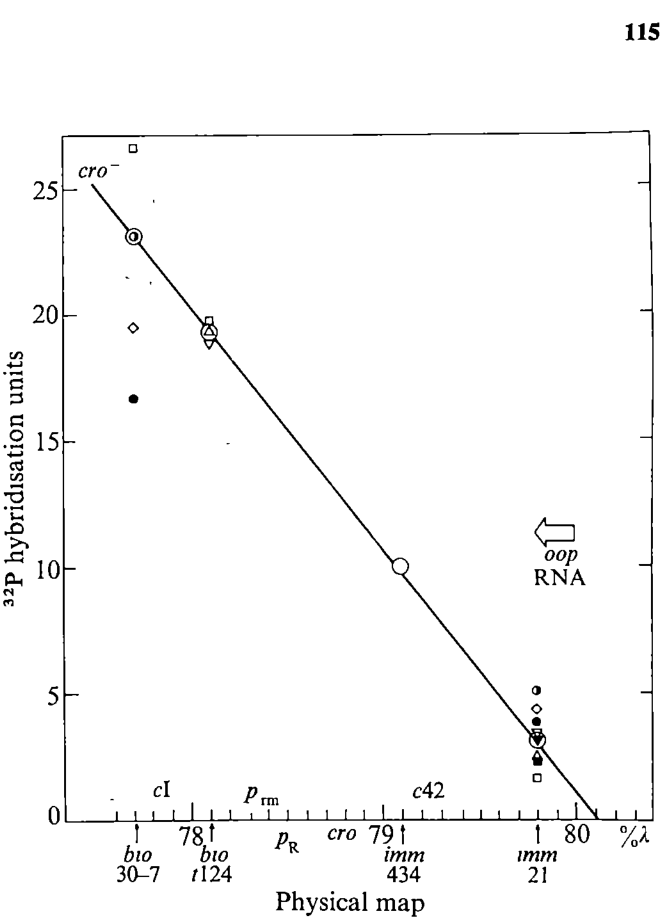

Fig. 4 The transcriptional mapping of the startpoint for the physically isolated immunity establishment RNA. ^{32}P-RNA corresponding to band *A* (see Fig. 3*a*) was isolated from the corresponding slice of the polyacrylamide gel by extraction with NTE buffer (0.3 M NaCl, 10 mM Tris-HCl, *p*H 8.1, and 1 mM Na.EDTA) for about 10 h at 4 °C, followed by ethanol precipitation of the RNA and redissolving in 1 ml NTE buffer. This RNA was hybridised to 10 µg *l* strand DNA of φ80λ*imm*λ (φ80*att*80*imm*λ; hy5) and its *imm*434 and *imm*21 derivatives specified in Fig. 2, as well as of φ80, φ80*hy*42, λ*rep*P22 and P22*rep*λ, in 0.4 ml NTE buffer containing 50% (v/v) formamide, at 40 °C for 4 h. After addition of 10 µg tRNA carrier, the nucleic acids were precipitated with 3 volumes ethanol (−20 °C, overnight), spun down, and redissolved in 0.4 ml NTE buffer. After addition of 0.4 µg pancreatic RNase, the solution was incubated for 15 min at 37 °C, supplemented with 10 ml 2×SSC, slowly filtered through B6 filters (see Fig. 3), and the radioactivity of the ^{32}P-RNA–DNA hybrids bound to the filters counted. Similar hybridisations were carried out with bands *A* obtained in other experiments and with the analogous *imm* RNA isolated as the fraction excluded from the G-75 Sephadex column. ^{32}P-RNA counts hybridising to φ80λ*imm*λ were plotted at the *bio*30-7 or *bio*t124 endpoint position on the abscissa, depending on which of these two λ*bio l*-strand DNAs was used for the prehybridisation of the extracted RNA before its fractionation. The *imm*434 and *imm*21 endpoint positions refer to the hybridisation values obtained with φ80λ*imm*434 and φ80λ*imm*21, respectively. After subtracting the φ80 or φ80*hy*42 background values, all hybridisation values were normalised to the φ80λ*imm*434 value taken as 10 units (see ordinate). □,◇, Induction of the E486(λ*c*I857*cro*⁻) lysogen;RNA prehybridised to λ*bio*30-7 (band *A*, Fig 3, in duplicate). ▽,▼,△, Induction of the E486(λ*c*I857*cro*⁻) lysogen; RNA prehybridised to λ*bio*t124 (band *A*, not shown, in triplicate). ◑,●, Infection of the E486 host with *cro*⁻ and *cro*⁺ λ*c*I857 phage multiplicity of infection 8) respectively;RNA labelled for 0–5 min after infection at 42 °C and prehybridised to λ*bio*30-7 (band *A*, not shown) ■, Induction of the E486(λ*c*I857*cro*⁻) lysogen;RNA prehybridised to λ*bio*t124 (fraction excluded from G-75 Sephadex column with 0.1 M ammonium acetate, *p*H 4.5 as solvent). ○, Average of all results with λ*cro*⁻(λ*c*I857*cro*27). Abscissa corresponds to the physical map of phage λ (see Fig. 1 and ref. 16).

Preliminary fingerprints of that portion of band *A* RNA which hybridises to φ80λ*imm*21 DNA indicate that this 5′-proximal sequence is identical to that of *oop* RNA (refs 20 and 21), (to be published elsewhere).

oop leader sequence and its dual role: p_0 compared with p_{re} promoter

The present study indicates that *oop* RNA can serve as a leader sequence and can be extended into the immunity transcript. This concept of termination–anti-termination (or attenuation) was known in λ transcription (see, for example, ref. 6) and later found in other operons[23,24]. Such a mechanism was postulated as one of the alternatives when *oop* RNA was first characterised[6,13,14]. Our results now make it unnecessary to invoke the presence of a p_{re} promoter to explain the *cis*-dominant effect of the *c*42 and other *c*Y mutations in the *y* region[2,3,25,26] (Fig. 1). The *c*Y mutations might represent either some polar blocks or inactivation of one of the sites at which the *c*II and *c*III products act as anti-terminators and enable the extension of *oop* RNA into the *imm* transcript. The latter explanation seems less likely, since the *c*II product is still required for suppression of the *c*Y defect by the *sar* mutation[10]. This subject is now being studied. Note that the p_0 promoter region and the *c*III product are in common for phages λ and λ*imm*21(hyl)[27], but the *c*II products differ. If the anti-terminating action of the *c*II protein depends on DNA sequence specificity, the first divergence in the sequence between λ and λ*imm*21 is at about 60 nucleotide pairs from the 5′ end of *oop* (M. Rosenberg, personal communication). It might be relevant that recognition for the N product, as defined by the *nut*L mutations, is over 30 nucleotide pairs downstream from the p_L promoter of λ (J. S. Salstrom and W. Szybalski, cited in ref. 17).

The simplest model consistent with the present and previous data is that *oop* RNA may serve a dual role, both as a primer for λ DNA replication[15] and as a primer or leader for the immunity establishment transcription. In conditions which presumably favour early *cro* expression, only short species of *oop* RNA would be synthesised, and this abundance of a primer for the initiation of DNA synthesis would channel the phage into the lytic cycle, which requires extensive λ DNA replication. Alternatively, probably when *cro* gene expression is slightly delayed or depressed, the availability of the *c*II and *c*III products would favour the elongation of the *oop* RNA into the *imm* transcript. This would lead to a burst of repressor synthesis and consequently channel the phage into the lysogenic pathway and establishment of the prophage state. It is interesting that the recently described *sar* mutation, which maps in the *oop* region, seems in certain conditions to favour the lysogenic pathway while depressing DNA synthesis[10].

Although this study has demonstrated new important features of the establishment mode of the immunity transcription, future work is needed to elucidate the function of the *y* region and the specific mechanisms by which the *cro*, *c*II and *c*III products regulate the elongation of the *oop* RNA into the *imm* transcript.

This work was supported by the NCI, We thank John S. Salstrom and Eric C. Rosenvold for discussions, and Lois Wilson for assistance with the preparation of DNA strands and Annelie James with the RNA fractionation. We also thank Drs G. Gussin, A. Oppenheim, A. B. Oppenheim and H. Echols for critical reading of the manuscript and comments.

letters to nature

Sigma Orionis E as a mass-transfer binary system

SIGMA Orionis E, the first He-rich B star discovered[1,2], was recently found[3,4] to have an extremely broad (~ 1,800 km s^{-1}), rapidly varying Hα-emission feature. From independent spectroscopic, spectrophotometric, and photometric observations on 4 consecutive nights in December 1974, we have shown[4] that it is a variable, with $P \simeq 1.19$ d; however, incomplete phase coverage in those data, as well as uncertainty about the nature of the periodicity, has hampered the development of a model to account for the wealth of observed phenomena. Here we briefly communicate results of new continuous *uvby*β photometry carried out during the 11 consecutive nights December 28, 1975–January 7, 1976 (UT), together with some possible interpretations.

The observations were made with a single-channel, refrigerated, pulse-counting, 1P21 photometer on the number 1 0.4-m telescope of the Cerro Tololo Inter-American Observatory. As in the December 1974 observations, CTIO filter set number 3 was used throughout; however, for the new data differential photometric techniques were employed. The comparison star was HR1861, a *uvby*β standard star[5,6] with colours nearly identical to those of σ Ori E and ~ 1° away. Ten-second integrations were used. An observation, requiring ~ 5 min for completion, consisted of the measures: *y*,*b*,*v*,*u*,βW,2βN, recentre, and repeat in reverse order, where W and N refer to the wide and narrow Hβ filter, respectively. The nights were essentially moonless and sky readings were taken regularly throughout. Errors from photon counting statistical effects were < 0.007 mag in all observations. Differential extinction corrections were applied to the *uvby*β data with coefficients determined each night, except for 2 nights, greatly shortened by clouds, for which the means of the immediately adjacent nights were adopted. The Hβ data were reduced using the well known mean slope coefficients for the filters and a nightly determination of the zero point correction based on HR1861.

The resultant light and colour curves, of which those for *y*, *u*, and $u-b$ are given in Figs 1*a–c*, show two distinct minima. By comparison of the depths, particularly in *u*, we conclude that the minimum near phase $\varphi \simeq 0.63$ (hereafter called primary minimum) is the same as that observed[4] in December 1974. A primary minimum occurred in the new observations[7] at JD 2442778.819, which combines with the December 1974 data to yield an improved estimate of the period: 1.19080±0.00005 d. This value is in excellent agreement with one possible period, 1.19086 d, found from a comparison of the December 1973–January 1974 spectroscopic[3] and the December 1974 spectrophotometric[4] Hα-emission data; this agreement suggests that the period may be reasonably stable over a 2–3 yr interval.

Among the characteristics of the rather peculiar light curves, we point out the following: (1) The secondary minimum follows the primary by $0.43P$ (12.4 h), and the widths of both are ~ 3.0 h at half-depth. (2) The amplitudes of the minima are considerably greater in the ultraviolet, and the depths in *y*, *b*, *v*, and *u* of the primary (0.07, 0.06, 0.05, and 0.15 mag) and secondary (0.04, 0.04, 0.03, and 0.12 mag) minima vary non-monotonically with wavelength. The amplitudes of the $u-b$ colour minima are, however, similar. (3) The minima are asymmetrical, with the ingress into secondary minimum more gradual (by a factor of ~ 2) than the other transitions. (4) The light level outside the minima is not constant but seems to decline continuously between successive secondary minima, although the *v* light level is more irregular. With respect to December 1974 the mean magnitude levels at $0.8P$ have remained nearly constant in *y* and *b*, but the *u* level is brighter by ~ 0.04 mag in 1975–76; this observation suggests that secular changes with a colour dependence similar to that of the periodic ones may occur. (5) The Hβ phase diagram shows behaviour strongly reminiscent of that of W_{abs} (Hα) in Fig. 4 of Walborn and Hesser[4], which suggests that weak, variable emission is present at Hβ. Comparably detailed observations of more cycles are required to ascertain the permanence of the foregoing features in the light and colour curves, but correspondences between the December 1974 and 1975–76 data indicate that some of them are reasonably stable.

The general appearance of the light curves of σ Ori E, and that of the Hα profile when the emission is strong, are strikingly similar to observed properties of the dwarf nova system U Geminorum[8,9]. These properties are interpreted in terms of a mass-transfer binary in which a collapsed (white dwarf) component is surrounded by a rapidly rotating accretion disk containing an ultraviolet-bright spot with energy provided by the impinging stream of gas from the other star[10,11]. It is evident that a similar model could account for most of the principal characteristics of the light, colour and spectrum variations in σ Ori E. Particular reference is made to the illustration and discussion by Lin[12]. The primary minimum occurs when the hot spot is occulted by the B star, whereas the secondary minimum is caused by occultation of the spot by the optically thick disk itself. Since the spot is located on the following side of the disk, the secondary minimum will follow the primary by < $0.5P$, as observed. Moreover, since the line-emitting region is downstream from the hot spot in the disk, the principal Hα-emission maximum should follow inferior conjunction of the disk and have $V > R$, again as observed[4]. We note, however, that this model requires synchronous

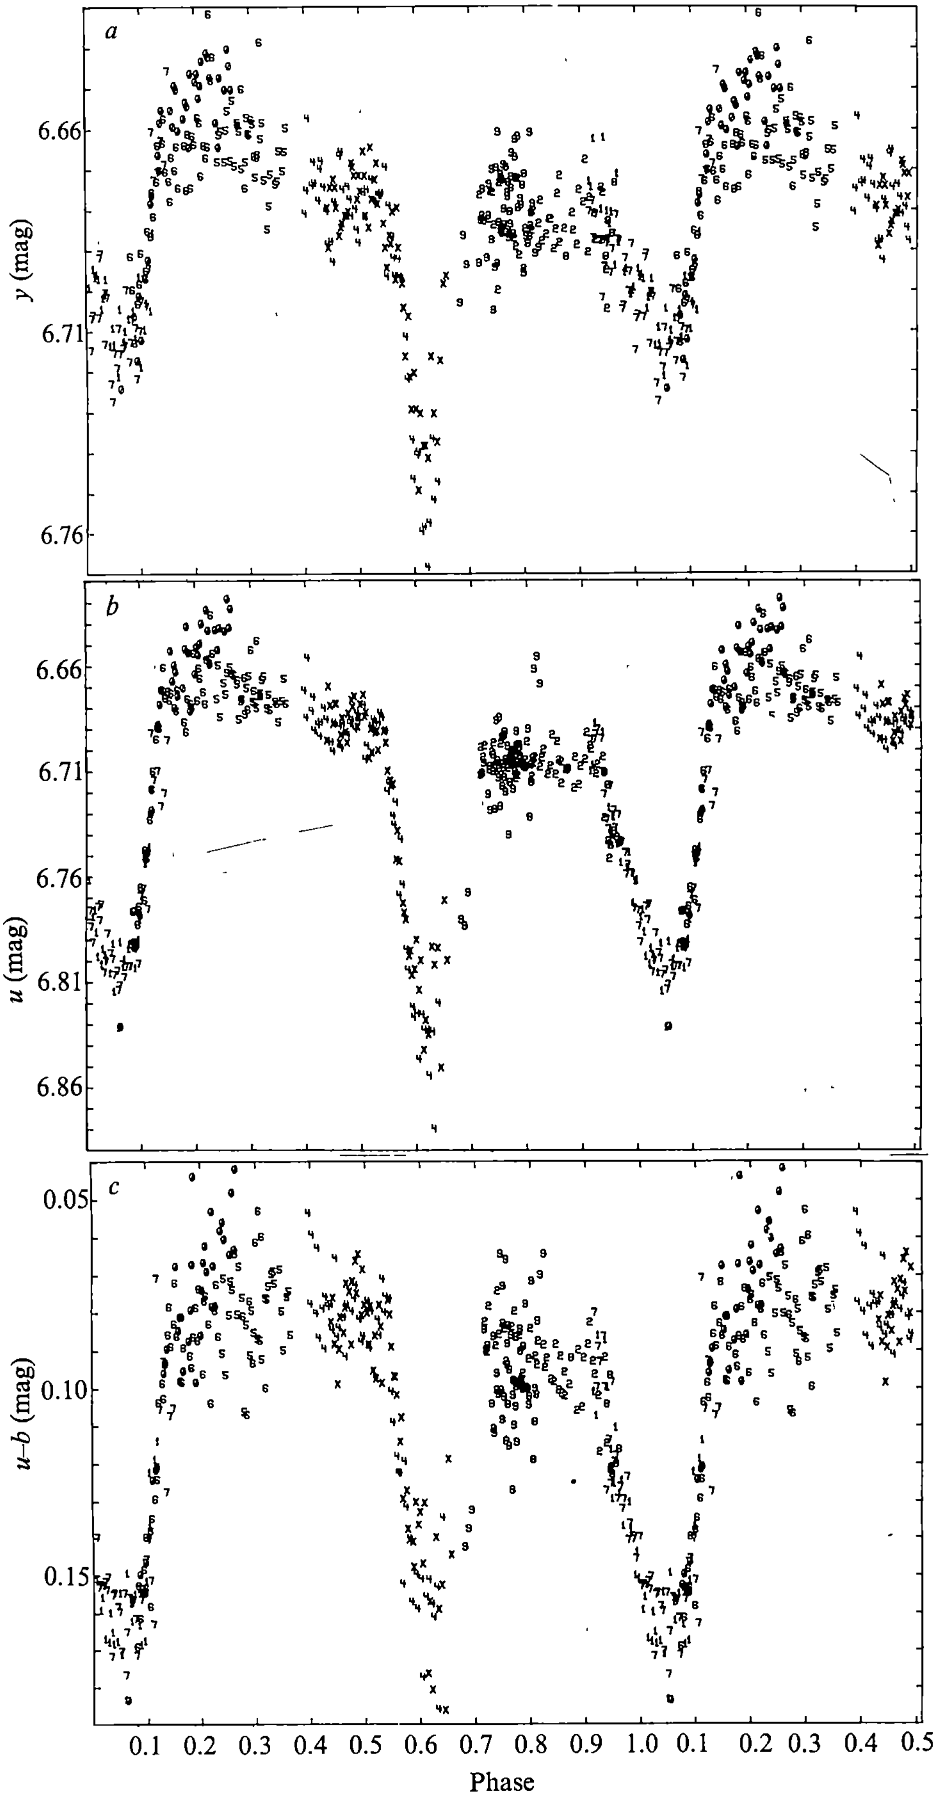

Fig. 1 *a–c*: *y*, *u*, and *u*–*b* light and colour curves for σ Ori E from the 1975–76 data, with 1975 December 28.0 = JD 2442774.5 as zero phase and a period, 1.19082 d, that differs insignificantly from the finally adopted value, 1.19080 d. The symbols serve to distinguish data from different nights: 0–9 correspond to December 28–January 6 and × to January 7. Because of occasional high humidity during the observations, it is uncertain if some fine details of the light curves (for example, the tendency for night 0 (28 December) to lie somewhat brighter than those of nights 5 or 6 at φ ≃ 0.2) arise from stellar variations or to slightly inaccurate differential extinction corrections The *u*–*b* colour is (normally) a reliable temperature indicator for B stars

rotation and a stable, inhomogeneous surface composition for the B star to explain the behaviour of the He line[4,13].

Bolton's[14] upper limit to the radial velocity variation of σ Ori E implies that any companion must have a mass $\lesssim 0.1 M_\odot$ for inclinations > 45°. Thus the secondary would be an M dwarf or a collapsed object. The latter alternative would be in agreement with the above model, as well as providing a ready explanation for the helium enhancement (or hydrogen deficiency) at the surface of σ Ori E in terms of a prior episode of mass transfer from an originally more massive companion. Since σ Ori E is located in a Trapezium-like system containing a 09.5-V component[2], the mass of the original primary in the mass-transfer binary picture would have been $\gtrsim 20 M_\odot$.

If this model is correct, high-frequency optical monitoring of σ Ori E might provide additional information; only one such study has been made at CTIO, before the development of the present working picture, and hence at a rather low sampling frequency. Beginning at 1974 December 6.084 UT, σ Ori E was monitored at Hα for 6 h with the 3-channel photometer at the 0.9-m telescope. A 20/80% neutral beamsplitter, 2 FW 130 (S20) photocells, and KPNO filters 210 ($\Delta\lambda = 159$ Å) and 71 ($\Delta\lambda = 54$ Å) were used for 2-s integrations. A total of 8,192 integrations was processed with power spectral techniques[15]; no peak > 0.0013 mag was found in the period range $4.0 < P <$ 1,640 s for the sampled phases.

While this paper was in preparation, an alternative but related interpretation of the light curves of σ Ori E occurred to one of us (N.R.W.) after reading the new results on Algol[16]. The alternative model follows from interpreting the two minima in σ Ori E as components of a single 'W-shaped' eclipse; indeed, the resulting ingress–egress symmetries strongly support the correctness of such an interpretation. In this case one is led to consider two ultraviolet-bright spots, most probably located at the equilateral Lagrangian points of the binary system, with the leading spot somewhat the brighter. 'Mid-eclipse' occurs at $\varphi \simeq 0.83$, with both Lagrangian points visible. The mass ratio condition for the existence of stable, equilateral Lagrangian points implies an upper limit to the secondary mass of the same order as that resulting from the radial velocity observations. If a plausible model with $\mathcal{M}_1 = 8 M_\odot$, $\mathcal{M}_2 = 0.1 M_\odot$, and centre-to-centre separation of two primary radii is assumed, the resulting geometry is strikingly simple, and many features of the light and colour curves are explained in a straightforward manner.

The implications of this model of σ Ori E for current theories of stellar evolution in massive binaries are sufficiently significant to justify extensive further observations. Most critically needed are high-accuracy radial velocities throughout the full 1.19 d cycle, preferably with simultaneous photoelectric monitoring. In addition, polarimetric, X-ray and radio observations of both moderate- and high-time resolution may provide key information for the evaluation of the proposed working model.

J.E.H. thanks Dr John Irwin for relinquishing a crucial night of telescope time; Sr. Guido Garay for programming assistance and the Yale University Observatory for their hospitality while this paper was being written. The Cerro Tololo Observatory is operated by the Association of Universities for Research in Astronomy, Inc., under contract with the NSF.

Evidence for a radioactive decay hypothesis for supernova luminosity

VAN HISE[1] has observed that the light curve for the Type I supernova 1937c is well represented by a sum of two exponentials with half lives which are ~0.75 the half lives of ^{56}Ni and ^{56}Co in the β-decay chain $^{56}\mathrm{Ni} \rightarrow {}^{56}\mathrm{Co} \rightarrow {}^{56}\mathrm{Fe}$. Colgate and McKee[2] had previously suggested this chain as a source of supernova luminosity, but the hypothesis was not widely accepted because of the variability of the decay rates of supernova light curves and because the interstellar medium would be overabundant in heavy elements. This letter presents observational evidence supporting a model of Leventhal and McCall[3] which overcomes these difficulties.

According to this model, a Type I supernova produces a white dwarf containing $\sim 0.2 M_\odot$ of ^{56}Ni. At terrestrial densities the decays of ^{56}Ni and ^{56}Co occur by capture of an inner shell electron 100 and 80% of the time, respectively, but in the interior of a white dwarf, the bare nuclei move through a Fermi sea of electrons, and the higher electron densities thus encountered would produce an enhancement of the decay rates. The supernova luminosity is given by

$$L(t) = A_1 \exp(-t/T_1) + A_2 \exp(-t/T_2) \qquad (1)$$

where T_1 and T_2 are the half lives of the steep, earlier and the flat, later portions of the light curve, and A_1 and A_2 are parameters whose values depend on the initial amount of ^{56}Ni, the energy releases per decay of ^{56}Ni and ^{56}Co, and the values of T_1 and T_2. If the model is correct, T_1 should not exceed the terrestrial half life of ^{56}Ni (8.8 d), T_2 should not exceed that of ^{56}Co (112 d), and the two should be related approximately by

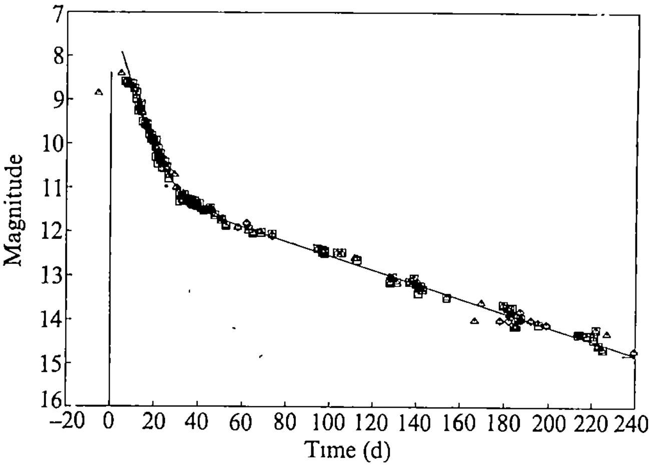

Fig. 1 Sum of exponentials fit to the light curve of SN1937c. The vertical line at $t = 0$ represents the estimate m_0 of peak apparent magnitude. □, Baade and Zwicky[9]; △, Parenago[10]; ◇, Deutsch[11]. For the values of the parameters of the fit see Table 1.

$$\frac{T_1}{8.8} = \frac{T_2}{112};\ T_2 = 12.7\,T_1 \qquad (2)$$

More precisely, according to Leventhal and McCall[3], at

high matter densities the ^{56}Ni and ^{56}Co decay rates (d^{-1}) are given by

$$R_{Ni}=\frac{1}{8.8}\left(\frac{\bar{\rho}_{av}}{9.7\times10^{28}}\right)(1+0.61\times10^{10}\,\bar{\rho}_{av}^{-1/3})$$

$$R_{Co}=\frac{1}{558}+\frac{1}{139.4}\left(\frac{\bar{\rho}_{av}}{8.6\times10^{28}}\right)(1+0.60\times10^{10}\,\bar{\rho}_{av}^{-1/3})$$

where $\bar{\rho}_{av}$ is the electron density (cm^{-3}), 8.8 and 112 d are the terrestrial 1/e lives of ^{56}Ni and ^{56}Co, 9.7×10^{28} and 8.6×10^{28} cm^{-3} are the electron densities at Ni and Co nuclei in the terrestrial environment, and 1/558 d^{-1} represents the fraction (20% on Earth) of Co decays which involve positron emission. It is assumed here that the positron emission rate is unaffected by high densities. At low densities, electron binding occurs, so the effective decay rates can be calculated by the interpolation equations

$$T_1=\left[\left(\frac{1}{8.8}\right)^2+R_{Ni}{}^2\right]^{-1/2}$$

$$T_2=\left[\left(\frac{1}{112}\right)^2+R_{Co}{}^2\right]^{-1/2}$$

which define a curve well approximated by the straight line, equation (2).

Rust[4] has recently collected 37 Type I light curves from the literature and used techniques developed by Pskovskii[5,6] to reduce them to a common photometric system (the m_{pg} system). Fifteen of the curves were complete enough to give reasonable fits using a sum of two exponentials. The others did not extend far enough to define the more slowly decaying exponential.

The light curves consisted of measurements of apparent magnitude $m(t)$ versus time. Apparent magnitude is related to luminosity by

$$\frac{L(t)}{L_0}=10^{-0.4[m(t)-m_0]} \qquad (3)$$

where L_0 and m_0 are the luminosity and apparent magnitude at maximum brightness. Taking the moment of peak brightness as the zero-point of time and combining equations (1) and (3) gives

$$10^{-0.4[m(t)-m_0]}=\frac{A_1}{L_0}\exp(-t/T_1)+\frac{A_2}{L_0}\exp(-t/T_2) \qquad (4)$$

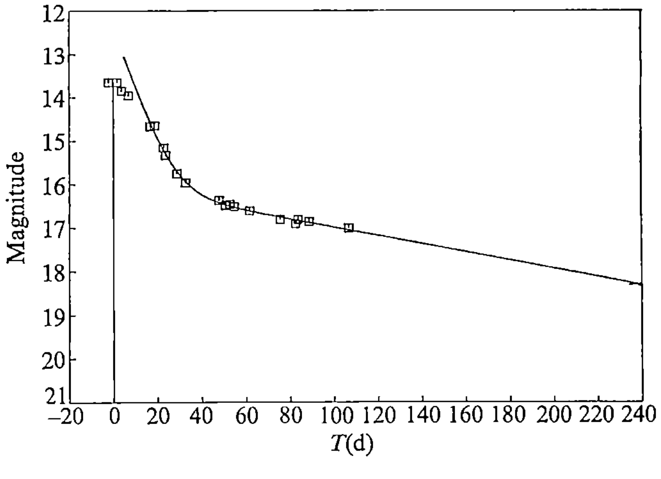
The values of T_1, T_2, (A_1/L_0) and (A_2/L_0) were determined for each light curve by nonlinear least squares fitting of this equation beginning a few days after peak brightness to assure that only the decay portion contributed to the fits. The method used was a damped Gauss–Newton iteration.

The results of the fits are given in Table 1. The standard deviations were estimated from the covariance matrix but should be regarded only as approximations (see ch. 7, ref. 7). The values were checked by repeating the fits using the separable parameter algorithm of Golub and Pereyra[8].

For all light curves in the sample the fitted curves represented the data points well and gave low values for the sum of squares of residuals, but only if the data were very complete did the fits specify the parameters with high certainty. This is illustrated in Figs 1 and 2 which represent one of the best and one of the worst fits. In both cases the curves accurately represent the data, but for SN1962j, $\sigma(T_2)$ is very large relative to T_2. The condition that the s.d. of both 1/e lives be less than the parameter values themselves provided a criterion for rejecting incomplete light curves from the sample.

Figure 3 is a plot of T_2 against T_1 with the error bars representing 1 s.d. The vertical and horizontal dashed lines represent the upper limits imposed by the terrestrial values. Only one point lies >1 s.d. beyond these limits, that point being ~ 2 s.d. out. Furthermore, there is a definite tendency for the points to lie along the predicted line $T_2 = 12.7\ T_1$ which is shown as a diagonal. Although the scatter is large, the correlation coefficient is $r = 0.529$, implying, at the 97.5% level of significance, that the data follow a non-random relationship. The average values of $\sigma(T_1)/T_1$ and $\sigma(T_2)/T_2$ are 0.13 and 0.43, a fact which invalidates both a standard regression of T_2 on T_1, which would

Fig. 2 Sum of exponentials fit to the light curve of SN1962j. Data points are taken from Bertola[12].



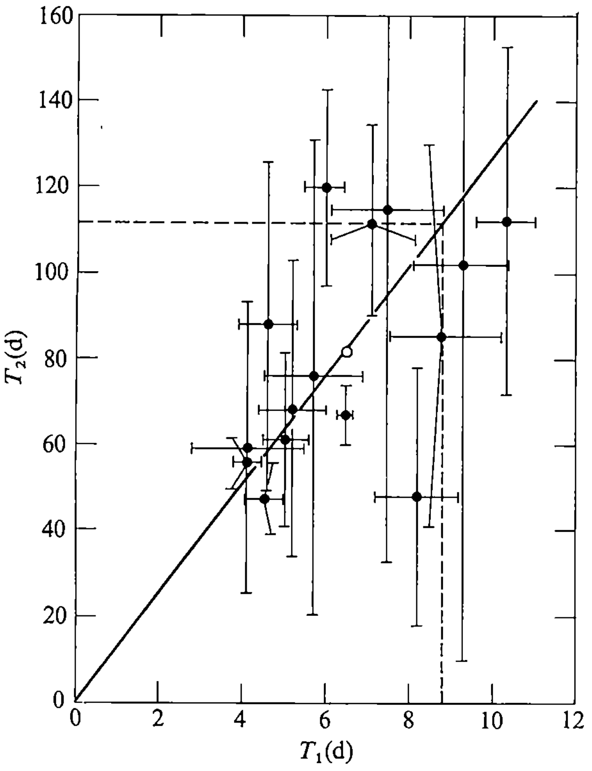


Fig. 3 Plot of the fitting parameters T_2 against T_1. The error bars represent the estimated s.d. but should not be interpreted as the major axes of error ellipsoids because the errors in T_1 and T_2 are correlated in each case.

assume the errors in T_1 are insignificant, and a major-axis regression, which would assume approximately equal errors in T_1 and T_2. It is, however, possible to use the computer generated T_1,T_2 variance matrices to obtain a maximum likelihood estimate of the best linear representation of the data (see ch. 4, ref. 7). The likelihood function can also be used to construct confidence regions in the space of the two parameters, that is, slope and intercept (ch. 7, ref. 7). When this procedure was applied to the data the point defined by equation (2), that is, slope = 12.7, intercept = 0, was found to lie well inside the 50% contour. This shows that the data are consistent with the predicted relation. A more dramatic measure of this consistency is furnished by the average values of T_1 and T_2 which are

$$\overline{T_1} = 6.46 \pm 1.98$$
$$\overline{T_2} = 81.2 \pm 25.7$$

where the indicated errors are the s.d. The point represented by these values is shown in Fig. 3 as an open circle lying almost exactly on the predicted line. These results constitute significant evidence supporting the $^{56}Ni \rightarrow {}^{56}Co \rightarrow {}^{56}Fe$ decay hypothesis. Furthermore, if the cold white dwarf model is correct, the fact that no T_2 is < 47 d implies an upper mass limit of $\sim 0.4 M_\odot$ for white dwarfs produced.

The authors would like to thank Ms Barbara J. Handley for assistance with the statistics and Professor Gene H. Golub for his nonlinear least squares program.

Orientation of pulsar magnetic dipole moments

THE angle between the magnetic dipole moment and the spin of a pulsar is an important parameter in studies of the pulse emission. In this letter, arguments based on the properties of the weak interaction between elementary particles and on the superfluidity of the core show that the torque associated with the rotating dipole moment is free to cause alignment with the spin only in pulsars older than the Crab, and possibly the Vela pulsar. On the basis that the sine of the angle follows an exponential law with a time constant of $\sim 10^6$ yr, the observed distribution of radio pulse widths can be explained by the group of models in which emission occurs from regions near the polar caps rather than the light cylinder.

The high electrical conductivity[1] of the interior matter implies that the magnetic field of a pulsar should be fixed with respect to the body axes of the star. The principal moments, and the torque acting on the star, determine the orientation, as a function of time, of the magnetic dipole moment relative to the spin. The torque can be expressed as the sum of three components

$$\mathbf{N} = \mathbf{N}_1 + \mathbf{N}_2 + \mathbf{N}_3$$

where $\mathbf{N}_1$ and $\mathbf{N}_2$ represent the electromagnetic torque and are, respectively, perpendicular and parallel to the magnetic dipole moment **p**. The component $\mathbf{N}_1$ can be approximated by the vacuum torque for the rotating external dipole field, and $\mathbf{N}_2$ represents the torque resulting from current flow between the corotating magnetosphere and the polar caps of the star. The component $\mathbf{N}_3$ represents the dissipative torque, which causes the axis of greatest principal moment to align with the spin. Owing to the temperature- and therefore time-dependence of $\mathbf{N}_3$, the angle ψ between spin and dipole moment is predicted for pulsars with the properties: (1) a mass such that there is no solid core; (2) an internal toroidal magnetic field with symmetry axis approximately colinear with **p**, to have the following time variation. At a time $t_1 \lesssim 10^3$ yr, ψ becomes approximately equal to $\pi/2$ and remains constant until $t_2 \gtrsim 10^4$ yr. For $t > t_2$, $\psi \rightarrow 0$ with a time constant determined by $\mathbf{N}_1$, $\mathbf{N}_2$ and by the values of ψ and of the period P at $t = t_2$. This form of $\psi(t)$ is consistent with the existence of a strong interpulse in the Crab pulsar and, if the slowing of the pulsar rotation is determined mainly by $\mathbf{N}_1$, provides a simple explanation of the secular variation of magnetic dipole moment postulated by Lyne, Ritchings and Smith[2].

This prediction of $\psi(t)$ depends only on general features of superfluidity and of the non-leptonic weak interaction Accurate knowledge of energy gaps or of the equation of state is not required.

At certain radii in the interior, neutrons, protons and Σ^- hyperons are expected to be in equilibrium. The protons[3] form an isotropic BCS superfluid with energy gap Δ. For such densities, the neutrons[4] may have a small anisotropic energy gap. If the proton energy gap alone is considered, the relaxation time for the non-leptonic weak interaction $n+n \rightleftharpoons p+\Sigma^-$ is proportional[5] to $(\beta\Delta)^{-5/2} \exp(\beta\Delta)$ in the limit $\beta\Delta \gg 1$, where $\beta^{-1} = k_B T$. If the spin is not parallel with the axis of greatest principal moment, the matter in the interior is subject to periodic pressure fluctuations having the period of the precession which must occur. As the pulsar cools, the relaxation time must increase until of the order of the precession period so

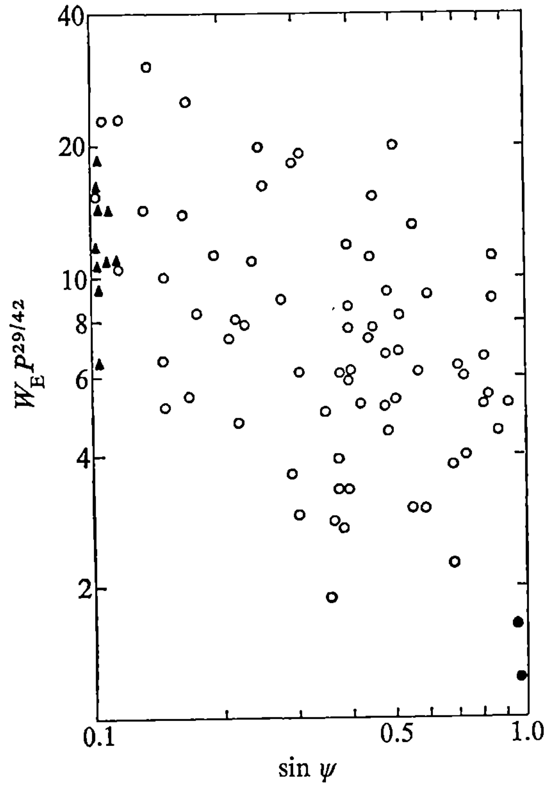

Fig. 1 The distribution of $W_E P^{29/42}$ and sinψ is shown for 82 pulsars, for $\tau_D = 10^6$ yr. The integrated pulse widths W_E, expressed in degrees, are those at 408 MHz listed by Lyne *et al.*[2]. The 10 pulsars with sinψ < 0.1 are shown separately as solid triangles on the left-hand side of the diagram. The Crab and Vela pulsars are likely to have $t < t_2$ and are represented by the two solid circles at the lower right-hand side.

that the coefficient of bulk or second viscosity is extremely large. In the Euler equations, the effect of the viscosity is expressed as a large torque $\mathbf{N}_3$ which causes the axis of greatest principal moment to become parallel with the spin at a time $t_1 \lesssim 10^3$ yr. The effect of a small neutron energy gap would be merely to reduce the value of t_1. Further cooling of the pulsar interior causes the viscosity and therefore $\mathbf{N}_3$ to become negligibly small at times $\sim 10^4$ yr. A more detailed discussion is given elsewhere (P. B. Jones, unpublished).

The distortion caused by the elasticity of the solid outer shell has an axis of symmetry which moves with respect to fixed body axes in such a way as to be approximately parallel to the spin direction. This motion is the result of plastic deformation which occurs for $t \lesssim t_1$ because the temperature is then of the order of 10^8 K and because the rotational surface oblateness greatly exceeds the likely critical strain. Thus the axis of greatest principal moment is determined by the toroidal internal magnetic field and is approximately perpendicular to **p**.

For $t > t_2$, and $\mathbf{N}_1 \gg \mathbf{N}_2$ and $\mathbf{N}_3$, $P \sec\psi$ is a constant of motion and sinψ decreases according to an exponential law with a mean time $\tau_D = P^2 \sec^2\psi(P\dot{P})^{-1}{}_{t=t_2}$. Owing to this alignment of the dipole moment, its component perpendicular to the spin has the time dependence postulated by Lyne *et al.*[2]. Plausible values of P, the period derivative $\dot{P}$, and ψ at $t_2 \simeq 10^4$ yr are quite consistent with $\tau_D \simeq 10^6$ yr given by Lyne *et al.*, whereas if the dissipative torque were neglected, $t_2 = 0$ and the predicted values of τ_D would be too small[6,7] to be consistent with the observed pulsar population.

In one group of pulse emission models[8–10], the microwave radiation is produced tangentially to their velocity by charged particles moving along field lines leaving the polar caps of the star and penetrating the light cylinder. The integrated pulse width is a function of the angle ψ and of the angular size of the emission cone, which is dependent on the period. For the most recent model[10] in this group, $W_E P^{29/42}$ should be proportional to $(\sin\psi)^{-1}$, apart from variations in the intersection of the emission cone by the line of sight. The expression for W_E given by a second group of models[11], those involving relativistic beaming, is very dependent on the velocity of the emitting region and no simple prediction seems possible.

Values of sinψ have been determined from the $\dot{P}$ measurements of Lyne *et al.*[2] for a universal $\tau_D = 10^6$ yr. The distribution of $W_E P^{29/42}$ and sinω shown in Fig. 1, a band of gradient −1, supports the polar cap group of models and the hypothesis that most pulsar magnetic dipole moments are aligning with the spins in a mean time $\sim 10^6$ yr. If the points shown as open circles were normally distributed about a straight line, the gradient of the line would be -0.99 ± 0.15.

Ocean bottom seismic measurements on the East Pacific Rise and Rivera Fracture Zone

WE describe preliminary results of a seismic experiment using ocean bottom seismometer capsules (OBS) in three separate tripartite arrays. The arrays were located on the central topographic high of the East Pacific Rise between the Rivera and Tamayo Fracture Zones (8 d in position), at the junction of the ridgecrest and the Rivera fracture zone (12 d), and on the Rivera fracture zone well away from the ridgecrest (9 d). Accurate locations and depths could be computed for events sufficiently close to each array, and showed that the main transform fault lay within the central trough. OBS capsules have been successfully used for refraction work[1,2] (also B. Lewis and C. Lister, unpublished) and microseismicity studies[3], but we report here the first use of arrays on a spreading centre–transform fault system for event locations. Other questions of importance to seismology can also be answered from these data.

The capsules[4] contain a 1-Hz vertical seismometer and triggered digital recording system. The capsule itself falls freely to the ocean bottom. When triggered acoustically or after a predetermined time, it is released and floats to the surface. An acoustic system facilitates accurate location of the capsule to within several metres relative to a surface ship.

Figure 1 shows sites and epicentre locations for a number of events recorded at arrays 2 and 3. Array 1 (the ridge array) is not shown. Figure 2 shows a sample of seismograms from array 3. At array 2, 105, 680, and 155 events were recorded on the 3 capsules, respectively. Of these, 67, 57, and 37 were recorded simultaneously by each of the three pair combinations of capsules. Thirty-one earthquakes were recorded simultaneously by all three capsules. Some of the events recorded (particularly those on LY), are spurious triggers caused by ground noise. Many, however, are earthquakes too small to trigger all capsules. All events recorded simultaneously on two or more capsules are believed to be earthquakes. At array

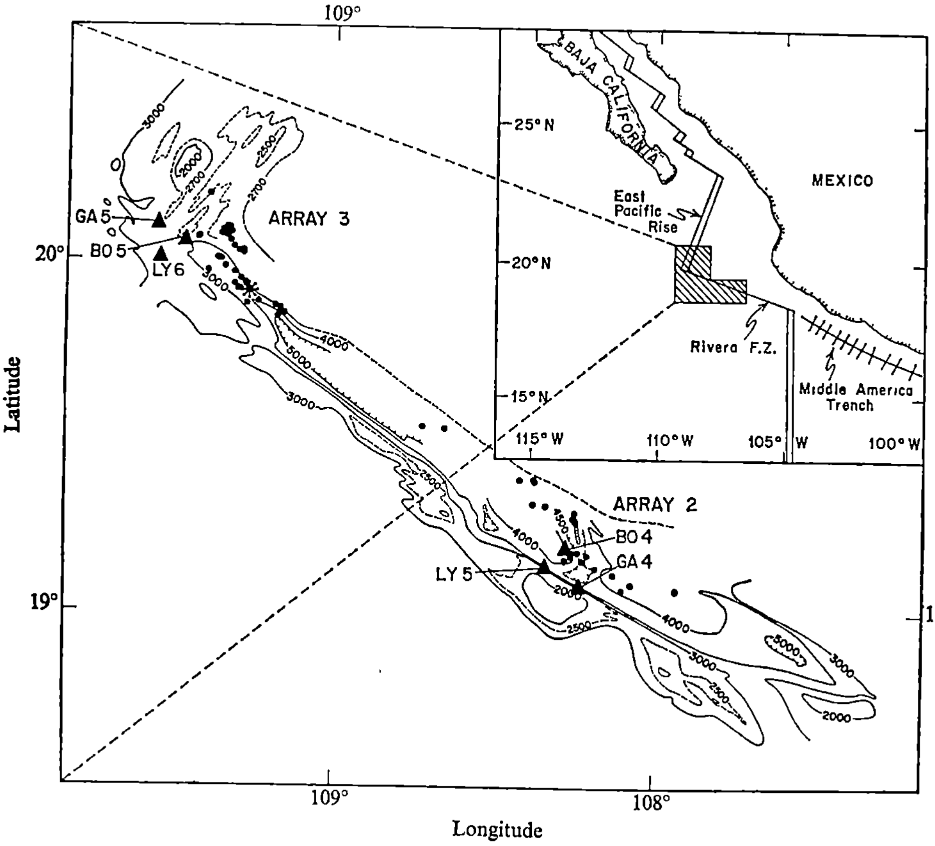

Fig. 1 Capsule sites and bathymetry (m). All of the well determined epicentres recorded at array 2 are shown. A representative sample of events recorded at array 3 are plotted. The asterisk shows the location of the swarm sequence.

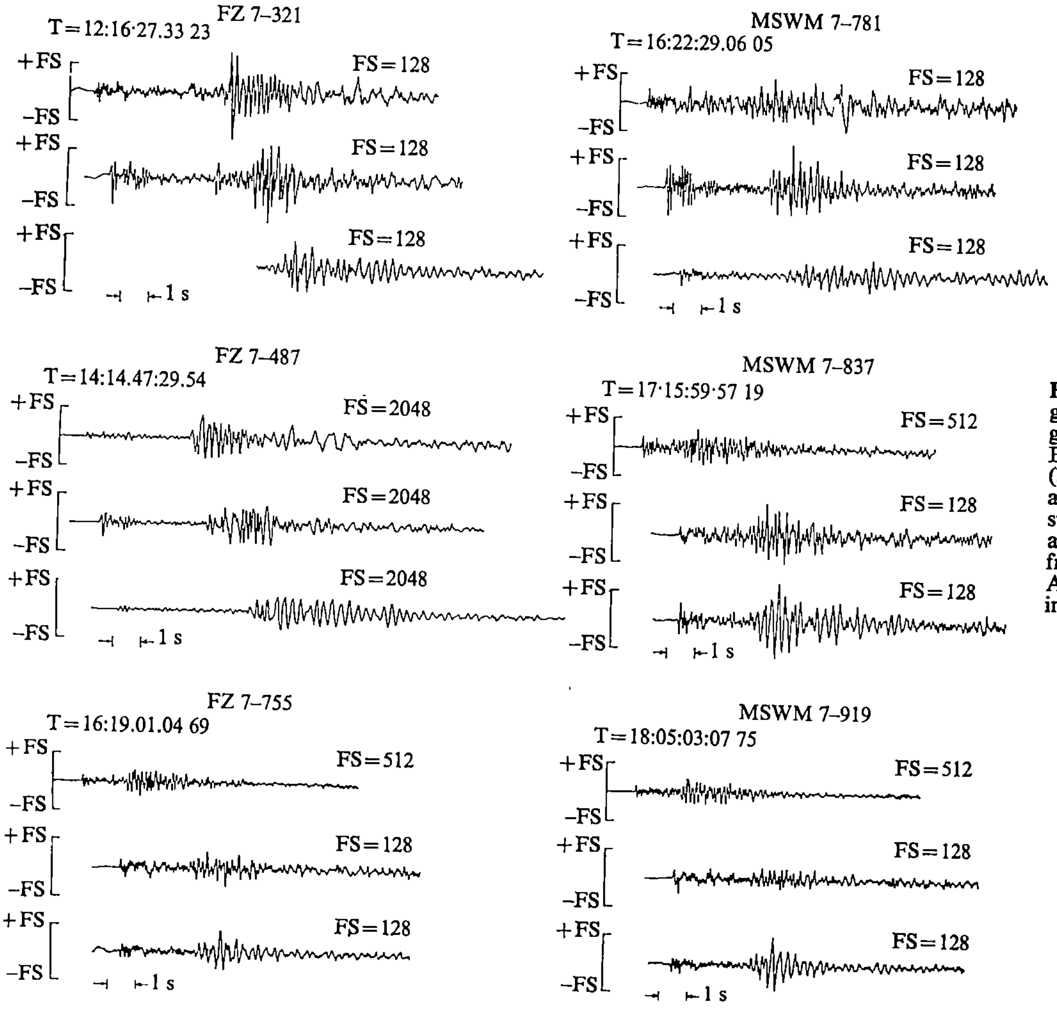

Fig. 2 This shows several seismograms recorded at array 3. Each group of 3 was recorded at BO5(top), LY6(middle), and GA5 (bottom). Events 7–755, 7–783, and 7–919 are from the small swarm sequence due east of the array. The others are down the fracture zone towards the asterisk. At 5 Hz, the seismometer response in counts μm^{-1} is 2.4×10^3. FS on the plot is in counts.

number 3, 254, 304, and 409 events, respectively, were recorded by the capsules. The pair combinations of capsules recorded 196, 213, and 309 events simultaneously. Of these, 183 were recorded on all three capsules. During this period, a swarm of earthquakes with a $M=4.3$, $M=4.3$, and $M=4.8$ sequence, and numerous smaller events, was recorded. The three larger events were recorded on World-Wide Network stations.

The locations of capsules BO and LY were determined by acoustic ranging, and triangulation from the ship, in conjunction with satellite fixes and/or fixes to a moored radar buoy. We estimate the accuracy of these locations to be within 100 m. Capsule GA's transponder failed, so we obtained the best possible estimate of ship position and drift before, during and after the drop. We estimate the location accuracy of GA to be within 400 m.

Epicentre locations and depths were calculated using a half-space location programme written by Ray Buland at IGPP. The locations shown in Fig. 1 were calculated with $V_P=6.5$ and $V_P/V_S=\sqrt{3}$. Seismic refraction results from the East Pacific Rise[5] indicate that this velocity is reached within the top 2 km of crust. For sources a few km deep, as these are believed to be, the half-space model is probably a good approximation as long as the events are near or within the array. Locations of events close to the array were found to be relatively insensitive to changes in velocity. All reasonable values for V_P gave epicentres and source depths which varied by at most 1 or 2 km. The locations of the more distant events varied by several km, but our basic conclusions are not affected by the uncertainty of velocity structure.

The tectonics of the area are shown schematically in the inset to Fig. 1 along with the bathymetry of the northern part of the Rivera Fracture Zone. A deep, steep-sided trough is flanked by ridges on both sides. The topography is generally extremely rugged. To the south-east, beyond the area shown, the trough disappears and the fracture zone continues as a single ridge. This change in character coincides with a change in strike, the topography trending more in an east–west direction.

Three immediate conclusions may be drawn from the pattern of seismicity near array 2:

(1) The general trend of epicentres is along the central trough. This suggests that transform faulting is taking place mainly inside this feature, rather than along the valley walls.

(2) There is a definite offset in the line of epicentres near the array. It is unlikely that this offset is an artefact of location errors. Location uncertainties make it impossible to draw any similar conclusions about the more distant events.

(3) A few of the events have epicentres very close to one of the capsules. This allows well-constrained source depths to be calculated. All reliable source depths were shallower than 10 km below the sea floor, suggesting 10 km as a lower limit for the thickness of the brittle zone on this area.

With array 3, we tried to cover the junction of the rise and fracture zone. There seem to be no epicentres located within the array. The epicentres shown in Fig. 1 for this array are some of the more reliable locations (that is, with the smallest travel-time residuals). We have not yet located all the events in this area, but the epicentres shown are probably a fairly good sample.

As in the central part of the fracture zone, the main trend of epicentres is along the rift. A few km from the ridge there is a second line of activity, parallel to the first. This might indicate an offset of the main transform fault, or possibly a subsidiary fault reflecting greater complexity of the faulting as the junction is approached.

The exact location of the spreading centre is uncertain, but presumably coincides with the topographic high of the rise. It seems that, as would be expected, the seismicity does not extend beyond this. We also note that there is a swarm-like cluster of events near the junction, east of the array. These results are similar to those of Reid and Macdonald[6] on the Mid-Atlantic Ridge. Since all the events located lie outside the array, little reliance can be placed on source depth determinations. It appears, however, that the depths of the nearest events are shallow, probably <5 km.

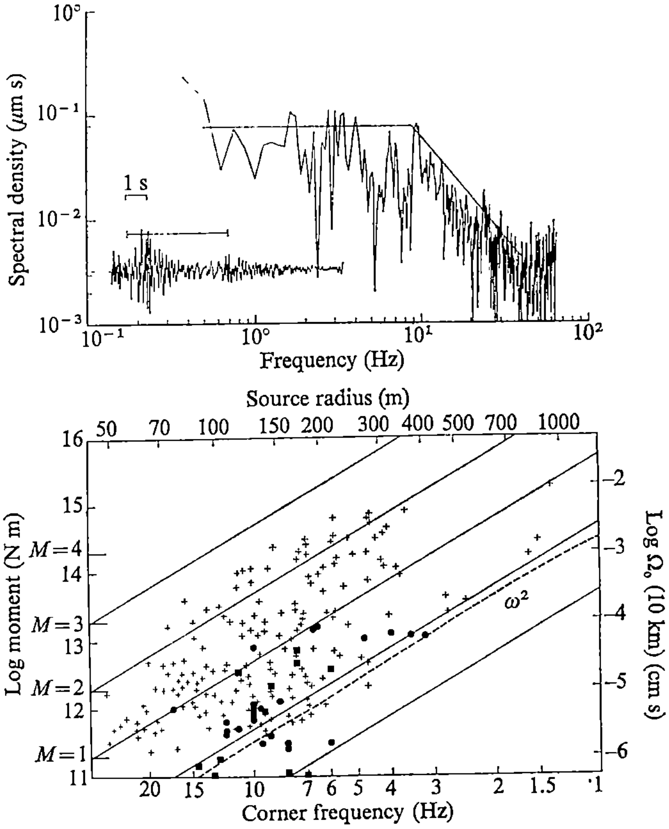

Fig. 3 Source parameters of 35 events recorded at Arrays 2 and 3. The upper portion of the figure is a ground motion spectrum of the S-wave of one of the events (Event 22). The line over the seismogram indicates the portion of the signal analysed. The source parameters from the aftershocks of the San Fernando earthquake of February 9, 1971 are shown (+) as a comparison to the oceanic data (■, Array 2; ●, Array 1). The diagonal lines give a logarithmic pressure scale, the top line gives the 10^8-Pa region (1 Pa$=10^{-5}$ bar), and each subsequent line gives a factor of 10 smaller a pressure, down to 10^4 Pa at the bottom.

S-wave spectra of 35 events of various sizes from arrays 2 and 3 have been computed. The spectra have been corrected for instrument response and an assumed Q of 250. This is a reasonable value of Q for S-waves on continental crust[7]. The moments and corner frequencies of nearby events are also relatively insensitive to the value of Q chosen. The instrument response was computed using measured seismometer and amplifier parameters. Figure 3 shows the spectrum of event 22 measured at capsule position BO 4 (Fig. 1). The rise at high frequencies is caused by the Q correction, which has the effect of dividing the background noise by a very small number. Also in Fig. 3 is a plot of the seismic moments against the corner frequencies of the 35 events studied. Although the results must be considered preliminary until more analysis is carried out, the stress drops estimated using the theory of Brune[8,9] do not reach values as high as those for aftershocks of the San Fernando earthquake of February 9, 1971, also plotted in Fig. 3 (ref. 7).

We conclude that epicentres of micro-earthquakes on the Rivera Fracture Zone indicate that the main transform fault lies inside the central trough. There is evidence that at least one offset occurs in this fault. One interpretation of this would be that this offset represents a minor spreading centre similar to, but on a smaller scale than, those in the Gulf of California. A small component of spreading on this section of the fracture zone would be consistent with the interpretation of the central trough as a rift feature. Source depths suggest a brittle zone ~10 km thick. S-wave spectra of 35 events suggest a lower upper-bound for stress drop than found for the San Fernando earthquake of February 9, 1971.

We thank the NSF for supporting this research effort. Numerous persons contributed in an important way to this project, including Dave Willoughby, Georgeanne Ray, John Orcutt, Paul Spudich, Dorothy Darling, and Captain Newbegin and the crew of the Ellen B. Scripps.

Further rubidium–strontium age and isotope evidence for the nature of the late Archaean plutonic event in West Greenland

THE gneisses of the Godthaabsfjord region of southern West Greenland have been grouped by McGregor[1] into an older and a younger set, respectively termed the Amîtsoq and Nûk gneisses. They are separated by dykes (the Ameralik dykes), metavolcanic and metasedimentary rocks (the Malene supracrustals) and stratiform meta-anorthosites. The Amîtsoq gneisses have been dated at ~3,700–3,800 Myr (refs 2–4). Pankhurst *et al.*[5] reported a Rb–Sr whole rock isochron age of 3,040±50 Myr and an initial $^{87}Sr/^{86}Sr$ ratio of 0.7026±0.0004 on a suite of Nûk gneisses from Björneöen, some 25-km northeast of Godthaab (Fig. 1). The isochron age was interpreted as the age of emplacement of the precursors of the Nûk gneisses, while the low initial ratio suggested that these precursors could not have been derived by partial or complete melting of the older Amîtsoq gneisses. Several geologists have expressed disagreement with this interpretation[6,7]. In particular, Chadwick *et al.*[7] disagreed with our conclusion that the Nûk gneisses represent essentially juvenile sialic crust formed in West Greenland ~2,800–3,000 Myr ago. We here present further evidence to support our interpretation.

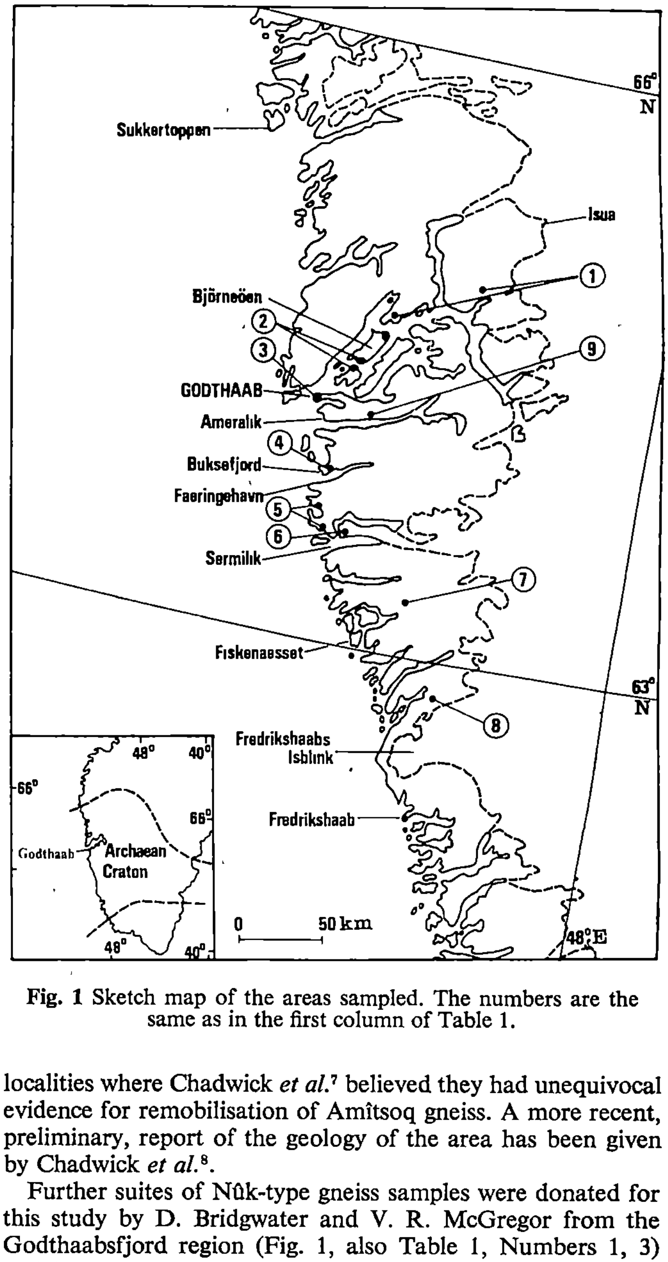

Fig. 1 Sketch map of the areas sampled. The numbers are the same as in the first column of Table 1.

A large collection of Nûk gneisses was made by us in 1973 from the area between Buksefjord and Sermilik (Fig. 1, also Table 1, Numbers 4, 5, 6). Some of these samples are from localities where Chadwick *et al.*[7] believed they had unequivocal evidence for remobilisation of Amîtsoq gneiss. A more recent, preliminary, report of the geology of the area has been given by Chadwick *et al.*[8].

Further suites of Nûk-type gneiss samples were donated for this study by D. Bridgwater and V. R. McGregor from the Godthaabsfjord region (Fig. 1, also Table 1, Numbers 1, 3) and by J. S. Myers from Fiskenaesset (Fig. 1, also Table 1, Number 7).

We summarise in Table 1 Rb–Sr whole rock isochron ages and initial $^{87}Sr/^{86}Sr$ ratios obtained on a total of 96 samples of Nûk-type gneisses grouped into different areas (Fig. 1). We also present whole rock data for the post-tectonic Qôrqut Granite (Fig. 1, also Table 1, Number 9), the last major rock-forming

Table 1 Summary of Rb–Sr age and isotope results for Nûk-type gneisses and Qôrqut granite

Area (see Fig. 1)	No. of Samples	Mean Rb (p.p.m.)	Mean Sr (p.p.m.)	R*	Age (Myr)†	Initial $^{87}Sr/^{86}Sr$	F‡

event in the Godthaabsfjord region[1]. (Individual analytical data for these 103 samples are not reported here, but may be obtained on request from the authors.) Full details of chemical and mass-spectrometric techniques have been described elsewhere[9]. Rb/Sr ratios were determined by a precise X-ray fluorescence (XRF) technique described by Pankhurst and O'Nions[10].

New analyses on the 14 samples from Björneöen reported by Pankhurst *et al.*[5] (Table 1, Number 3) yield slightly revised age and initial $^{87}Sr/^{86}Sr$ values of 2,930±70 Myr and 0.7023±0.0003, mainly from recalibration of the XRF method using USGS standard rocks[10]. These are, however, still within the error of the published values, quoted earlier. The ages reported in Table 1 for groups 1 to 7 range from 2,780 to 2,930 Myr, whilst the initial $^{87}Sr/^{86}Sr$ ratios range from 0.7015 to 0.7031. The errors within each range do not completely overlap, so that small, significant differences appear to exist, as discussed later. Nevertheless, our principal observation is that the grouping is remarkable for its overall coherence in age and initial ratio over the huge area sampled (Fig. 1).

Figure 2 is a composite Rb–Sr whole rock plot for all samples from groups 1–7 reported in Table 1. For comparison, the published values for the Amîtsoq gneisses are also plotted[2,4]. The plot demonstrates the lack of overlap between the Nûk and Amîtsoq linear arrays and also shows that both gneiss groups exhibit a similar range of Rb/Sr ratios. This is not surprising, considering the close overall petrological and geochemical similarity between the comparable variety of rock types (for example, granites, granodiorites, tonalites and diorites) which make up both the Nûk and Amîtsoq gneisses. This in itself argues against formation of the Nûk gneisses by reworking of Amîtsoq gneisses, since this would be expected to result in a general increase of Rb relative to Sr in the remobilised material.

Several samples from the Sermilik area (Table 1, Number 6) are at granulite grade, whereas all other samples in the present study are presumed to be at amphibolite grade. Clearly, metamorphic grade has had no effect on the Rb–Sr age or initial $^{87}Sr/^{86}Sr$ of the rocks. This accords with the view that the parent magmas of the Nûk gneisses were emplaced during an igneous event which was broadly contemporaneous with high-grade metamorphism and gneissification. This conclusion has been advanced specifically for the Ilivertalik granite on the south side of Sermilik, to which some of the present samples, which were all collected on the north side of Sermilik, may indeed belong, and which has yielded a U–Pb zircon age of 2,835±10 Myr (ref. 11). Moreover, the mean Rb–Sr age of ~2,850 Myr reported here for Nûk gneisses agrees within analytical error with the mean $^{207}Pb/^{206}Pb$ whole rock age of granulite facies gneisses and associated anorthosites from the Nordland–Sukkertoppen and Fiskenaesset areas, respectively north and south of Godthaab (Fig. 1)[12]. The Pb/Pb age was interpreted as the probable age of the granulite facies metamorphism, whilst the actual Pb isotope ratios suggested that the gneisses were not reworked Amîtsoq gneisses but represented an addition of crustal material from the upper mantle source regions within the period ~2,800–3,000 Myr ago.

Figure 3 shows averaged Rb–Sr growth lines for the major rock units so far analysed from West Greenland, plotted in relation to a hypothetically linear upper mantle growth line. Two groups of much younger gneisses from South Greenland ~1,700–1,800 Myr old[13], are also plotted for comparison.

Consideration of Fig. 3 supports our earlier conclusion that the Nûk gneiss precursors were not derived by partial melting and mobilisation of Amîtsoq gneisses, since the average growth lines of the latter are far too steep. By 2,850 Myr ago, the average $^{87}Sr/^{86}Sr$ ratios of Amîtsoq gneisses would have been ~0.705–0.715. This argument is strongly reinforced by the similarity in range of Rb/Sr ratios between the Nûk and Amîtsoq gneisses already noted above (Fig. 2).

We conclude that the "irrefutable" identification of Amîtsoq gneisses by Chadwick *et al.*[7,8] in the Buksefjorden–Sermilik area is contradicted by the dissimilarity of the present data with the established Rb–Sr chronology in the Godthaab region. In this connection, four whole-rock samples from just north of Sermilik, cut by amphibolite fragments considered as correlative with the Ameralik dykes, are included in Table 1, Number 6. They cannot be distinguished from the main body of data and separately yield an isochron age of 2,760±80 Myr and an initial $^{87}Sr/^{86}Sr$ ratio of 0.7020±0.0004.

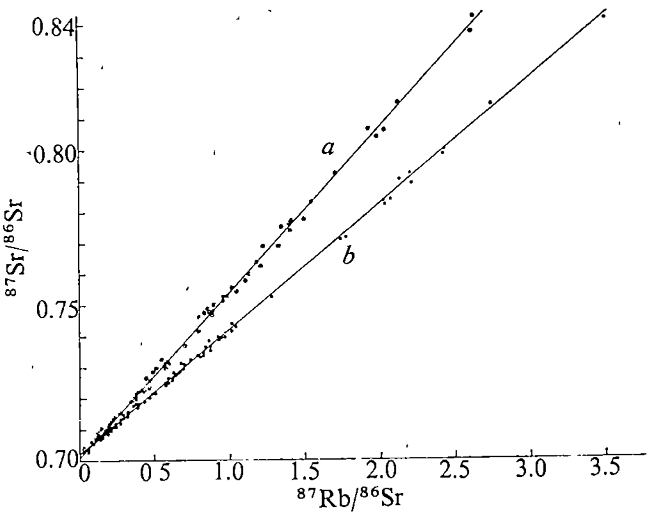

Fig. 2 Rb–Sr whole rock isochron plot for *a*, Amîtsoq gneisses[2,4], with 3,700-Myr reference line; *b*, Nûk-type gneisses, Groups 1 to 7, Table 1, with 2,850-Myr reference line. Three very high Rb/Sr points have been omitted from each line.

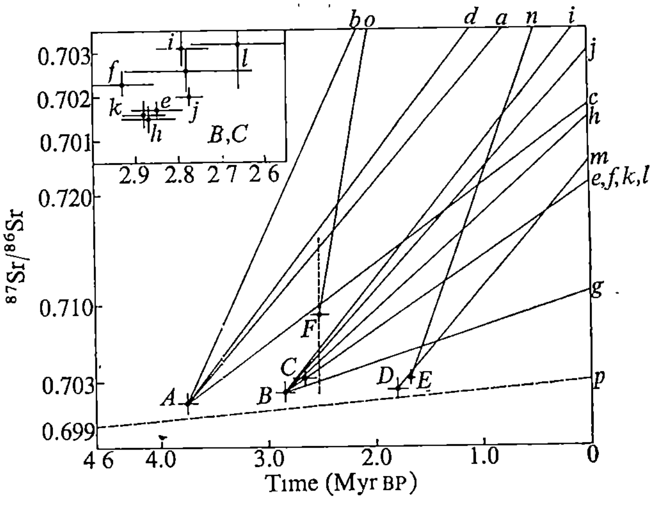
At the present time there is very little evidence for Archaean rocks with high $^{87}Sr/^{86}Sr$ ratios. Hurst *et al.*[14] report an age and initial $^{87}Sr/^{86}Sr$ ratio of 3,120±60 Myr and 0.7064±0.0012 for a group of late "Undifferentiated gneisses" from Saglek, Labrador, whilst Barton[15] has quoted a value of 0.7044±0.00010 for gneiss from Hebron, Labrador dated at ~3,600 Myr, although in the latter case we believe there has been a serious underestimation of the error. Barton quotes errors calculated by two different methods but, for no stated reason, uses the lowest error value. Little is known of the chemistry of the Saglek "Undifferentiated gneisses" and the possibility that there has been redistribution of ^{87}Sr in these rocks on the scale of sampling

Fig. 3 Average $^{87}Sr/^{86}Sr$ growth lines for: *A*, Amîtsoq gneisses[2,4] from *a*, Narssaq; *b*, Qilangarssuit; *c*, Praestefjord; *d*, Isua; *B*, Nûk-type gneisses (Table 1) from *e*, head of Godthaabsfjord; *f*, Björneoen; *g*, Godthaab; *h*, Buksefjorden; *i*, Faeringehavn; *j*, Sermilik; *k*, Majorqap qâva, Fiskenaesset; *C*, *l*, Fredrikshaab Isblink[16]; D, E, Ketilidian gneisses, South Greenland[13]; *m*, Group 1; *n*, Group 2; F, Qôrqut Granite, Ameralik. The line *p* represents a hypothetically linear upper mantle growth line. The inset is a magnification of points *B* and *C* for the Nûk-type gneisses listed in Table 1.



following a previous crustal history cannot be discounted. Such a process would mean that partial melting and intrusion of magma need not necessarily have occurred at 3,120±60 Myr ago. The only unequivocal case known to the authors in which Rb–Sr systems demonstrate "isotopic reworking" of Archaean crust is a Rb–Sr whole-rock isochron of 2,300±150 Myr with an initial $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratio of 0.7126±0.0011 for gneiss from Vesterålen, Norway[16]. Pb isotopes in the same rocks preserve an age of ~3,500 Myr, however, so that in this case it is unlikely that "isotopic reworking" involved segregation of a partial melt.

The Qôrqut granite of West Greenland (Table 1, Number 9) gives a whole-rock isochron age of 2,520±90 Myr and initial $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ of 0.709±0.007, in good agreement with a previously published mineral isochron for a related pagmatite[17]. The high Rb/Sr ratios of the analysed samples have so far precluded more precise determination of the initial $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratio and this therefore remains ambiguous in terms of its petrogenetic implications. In view of the more extreme granitic aspect of the Qôrqut granite (predominantly quartz and K-feldspar with few mafic minerals) compared to the earlier gneisses it might well be derived by remobilisation of old crustal material.

The small but statistically significant range of age and initial $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratios of the Nûk type gneisses in West Greenland (see Table 1 and inset, Fig. 3) may genuinely reflect small differences in the age of emplacement and pre-history of the parent magmas. We believe that a plutonic episode of such magnitude comprises complex, multistage processes lasting for perhaps 100–200 Myr. It is, however, also possible that the gneisses have variously suffered partial redistribution of radiogenic ^{87}Sr during the course of this episode, so that it is not possible to be absolutely sure that each of the isochrons in Table 1 records the specific age of emplacement of any one suite of cogenetic igneous rocks. The fact that none of the best fit lines are perfect isochrons (for which $F \leqslant 1$ in Table 1), and that there is a faint suggestion of inverse correlation between isochron age and initial $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratio within the 2,900–2,650-Myr interval, emphasises this doubt, although the latter observation is rather heavily biased by the results of Pidgeon and Hopgood[18] from much further south at Frederikshaabs Isblink (Fig. 1, also Table 1, Number 8).

Our major conclusion remains that the igneous precursors of the Nûk gneisses throughout the area sampled represent a massive addition of new calc-alkaline material to the Archaean continental crust of West Greenland. These magmas separated from a low Rb/Sr source region, such as upper mantle, not more than 200 or 300 Myr at the most before the measured isochron ages of Table 1. Geochemical differentiation, magmatism and metamorphism all occurred during the same major plutonic episode[19,20]. There is as yet no isotopic evidence for the involvement of Amîtsoq gneisses in the formation of the Nûk gneiss precursors.

We thank D. Bridgwater, V. R. McGregor, J. S. Myers for providing samples; B. Chadwick, K. Coe, A. D. Gibbs, M. R. Sharpe, P. R. A. Wells for help in the field; all the above for stimulating discussion; R. Goodwin and M. Humm for skilled technical assistance; the NERC and the Geological Survey of Greenland for support.

Characterisation of monounsaturated fatty acids from an estuarine sediment

PREVIOUS investigations of fatty acids in marine sediments hav primarily been concerned with the concentrations of the individual acids rather than their chemical configuration[1–4]. Brown and Swidler[5] have demonstrated the ability of clay to catalyse the conversion of oleic acid (18:1Δ^9 *cis*) to elaidic acid (18:1Δ^9 *trans*) accompanied by extensive rearrangement of the double bond position. (18:1 = normal carbon chain length: number of double bonds). As most biologically produced olefinic acids are believed to be in the *cis* configuration, diagenetic changes in the sediment may alter the *cis* isomers to the more stable *trans* isomers, as well as cause migration of the double bond. Consequently, investigations of the monounsaturated fatty acid *cis*/*trans* ratio and position of the double bonds, with depth in the sediment, may yield significant information on diagenetic pathways of these acids. We have determined the presence of small amounts of palmitelaidic acid (16:1Δ^9 *trans*) and elaidic acid (18:1Δ^9 *trans*), as well as other positional isomers of these trans acids, in a Recent estuarine sediment. In addition, we have also confirmed that the major monounsaturated fatty acids are palmitoleic acid (16:1Δ^9 *cis*) and oleic acid (18:1Δ^9 *cis*). We give here the methods for isolating these acids and confirming their structures, and their geochemical significance is discussed.

The general collection and analytical procedures have previously been reported in detail[1–3]. Surface sediment (upper 8–10 cm) was collected from station D in Narragansett Bay, Rhode Island[2]. The sediment was saponified (under reflux) for 2 h using 2:1 (*v*/*v*) 0.5 *N* KOH in 90% methanol–benzene, filtered through a Whatman No. 1 filter, and the filtrate transferred to a separatory funnel. After addition of distilled water to give two phases, the non-saponifiable fraction was removed and backwashed with *p*H 10 distilled water. The resulting aqueous phase and the initial saponifiable fraction were then both acidified to *p*H 2 and extracted three times with petroleum ether. The combined ether phases were evaporated to near dryness at room temperature under reduced pressure using a rotary evaporator. Subsamples were then taken for each analysis.

To subsamples I and II were added 17:1Δ^{10} *cis* or 17:1Δ^{10} *trans* fatty acid internal standards. Each subsample was then methylated using BF_3–methanol and the methyl esters isolated by thin-layer chromatography (TLC)[1]. The methyl esters were further separated on $AgNO_3$–TLC to isolate both *cis* and *trans* monounsaturated esters[6,7].

The *cis* and *trans* fractions were individually analysed by flame ionisation gas–liquid chromatography (GLC) using a Hewlett-Packard model 5750 gas chromatograph. The resulting chromatogram for the *trans* methyl esters is shown in Fig. 1. The proper configurational assignments were made on the basis of relative retention times and coinjection with authentic standards on a stainless steel column (6m × 2.2mm inside diameter) containing GP-15% SP-2340 on 100/120 Chromosorb P, AW-DMCS (Supelco), resolution[8] = 0.83 for 16:1Δ^9 *cis*

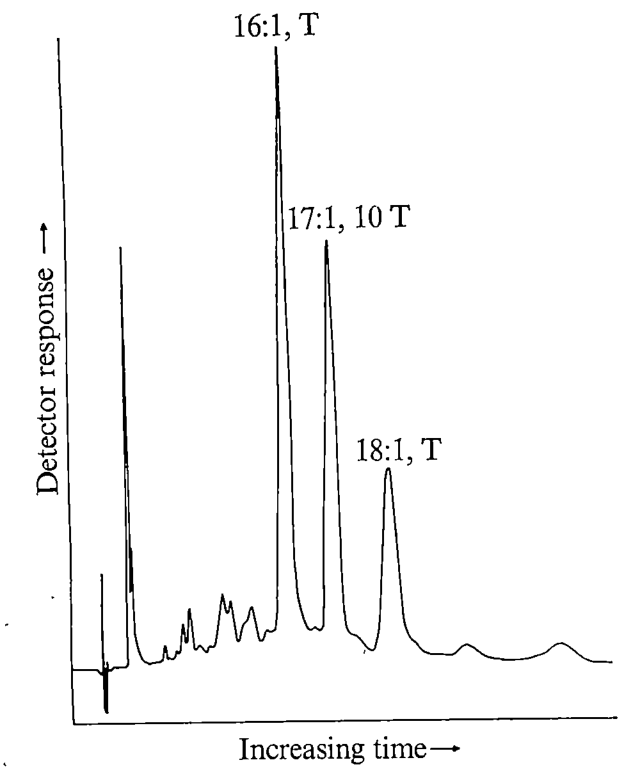

Fig. 1 Gas chromatogram of 16:1 and 18:1 *trans* methyl esters, in presence of 17:1Δ^{10} *trans* methyl ester internal standard, recovered from station D surface sediment.

and *trans*. Each sample was also hydrogenated and co-injected with standard saturated esters

To determine the quantitative amount of each acid, the areas of the peaks of the naturally occurring acids (before and after hydrogenation) were compared with the areas of the internal standard. (No natural 17:1 *cis* or *trans* was detected in the sediments.) The GLC analysis of I and II indicated the quantities of fatty acids in the sediment to be as follows (μg acid per g dry weight of sediment): for 16:1 *cis*, 17.1$\mu g\ g^{-1}$, for 16:1 *trans*, 1.7 $\mu g\ g^{-1}$, for 18:1 *cis*, 9.6 $\mu g\ g^{-1}$, and for 18:1 *trans*, 0.8 $\mu g\ g^{-1}$. Analytical uncertainty was found to be ± 10% or less. Thus in both cases, the *cis* isomer accounted for ~ 92% and the trans isomer ~ 8% of the total 16:1 and 18:1 acids.

To investigate the possibility of the *trans* isomer being generated from the *cis* isomer during the saponification, methylation, or TLC procedures, a series of blanks was carried through the entire analysis. Each blank consisted of a pre-extracted sediment plus various combinations of 16:1, 17:1 and 18:1 *cis* standard acids. No *trans* acids were generated during this procedure

The configurational assignments were verified by infrared spectroscopy and combined gas chromatography–mass spectrometry (GC–MS) analyses. Two separate subsamples, III and IV, were processed by the above methods without internal standards. Portions of the purified *cis* and *trans* methyl esters were each analysed by GC–MS (Finnigan 1015C). The resulting GC–MS spectra for these esters were compared with spectra for authentic standards and agreed well in all cases. The GC–MS spectrum for the *trans* methyl ester of the eighteen carbon fatty acid is shown in Fig. 2. This spectrum shows the molecular ion peak at *m/e* 296 (M^+). Some characteristic fragmentation peaks are *m/e* 265 (M^+ −31), *m/e* 264 (M^+ −32), *m/e* 222 (M^+ −74), and *m/e* 74 (McLafferty rearrangement)[9,10].

Separate portions of III and IV were analysed by infrared spectroscopy (Perkin Elmer model 521) and compared with authentic standard infrared spectra. The infrared spectrum of the *trans* methyl esters is presented in Fig. 3 and shows the characteristic *trans* absorption at 965 cm^{-1} (10.3 μm). The infrared spectrum of the *cis* methyl esters showed both the absence of the *trans* band at 965 cm^{-1} and the presence of a stronger absorption in the region of 3,015 cm^{-1} (3.32 μm). The infrared and GC–MS spectra together with the GLC analyses confirm the presence of both 16:1 and 18.1 *cis* and *trans* acids.

Portions of III and IV were oxidised using $KMnO_4$ in a modification of Downing and Greene's[11] procedure to determine the position of the double bond. The sixteen and eighteen carbon *cis* oxidation products yielded primarily the C_7 and C_9 methyl esters and the C_9 dimethyl ester, indicating the double bond to be predominantly in the 9–10 position for both fatty acids. The ratios of the dimethyl esters recovered indicate that ~ 62% of the double bonds in the *cis* isomers are in the 9–10 position, 19% are in the 11–12 position, and 19% are in other possible positions from C_5 to C_8, and C_{10}.

Analysis of the sixteen and eighteen carbon *trans* oxidation products again yielded primarily the C_9 dimethyl ester and the C_7 and C_9 methyl esters, indicating the double bonds in both *trans* isomers to be predominantly in the 9–10 position. The ratios of the dimethyl esters recovered from the oxidation of the *trans* isomers indicate that ~ 70% of the double bonds are in the 9–10 position, 23% are in the 11–12 position, and 7% are in other positions as above. Within the accuracy of the method, there is no significant difference between the positions of the double bonds in the *cis* and *trans* isomers.

The three most common monounsaturated fatty acids found in organisms are oleic acid, palmitoleic acid, and vaccenic acid (18:1Δ^{11} *cis*)[12]. It appears that the major monounsaturated acids present in the examined surface sediment are the 16:1Δ^9, 18:1Δ^9 and 18:1Δ^{11}. These are present as ~ 92% in the *cis* configuration and 8% in the *trans* configuration. Since the double bonds are primarily in two positions, the 9–10 and 11–12 positions, this would seem to indicate that the *cis* isomers present in this surface sediment result from a direct biological input. The *trans* isomers result from either a direct input or from microbial modification of the *cis* isomers in the sediments. The *trans* isomers apparently do not result from the clay catalysed isomerisation of the *cis* isomer. According to Brown and Swidler[5] the clay catalysed isomerisation of the *cis* octadecenoic acid yields a mixture of the *trans* isomers with the double bond ranging from the 2–17 positions, and the 9–10 *trans* isomer making up only 23% of the total.

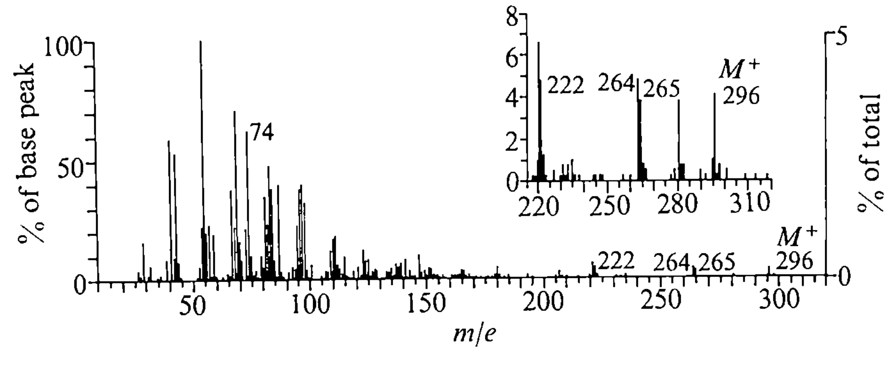

Fig. 2 GC–MS spectrum of 18:1 *trans* methyl ester recovered from station D surface sediment, no internal standard added (*m/e* 220–310 expanded in upper right).

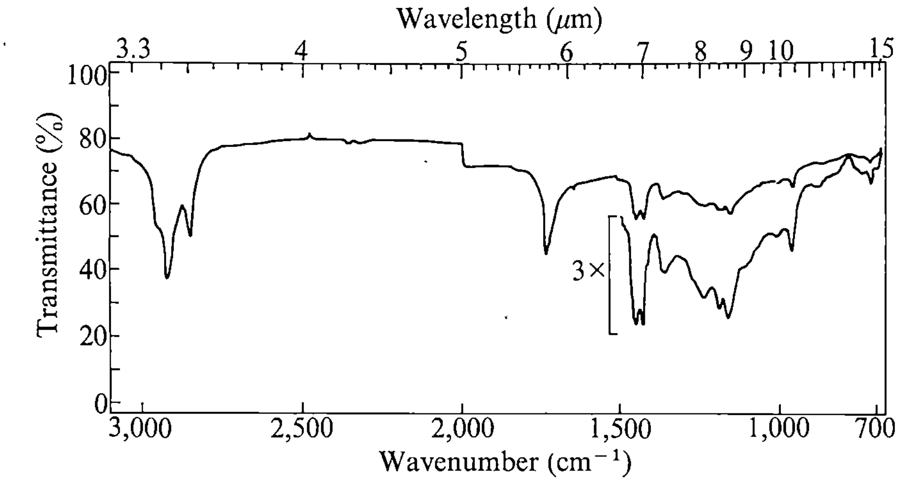

Fig. 3 Infrared spectrum of 16:1 and 18:1 *trans* methyl esters recovered from station D surface sediment; no internal standard added.

Although the absolute quantities of the monounsaturated fatty acids normally decrease with depth in the sediment[2], secondary effects may result from clay catalysis. As depth increases, the clay catalysed conversion of the *cis* to *trans* isomers may occur until an equilibrium mixture of *cis* and *trans* results (for the 18:1 acid, the equilibrium mixture is ~ 33% *cis*, 67% *trans*[5,13]). As the *cis* isomer is isomerised to the *trans* isomer, it may also result in a migration of the double bond throughout the molecule. Thus with increasing depth in the sediments, there exist two potential biogeochemical markers based on monounsaturated fatty acids, the ratio of *cis*/*trans* and the position of the double bond.

This work was supported by the National Sea Grant Program. We thank Dr Chris Brown for the infrared analyses and Dr Peter Rogerson and Curt Norwood for the GC–MS analyses.

Evidence for short term atmospheric ^{14}C variations about 4,000 yr BP

IT is well established from radiocarbon measurement of tree rings of known age that the natural ^{14}C level in the Earth's atmosphere has undergone a gradual change of more than 10% over the past 7,000 yr (see, for example, ref. 1). During this time there have probably also been periods of irregular fluctuation spanning a few hundred years (the so-called Suess 'wiggles'[2]). The existence, in addition to these effects, of substantial shorter term (~ 10–20 yr) variations possibly correlated with solar activity is less certain. Farmer and Baxter (ref. 3) found ^{14}C variations of up to 3% in 10 yr (equivalent to an age error of ±120 yr) over a consecutive sequence of 37 single tree rings taken from mid-nineteenth century wood grown in the Forest of Dean, England; but comparative measurements they made of twentieth century New Zealand wood were inconclusive. Twentieth century wood from Trondheim, Norway, showed a possible 0.6% variation[4], and twentieth century North American wood showed about 0.3% (ref. 5).

We present here the results of radiocarbon measurements of Red Deer antlers obtained from recent excavations of Neolithic flint mines at Grime's Graves, Norfolk. When taken with the archaeological evidence these results indicate that short term variations similar to those found in wood from the Forest of Dean may also have occurred at an earlier period.

During the later Neolithic in Britain (~2,000 yr b.c. on the basis of radiocarbon dating) flint was mined on a large scale at Grime's Graves. Shafts, typically about 13 m deep and 3–5 m in diameter, were sunk through superficial deposits into the Upper Cretaceous Middle Chalk to reach a more or less continuous 20-cm layer of tabular flint. At the base of the shafts 4–7 horizontal galleries ~ 75 cm–1.5 m high, 3–5 m wide and 5–10 m in length were cut. The antlers that were used for the radiocarbon measurements were used by the miners as levers or 'picks' (Fig. 1) and were found in large numbers amongst the chalk rubble filling the galleries (chalk waste from new galleries

*Dates, expressed in yr b c. (5,570-yr half life), have been corrected for isotopic fractionation (δ^{13}C) relative to the PDB standard. The s.d. was derived from about 15 replicate measurements of each sample (totalling > 10^4 counts).

†Δ values[10] have been calculated from a mean age of 1,950 yr b.c. See Fig. 2 for the general distribution of these samples within the galleries of pit 15.

was back filled into those from which flint had already been extracted, sealing discarded antlers in position). The antlers were preserved in an environment entirely free from contamination by more recent organic material. To eliminate the possibility of exchange with more ancient carbon only the protein matrix remaining after complete demineralisation with dilute hydrochloric acid was used for the radiocarbon measurements.

Table 1 lists the results of radiocarbon measurements (using the liquid scintillation counting method[6]) on antlers from one of the excavated pit groups (pit 15) originally made to obtain a series of archaeological dates for the mining activity. The measured ages are distributed over a range of some 300 radiocarbon years, with a mean value of 1,950 yr b.c. and a standard deviation for the distribution as a whole of 79 yr. This value is considerably larger than the average standard deviation for the individual age estimates (47 yr). Thus, it is very unlikely (at the 99% confidence level) that each of the samples measured has the same ^{14}C concentration. The data also show a tendency to cluster into an early group (older than 1,990 yr b.c.) and a late group (younger than 1,940 yr b.c.; with one possible outlier at 1,786 yr b.c.) which is related to the find positions of the antlers in the galleries (see Fig. 2). If that were because pit 15 was worked at separate periods the time spread needed to satisfy the data would be of the order of 120 yr, whereas all the available evidence indicates that this pit was actually worked for a single short period which probably did not exceed 10 yr, and may have been much less. One estimate[7] has suggested that one pit could have been fully exploited in six months. On this basis a reasonable estimate for the exploitation of the entire deep mining area at Grime's Graves (some 400 pits) would be less than 200 yr as groups of adjacent shafts were most probably open contemporaneously.

In support of the idea of rapid exploitation, excavated shafts show little trace of weathering implying that they were open for a short time and were then rapidly infilled artificially with the massive quantities of spoil resulting from the digging of new shafts nearby. Comparison with weathering evidence obtained from studies of artificial earthworks[8,9] suggests a maximum of 5–10 yr as a cautious overestimate of the length of time for which a shaft was open. Taken altogether this means that the galleries of any one excavated pit complex, whether they radiated from the central pit or from the shafts surrounding it, would most probably all have been cut within a decade at most and the abandoned antlers sealed in place within that time.

Therefore, we must assume that the variation found is attributable to an effect other than real age differences, and is inherent either in the measurement procedures used in our laboratory or in the samples themselves. Taking the first alternative, the samples were measured in small groups interspersed with measurements of other totally unrelated samples, over a period during which our well tried monitoring procedures revealed no abnormalities in the behaviour of the counting system, and we can see no reason to doubt the reliability of the results.

We therefore propose that the variations are most probably attributable to an effect inherent in the samples. Antlers grow and are shed each season, and since they would not be suitable for use as tools unless collected when freshly shed, those accumulated in any one pit complex must form a physical assemblage of short-lived material of a restricted age range. From the number of antlers found (over 70 in pit 15) it is evident also that they were regarded as expendable and were casually discarded when blunted or broken. It is reasonable to assume, therefore, that the ^{14}C activity of the antlers found in a particular gallery closely reflects the atmospheric activity in the summer before that gallery was mined. It is worth noting here that the antlers in the lower left hand corner of Fig. 2 all had a similar activity. The range of ^{14}C activity observed in the antlers from pit 15 as a whole is much larger than can be accounted for unless there were marked year-to-year changes in atmospheric ^{14}C activity. Our results would require a minimum atmospheric ^{14}C variation of the order of 2% over a period of 10 yr or less. In the light of previous findings (refs 3–5) that is not implausible, although the exact cause of the variations remains obscure.

Fig. 1 Deer antler pick.

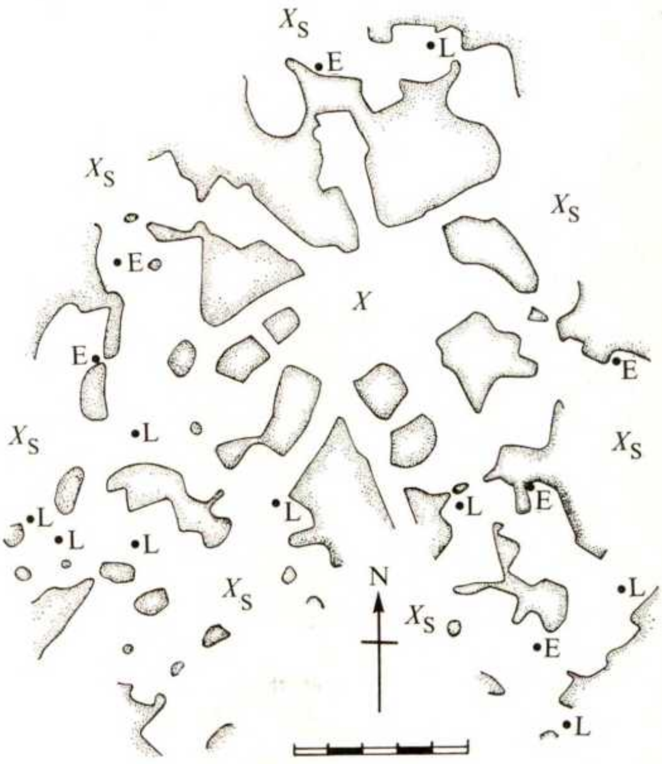

Fig. 2 Diagrammatic plan of the galleries of pit 15 at Grime's Graves, showing original position of each sample. E, L, indicate whether the radiocarbon age estimate obtained falls early or late in the sequence (see text and Table 1). ×, Shaft of pit 15; x_S, approximate positions of surrounding shafts. Scale in metres.

We recognise that our interpretation of these measurements must remain an hypothesis at present but the alternative explanation that the pit was in use over a 120-yr period is contrary to the archaeological evidence. Finally, the stable isotope values (δ^{13}C, Table 1) do not support the possibility that the observed ^{14}C variations are attributable to dietary factors affecting the deer. Clearly, more work is necessary, and we hope to substantiate our findings by excavating further material from a different pit at Grime's Graves during the coming season.

Our preliminary conclusion is that, although differing fundamentally from tree rings (where either the absolute or relative age is known initially) the special circumstances of the physical association of the antlers provides direct corroborative evidence for the kind of short term ^{14}C variation previously observed in recent tree rings.

More generally, we suggest that although knowledge of the ultimate resolution that radiocarbon dating can achieve is still

Lead isotope studies of metal sources for ancient Nigerian 'bronzes'

INTEREST in the composition of Nigerian 'bronzes' began in 1897, the year of the British punitive expedition to the city of Benin, when Nigerian metal art was brought to the attention of the western world as a spoil of war. In spite of the dissemination of much of this art to museums, and the subsequent focus of research, important questions concerning the chronological ordering of the pieces and relationships among forms and iconographies remain unanswered.

Elemental analyses of a number of these 'bronzes' (see refs 1–7) reveal that they are actually copper alloys with varying amounts of zinc, lead, tin and other metals. Though patterns of elemental composition can be discerned, statistically well defined measurements are not easily accomplished[8] and interpretation of the patterns is difficult.

Since the lead content of most pieces is appreciable ($\geq 1\%$–12%; see Table 1), enough, in fact, to suggest that its addition may have been intentional, we have conducted lead isotope analyses. As each lead ore deposit has a set of characteristic ratios among the isotopes, source distinctions can often be clearly drawn. Small samples in the tens of milligram range have been collected by scraping from approximately 180 'bronzes' from various museums in Nigeria, Europe and the United States. Analyses (see ref. 9) to determine lead isotope ratios have been made of samples from 17 of the more important 'bronzes' (Table 1 and Fig. 1). Only two of the three independent ratios are illustrated in Fig. 1, but all three ratios have been examined with interactive, three-dimensional computer graphics, and compared with isotopic ratios from known lead sources.

The lower panel of Fig. 1 shows a surprisingly strong clustering of the isotopic ratios. All of the Benin pieces have virtually the same isotopic ratios, in spite of a speculated range of production dates spanning approximately from the fifteenth to the nineteenth century. In this same cluster, which we identify as Benin +, pieces identified as 'Owo' (Table 1, *B*), 'Udo' (*J*) and 'Lower Niger' (*A*, *G*, *H* and *M*) are also found. In contrast, the two pieces excavated at Igbo–Ukwu (*P* and *Q*), for which there is evidence of a ninth century date[2] (which has, however, been contested[10]), show quite different values for the isotopic ratios. The single piece studied from Ife(*O*), considered by some[11] to be a cultural forerunner of Benin (and identified in Benin oral tradition as the source of Benin metal working knowledge[12]) has intermediate values for the two isotopic ratios shown in Fig. 1. One piece, the 'Lower Niger' ram's head pectoral (*H*), has two ratios falling in the Benin + cluster and one ratio resembling the Igbo–Ukwu pieces.

Three major conclusions can be drawn. First, the similarity of the isotopic ratios for the Benin + group provides evidence for a single source of lead for the entire time span and variety of locations represented by that group. (The 'Lower Niger' pectoral is a possible exception.) It is unlikely that lead from the Benin + group is a mixture from isotopically different sources since the mixing ratio would have to be nearly constant for all the pieces.

Second, support is lent to the hypothesis that Igbo–Ukwu, Ife and Benin were indeed separate traditions.

Third, the great majority of lead deposits in use today are ruled out as sources, as will be discussed elsewhere.

Several questions are raised, however:

- Why is there such a constancy of lead source throughout the Benin + group in the light of shifting trade patterns within Africa and with Europe.
- What is the nature of the apparent link between the makers of the Benin, 'Udo', 'Owo' and the 'Lower Niger' pieces?

- Could the Ife piece be a mixture of the sources used by the Igbo–Ukwu culture which may have preceded it, and the Benin culture which may have followed it?
- What were the actual sources of the lead and the patterns of its trade? Were the sources local (Nigerian) or were the raw materials brought from elsewhere in Africa (perhaps on trans-Saharan trade routes) or did they arrive from Europe?

Work is continuing to attempt to answer some of these questions.

Parental investment, mate desertion and a fallacy

TRIVERS[1] defines parental investment as "any investment by the parent in an individual offspring that increases the offspring's chance of surviving . . . at the cost of the parent's ability to invest in other offspring". He has cleverly used this definition to elucidate many outstanding problems in social ethology[1–3]. But one of his most appealing usages of it is fallacious.

He states[1]: "At any point in time the individual whose cumulative investment is exceeded by his partner's is theoretically tempted to desert". The context is that of a mated pair of birds, cooperating in the rearing of young. At various times during incubation the female has invested more in the offspring than the male, and the male is said to be tempted to desert. At other times the male's cumulative investment is higher, and the female is then said to be tempted to desert.

If true, this idea would have interesting consequences. A female, in danger of being deserted after copulation, might force a male to invest heavily in her offspring before they are conceived. The price of copulation might be a well built nest and plenty of courtship feeding. Even useless 'labours of love' might be imposed as a means of increasing the male's investment before copulation, and therefore of reducing his temptation to desert afterwards. The theory also neatly uses the difference in gamete size to explain why females make better parents than males. As Trivers says[1]: ". . . her initial very great investment commits her to additional investment more than the male's initial slight investment commits him".

The idea has been influential[4], and it appeals to economic intuition. A government which has invested heavily in, for example, a supersonic airliner, is understandably reluctant to abandon it, even when sober judgment of future prospects suggests that it should do so. Similarly, a popular argument against American withdrawal from the Vietnam war was a retrospective one: "We cannot allow those boys to have died in vain". Intuition says that previous investment commits one to future investment.

The fallacy can be demonstrated by analogy. Suppose a female has an orphaned baby brother, the same age as her own son. She has only enough food to keep one of the two infants alive. Which should she prefer? Intuition points to the son, but this is not necessarily correct. There are no genetic grounds for preferring either infant: the mother's relatedness[5] to both is the same, 0.5. A naive application of parental investment theory predicts that the female should prefer the son on the grounds that she has already invested heavily in him: she should not let all her earlier investment go to waste by preferring the brother, in whom she has invested nothing.

This argument is wrong for it misunderstands why quantity of previous investment is important. A child in whom more has already been invested should be preferred only because he is going to need less investment in the future. This means he can be fledged (or weaned) sooner, and the parent will therefore be free to invest in new children sooner. Our hypothetical female should prefer whichever of the two children has already had most invested in him, regardless of who did the investing, because his future life can be bought more cheaply.

We now return to the original quotation from Trivers. The father and mother have an equal genetic stake in each offspring. Either parent's reluctance to desert at any moment should be related to the quantity of investment still needed to bring the offspring to maturity. This quantity will be negatively related to the amount that has already been invested: it does not matter who did that investing. Trivers almost acknowledges this in another part of the same paper[1], when he suggests that it may pay either partner, even the one who has so far invested most, to desert. This forcible closure of options puts the deserted partner in "a cruel bind". But Trivers's characterisation of the cruel bind is misleading: ". . . the deserted partner . . . has invested so much that he loses considerably if he also deserts the young, even though, which should make no difference to him, the partner would lose even more". The true nature of the cruel bind is this. Regardless of who did the previous investing, the young have had so much poured into them that either partner alone has a good chance of rearing them. To desert after one's partner has deserted is to condemn the young to death; to desert first merely condemns one's partner to make the difficult decision. Genes for deserting first are favoured by natural selection, precisely because genes for deserting second are not. But in either case, the important quantity influencing the decision is quantity of future investment which will be required.

It is of course true that previous investment by a particular parent is relevant to how much he or she can invest in the future: this is the basis of Trivers's definition. But for each particular parent this is a lifetime's calculation: the amount invested in the current offspring is only a small part. There is thus no justification, other than sheer coincidence, for Trivers[1] to draw the cumulative investment curves of his male and female with the same starting baseline. A parent should value the life of a particular child as a function of the proportion that this child represents of his total future reproductive prospects. These future prospects will be negatively correlated with the total amount he has invested in his lifetime, but only negligibly with the amount he has invested in the current particular child.

Does the theory that female coyness might evolve as a means of forcing males to invest early, thereby reducing their temptation to desert later, survive our objection to its parent assumption? This depends on how the majority of females in the population behave. If the majority play the same coy game, desertion tactics will not pay a male: he commits himself to a period of prolonged and costly courtship with a new female before she will let him copulate. If conditions are such that it would pay females to renounce coy tactics, however, the optimal strategy for a male could well be different. This is one of those cases of conflict of interest where the best strategy depends on what others are doing. We therefore suggest that the appropriate conceptual tool is Maynard Smith's[6–8] "evolutionarily stable strategy" (ESS). The contest is "asymmetric"[8], the basis of the asymmetry being sex. We seek a stable combination of male and female strategies, for example, a ratio of 'coy' to 'fast' females which is stable against an equally stable ratio of 'faithful' to 'philanderer' males. Preliminary analysis[9] suggests that there are conditions in which a stable equilibrium, consisting largely of coy females and faithful males, could evolve. More work is required (J. Maynard Smith, unpublished), but the point we make is that these are the lines along which the thinking must be. We must not simply assume that the partner who has invested least in the current offspring is the one most tempted to desert.

The other suggested consequence of Trivers's theory which we have already mentioned was that the female's high initial investment commits her to continued high investment: thus viviparity, milk-secretion, highly developed maternal care, and so on. Once again, the idea is wrongly expressed. A female is 'committed' to future investment in a child, not because of how much she has already invested in that child, but because of the cost of finishing the task, in relation to how much she would have to invest in order to bring a new child up to the same age.

In any case, the idea of past commitments leading to future commitments had difficulties in explaining the high incidence of paternal care among teleost fish[10]. Instances among birds and mammals where the father plays the main parental role are extremely rare; in the teleosts they are commonplace. Why the difference? The following theory makes use of Trivers's "cruel bind" idea, referred to earlier.

Gametes dry up in air, so this has forced terrestrial animals to copulate rather than practise external fertilisation as many fish do. After copulation, the female is left physically in possession of the zygote and while it is still in her body she cannot desert it, but the male can. However fast she lays it, the male is still offered the first opportunity to desert, thereby closing the female's options and forcing her into Trivers's cruel bind. For the reasons already discussed, this tends to lead to the evolution of maternal care.

Fish are not similarly obliged to copulate since there is no danger of their gametes drying up. In such externally fertilising species there is no automatic sense in which the female is left in possession, allowing the male to make his escape. Either sex might thus use the quick-desertion strategy. But there is a possible reason why the male might be more vulnerable to being left 'holding the baby'. Whichever partner spawns first is likely to be one jump ahead, but there is danger in spawning too early; the partner may not be ready. Sperm being lighter than eggs, tend to diffuse faster and so males have more to lose from premature spawning than females. Females can therefore afford to spawn earlier than males, putting them in a strong position to leave the male in possession of the newly conceived zygotes, forcing him into Trivers's cruel bind. This explains the widespread evolution of paternal care in fish. A comparative analysis of the incidence among teleosts[10] of external fertilisation against intromission, in relation to paternal against maternal care, might be rewarding.

In conclusion, a parent 'deciding' whether to desert a child should ask the following questions. How closely related[5] is this child to me? How likely is it to survive if I do, and if I do not, desert it? What proportion of my total future reproductive potential does this child represent? How much would it cost me to make a new child equivalent to this one? The parent should ignore its own previous investment in the particular child, except in so far as it affects the answers to these questions. Trivers is largely right, but partly for the wrong reasons.

We thank Dr. Robert L. Trivers for accepting our criticism and encouraging us to publish it.

Nitrate reductase as a possible predictive test of crop yield

NITROGEN supply is one of the key factors affecting the quality and quantity of crops. The amount of nitrogen fertiliser used is increasing year by year; on a worldwide basis we now use seven times the total fertiliser used in 1939 (ref. 1). In many developed countries the use of excess nitrogenous fertiliser is already causing environmental disturbance, especially in inland rivers and lakes, and represents a potential danger to drinking water supplies. By contrast, in much of the world crops are grown in conditions of nitrogen deficiency. Lacking in each situation is the availability of a reliable method for determining the amount of nitrogenous fertiliser, if any, which should be applied for optimal yield with minimum cost and environmental side effect, or for maximum use of limited resources. We have found that early season assays of nitrate reductase provide such a method.

Usually, whatever the source of nitrogen fertiliser, soil conditions ensure that nitrogen enters the plant predominantly as nitrate. The first and rate limiting step in nitrate utilisation is catalysed by the inducible enzyme, nitrate reductase[2] and Hageman's group in Illinois have demonstrated a correlation between nitrogen supply, nitrate reductase activity integrated throughout the year and grain yield in wheat[3] and maize[4] In these experiments, which were conducted in suboptimal nitrogen conditions, addition of further nitrogen, especially during the early part of the growing season, led to increases in nitrate reductase activity and in final grain yield.

We have examined the possibility of using nitrate reductase assays, early in the development of the crop, as a predictor of ultimate grain yield. In the first series of experiments wheat plants (Hope/Chinese Spring substitution line 7B) were grown in sand culture in controlled conditions in growth rooms, at a number of defined nitrate levels. Nitrate reductase activity in the uppermost fully expanded leaf (which was found to have the highest nitrate reductase activity (R. Hallam and G. C. Blackwood, unpublished results)) was measured weekly *in vitro* and the effect of nitrate concentration on nitrate reductase activity was compared with the effect on the final yield. The data are shown in Fig. 1. There is a good correlation between nitrate reductase and yield ($r = +0.90$, $n = 7$) at the earliest date of measurement, except at high (50 mM) nitrate concentrations. Similarly, there was a good correlation between grain yield and grain protein ($r = +0.969$, $n = 8$) indicating that increasing nitrogen supply had no effect on the protein content of the grain. Furthermore, there were no significant changes in amino acid composition. Thus early nitrate reductase activity provides a good estimate of ultimate grain yield.

The critical test of a predictive assay is its successful use on crops growing in the field To be sure of nitrogen deficient conditions for such a test, experiments were carried out (in collaboration with Dr. A. E. M. Hood of ICI's Jealott's Hill Research Station) on long standing nitrogen deficient plots at West Isley, Berkshire. Plots were treated with 0, 75, 112 or 150 kg ha^{-1} of nitrogen and measurements of nitrate reductase made early, in the middle and late in the growing season. The crop was spring barley var. Julia As before, samples for assay consisted of the uppermost fully expanded leaves and these were collected in the morning and stored at ambient temperature for several hours before nitrate reductase was determined by an *in vivo* assay in the laboratory, later in the day. Storage of intact leaves in this way did not significantly alter the enzyme activity. This is important if the test is to be of any practical use.

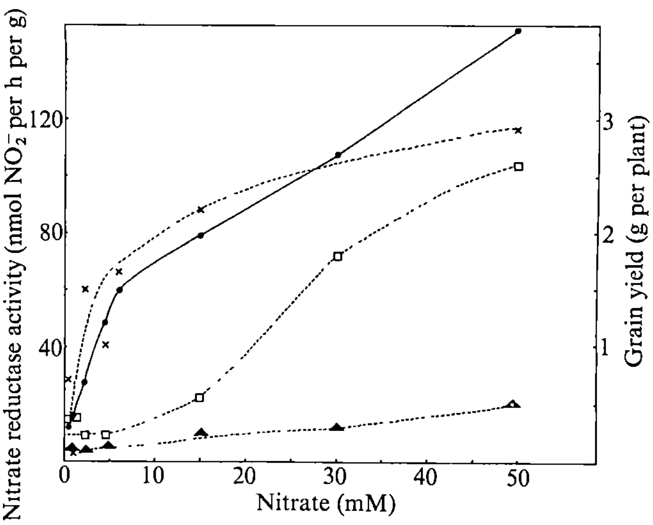

Fig. 1 Nitrate reductase activity as related to nitrate concentration in wheat (*Triticum aestivum* Hope/Chinese Spring, substitution line 7B). The enzyme was extracted from the first fully expanded leaf and assayed according to Filner[7] (×, 2 weeks; □, 3 weeks; ▲, 4 weeks after sowing). For comparison the final grain weight per plant is shown (●). Plants were grown in sand culture on Long Ashton growth medium[9] adjusted to give the desired NO_3^- concentration while maintaining constant ionic strength. Day length was 16 h; temperature 25/17 °C and light intensity 35 W m^{-2}.

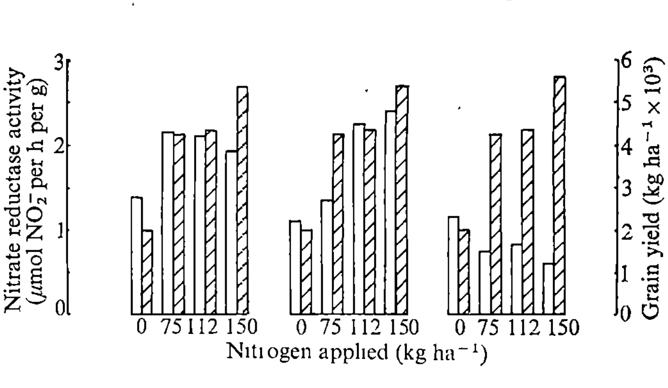
The activities of nitrate reductase at the three times of measurements are compared with the final yield in Fig. 2. The data show that, on the earliest date of estimation (3–4 leaf stage), less than maximal nitrate reductase activity is a reliable predictor of suboptimal yield. This is in agreement with the data obtained in the growth room. Amino acid composition was unaffected by the treatments. Once again, there is an increase in yield obtainable at nitrogen levels in excess of those required for maximal nitrate reductase induction. As with the growth room experiments, however, the increase in yield at these high nitrogen levels is far less in relation to added nitrogen than that obtained at lower levels where yield is correlated with nitrate reductase activity.

Although the measurements reported here were carried out in the laboratory, the *in vivo* assay can easily be used in the field An alternative method which we also investigated,

Fig. 2 Nitrate reductase assayed on three dates (open columns) and final grain yield (hatched) in barley (*Hordeum vulgare*, var. Julia) plants. Enzyme activity was assayed *in vivo* by the method of Stewart *et al.*[8]. Standard errors: enzyme activity, ±0.155 µmol NO_3^- reduced per h per g; yield, ±238 kg ha^{-1}.



measurement of tissue nitrate, is far more complex and less reliable, and although it yielded similar results in our conditions, it is known that NO_3^- accumulation without related nitrate reduction can occur[5,6]. Although the nitrate reductase measurements do not correlate perfectly with final yield they provide a useful test for future yield except at the highest nitrogen levels and there is at present no remotely reliable alternative. Furthermore preliminary results of Hallam and Blackwood (unpublished) suggest that by careful selection of tissue for assay a correlation which is less time dependent can be obtained. The increasing cost and scarcity of natural resources, the important need to conserve our environment and a continuously increasing worldwide requirement for protein may well make such a test less than a luxury in the near future.

Possible origin for insoluble organic (kerogen) debris in sediments from insoluble cell-wall materials of algae and bacteria

KEROGEN is an inert amorphous organic material insoluble in organic solvents, mineral acids, and bases[1]. In spite of its abundance, the precise molecular structure of this insoluble organic material has long remained an enigma. Structural determinations are complicated by the fact that the structure of any kerogen from different samples varies depending on the types of organic material originally responsible for its formation, and variations in the environmental conditions experienced during and after its formation. We have shown that kerogen-like material can be isolated from recently deposited algal mats. On oxidative degradation this material gives rise to products similar in nature to those obtained by degradation of ancient kerogens known to be of algal origin[2,3]. These results imply that kerogen-like precursors or proto-kerogens, are formed very rapidly on a geological time scale and are found in certain types of recent sediments rich in organic matter.

We have now carried out similar degradation studies on some pure cultures of blue-green and green algae and bacteria, to determine whether the types of degradation products produced would be comparable to those previously obtained from the degradation of ancient kerogens known to be of an algal origin. Microscopic examination of ancient shales, such as the Green River oil shale[4] or Tasmanian tasmanite[5], clearly shows that the bulk of the organic material in these shales is derived from blue-green or green algae, bacteria, fungi and other microorganisms. It is the organic material from the residues of these organisms which represents the starting point in the formation of algal kerogens, although major changes can occur in the structure of the residues after deposition in the sediments and the formation of kerogens. A study of the insoluble organic material from contemporary blue-green and green algae, and bacteria, however, should provide valuable comparative information on the origin and possible method of formation of algal kerogens.

The inertness of kerogen is testified to by the fact that it is the residue which remains after acid treatment of a rock or shale sample to remove minerals, such as carbonates and

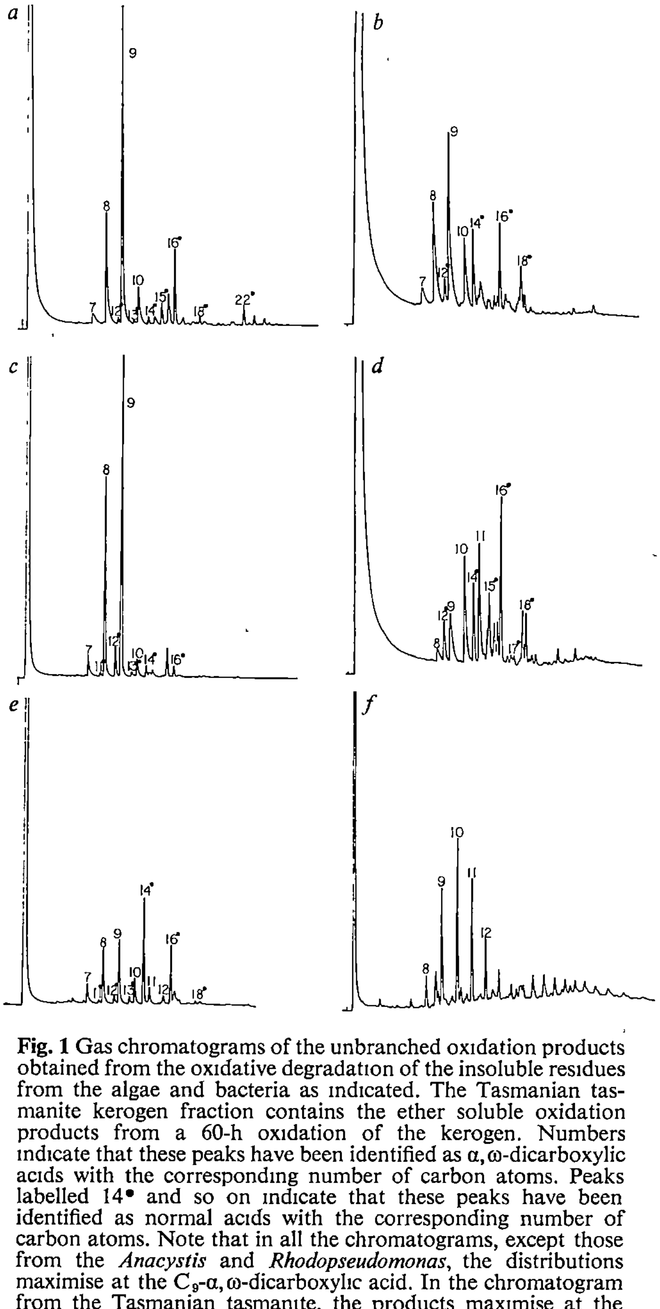

Fig. 1 Gas chromatograms of the unbranched oxidation products obtained from the oxidative degradation of the insoluble residues from the algae and bacteria as indicated. The Tasmanian tasmanite kerogen fraction contains the ether soluble oxidation products from a 60-h oxidation of the kerogen. Numbers indicate that these peaks have been identified as α,ω-dicarboxylic acids with the corresponding number of carbon atoms. Peaks labelled 14• and so on indicate that these peaks have been identified as normal acids with the corresponding number of carbon atoms. Note that in all the chromatograms, except those from the *Anacystis* and *Rhodopseudomonas*, the distributions maximise at the C_9-α,ω-dicarboxylic acid. In the chromatogram from the Tasmanian tasmanite, the products maximise at the C_{10}-α,ω-dicarboxylic acid. Note that the Tasmanian tasmanite chromatogram represents only the ether soluble degradation products; the normal acids, normally extracted with heptane, are not present in this chromatogram. Note, however, that the major degradation products from these organisms are basically the same as those from certain ancient kerogens although there are minor differences in the distributions. These chromatograms were obtained using a Varian 2700 gas chromatogram equipped with a FID detector. A 15-foot × 1/16-inch stainless steel column packed with Dexsil 300 on Gas Chrom Q was used for analysis in the following conditions: oven temperature 100–280 °C, 6° min^{-1}; injector temperature 280 °C; detector temperature 250 °C, and a helium flow rate of 15 ml min^{-1}. Computerised gas chromatography–mass spectroscopy analyses were carried out on a DuPont 491-2 mass spectrometer coupled with a Varian 204 GC Mass spectral data were acquired using a DuPont 21-904 data system. *a*, *Chlorella pyrenoidosa*; *b*, *Chlorobium*; *c*, *Phormidium luridium*; *d*, *Rhodopseudomonas spheroides*; *e*, *Anacystis nidulans*; *f*, Tasmanian tasmanite kerogen.

Table 1 Elemental analyses, yields and ratios of branched–unbranched products obtained from the insoluble organic residues of the organisms indicated

Organisms	Elemental analyses of residues						A*	B†	Ratio of branched–unbranched products
	%C	%H	%N	%O	%S	%Ash			
Algae

*Amount (g) of insoluble residues used in the oxidation reaction.

†Yields (mg) of products obtained on extraction of the oxidation reaction mixture with heptane and ethyl acetate

silicates, and exhaustive extraction of the remaining residue with organic solvents to remove any soluble lipid material[1]. Any humic material can also be removed from this residue by treatment with potassium hydroxide. Kerogen is the most abundant reservoir of organic carbon on the Earth, and as an example of its abundance it has been estimated that there are 3×10^{15} tons of kerogen, compared with 5×10^{12} tons of coal, in the Earth's crust[6].

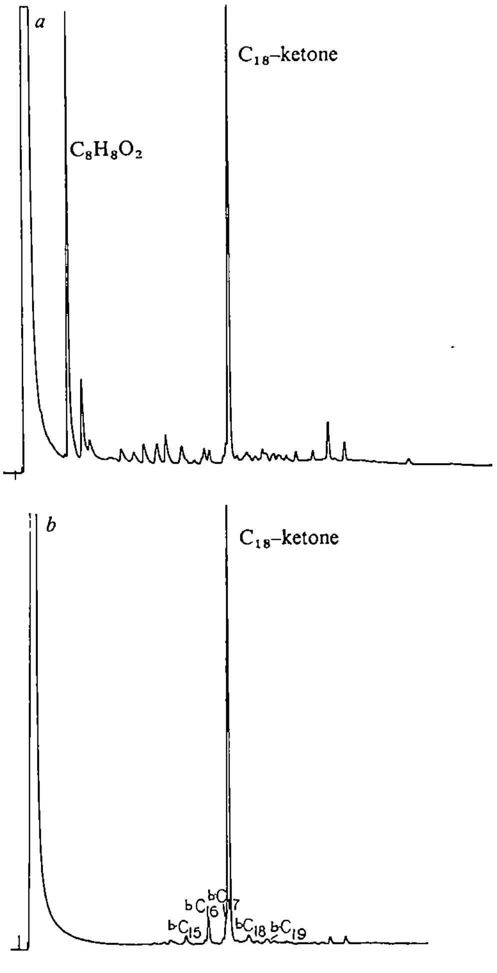
Tissot *et al.* have characterised kerogens as originating either from algal debris, humic or plant debris, or from a mixture of both types of material. Of the two extremes, algal kerogens are generally considered to have an aliphatic-type structure and humic kerogens an aromatic structure[7]. Many chemical and physical degradation studies carried out on kerogens from ancient shales and sediments have yielded valuable, although limited, structural information. The reagents used in chemical degradation studies have included oxidative reagents such as potassium permanganate[8], chromic acid[9], and ozone[10], and reductive reagents such as lithium aluminium hydride[11]. Pyrolysis is another technique which has been used to degrade kerogens[12]. The majority of this work has been carried out on kerogens isolated from such ancient shales as the Green River oil shale[9] (Eocene, 50×10^6 yr) or Tasmanian tasmanite[5] (Permian, $220\text{–}275\times10^6$ yr), (see ref. 8 for additional examples of kerogens examined).

We have carried out degradation studies on the insoluble organic residues obtained from cultures of the algae and bacteria shown in Table 1. The conditions in which these cultures were prepared and the results of the soluble lipid analyses have been described previously[13,14]. Freeze-dried samples of algae and bacteria (Table 1) were treated as for the isolation of kerogen from an oil-shale sample. Each sample was exhaustively extracted with a mixture of toluene–methanol (1:1, using ultrasonication) and after 16 successive extractions the organic extracts were colourless, indicating removal of all readily soluble pigments and lipid material. (It was assumed that ultrasonication was sufficient to rupture the cells; however, the residues were not examined under the microscope either at this stage or after the HCl treatment. The possibility of some intracellular lipids remaining after extraction and hydrolysis cannot be completely excluded.) The residues were subsequently hydrolysed with 6 N HCl and, after centrifugation and removal of the aqueous layer, exhaustively extracted again with organic solvent. In the case of an oil shale, the kerogen is further concentrated by treatment with 48% HF and HNO_3 to remove silicates and pyrites, respectively[1]. This was unnecessary, however, in the case of these pure cultures for obvious reasons.

The resulting residues, after drying, were subjected to alkaline permanganate oxidation described previously[15]. The organic oxidation products were extracted from the reaction mixture with heptane and then ethyl acetate, and these extracts subsequently combined. After methylation of the extracts by BF_3/MeOH, they were fractionated into branched and unbranched fractions by urea adduction. These fractions were subsequently analysed by gas chromatography, and computerised–gas chromatography–mass spectrometry. Components in the various fractions were identified from their relative retention times, coinjection with standards where possible, interpretation of individual mass spectra, and comparison of mass spectra with authentic spectra wherever possible.

Table 1 shows the elemental analyses of the organic residues from the cultures, the yields and relative amounts of un-

Fig. 2 Gas chromatograms obtained of the branched oxidation products from *Phormidium luridium* (*a*) and *Chlorella pyrenoidosa* (*b*). Conditions as in Fig. 1. These two chromatograms illustrate the major features seen in the branched component fractions from all the samples. The C_{18}-ketone was the dominant product in all cases and the second major product was benzoic acid (as the methyl ester derivative used for gas chromatographic analysis). *Chlorella pyrenoidosa* was the exception, in that it was the only sample on degradation to give the isoprenoid acids (the label b-C_{16} indicates the peak corresponding to the C_{16}-isoprenoid acid) shown in this chromatogram.



branched and branched components after oxidation and fractionation. The yields of oxidation products are noticeably low. This is not surprising and was indeed anticipated since it is known that the cell-wall material of blue-green algae consists mainly of protein and polysaccharides[16]. On oxidation this will give rise to water-soluble amino acids and carbohydrates which are removed in the aqueous layer during the extraction of oxidation products. These products were not examined.

Figures 1 and 2 show the chromatograms obtained from the analyses of the oxidation products of the insoluble residues and indicate the components which have been identified. The unbranched fractions were dominated by α,ω-dicarboxylic acids in the range C_6–C_{12} with maximum at C_9 and *n*-acids in the range C_{11}–C_{18} with a maximum at either C_{14}, C_{16} or C_{18} (Fig. 1). These acids were not found in the soluble lipid extracts (except for certain of the *n*-acids[13,14]) of the algae or bacteria and therefore do indeed represent degradation products of this insoluble cell debris. The branched fractions were less complex than the above mentioned fractions and in the majority of cases consisted of benzoic acid, a C_{18}-isoprenoidal ketone (6,10,14-trimethylpentadecan-2-one), and in one example, *Chlorella pyrenoidosa*, of C_{15}, C_{16}, C_{17}, C_{18} and C_{19} isoprenoidal acids in relatively small amounts. These degradation products in turn bear a remarkable resemblance to those obtained from the oxidative degradation of ancient kerogens known to be of algal origin—for example, kerogen from the Green River oil shale[9] or Tasmanian tasmanite[5]. The individual mixtures of products in this study are not anywhere near as complex as those from ancient kerogens. This is not surprising, however, when one realises the differences in age, thermal history, and environmental conditions that have been experienced by the ancient kerogens at the other end of the geological time scale.

There are several possible origins for these degradation products. First, they could be derived from intracellular chlorophyll, which is not removed during the extraction process. This would tend to support the theory of Oehler *et al.*[17] that intracellular chlorophyll becomes grafted on to cellular macromolecules, and with increasing maturation finally gives rise to kerogen. It would also support the theory of Burlingame and Simoneit[18], who proposed that the presence of the C_{18}-isoprenoid ketone in the degradation products of Green River shale kerogen indicated cross linking at the allyl rearrangement centre of phytol (derived from the phytyl side-chain of chlorophyll) during its incorporation into the kerogen moiety.

Second, it is possible that the degradation products are derived from cellular macromolecules which on oxidation give rise to the above mentioned products plus other water-soluble products not examined here. This would support the theory that it is this residual polymeric debris which is the source of the major building blocks of kerogen. With increasing time additional soluble lipid material can become condensed to this basic framework by irreversible chemical reactions, possibly catalysed by clay minerals in the local sedimentary environment. This mechanism plus condensation between the polymeric debris itself would give rise to the kerogen matrix as found in many sedimentary environments.

To extend our theory that the insoluble residues from algae and bacteria are the basic building blocks for kerogen, maturation experiments attempting to incorporate ^{14}C-labelled biolipids into these residues are underway It is anticipated that in simulated geological conditions, the degree of cross linking within the insoluble residues will increase and incorporation of the ^{14}C-biolipids will also occur.

This work was supported by NASA, the A. L. Day Fund, and in part by the US ERDA. We thank Mr S. Brown for assistance; and Dr B. R. Simoneit for a sample of the oxidative products of the Tasmanian tasmanite kerogen.

Prepupal larval mosaics in *Drosophila melanogaster*

THE metamorphosis of insects provides a model system for the study of hormone action. In *Drosophila*, metamorphosis is initiated by the formation of a puparium with a rigid cuticle that becomes tanned early in the prepupal period. Subsequently many larval tissues degenerate and the imaginal tissues develop to produce the adult insect. These processes are initiated in *Drosophila* by the steroid moulting hormone, β-ecdysone[1]. We are interested in the mechanisms by which β-ecdysone elicits adult development. The recovery of mutants which cannot respond to the hormone would facilitate investigation into the nature of the action of β-ecdysone. We have isolated systematically a series of late larval and prepupal X-linked lethals (ref. 2 and unpublished results of I.K. *et al.*), about 15% of which are non-pupariating (*npr*) lethals in which metamorphosis is not initiated. We have investigated whether the *npr* condition is a result of the autonomous inability of the mutant target tissues to respond normally to β-ecdysone or rather is a stage-specific failure in the production of the hormone. Our results indicate that in most *npr* lethals the tissue cannot respond to the hormone. Futhermore, we estimate that there are 100–200 such lethals in the genome of *D. melanogaster*.

One way to investigate whether there is a failure in response to β-ecdysone or a loss of its synthesis for X-linked recessive lethals is to produce gynanders containing patches of male (X/O) tissue in which the recessive lethal is hemizygous (hence potentially expressed) and female (X/X) tissue in which the recessive gene is heterozygous (hence, phenotypically unexpressed). Production of such gynanders in *D melanogaster* is accomplished routinely by crossing ring-X males with females heterozygous for the lethal. In the progeny two types of females are produced; one type carrying the ring X and a lethal-bearing X chromosome, and a second type carrying the ring X and a non-lethal-bearing X (usually a balancer chromosome). During early nuclear divisions in the embryo the ring X chromosome is occasionally lost from some cells with the resultant production of an organism containing both male (X/O) and female (X/X) tissue. For progeny carrying the lethal one would predict that if the *npr* condition were autonomous there

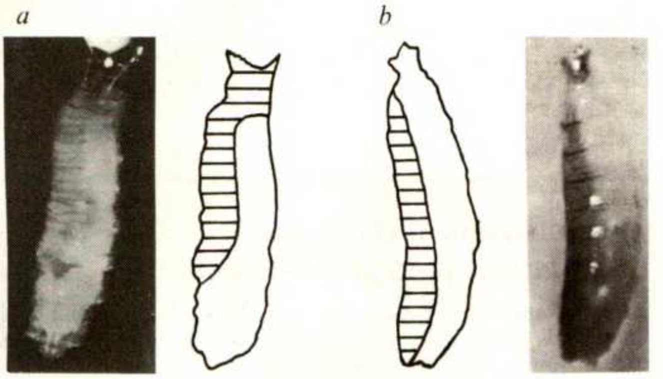

Fig. 1 Photographs and schematic diagrams of larval–prepupal mosaics; *l(1)d. norm.*–1*l*^{a}/*ring* (*l*)*2* (*b*) and *l*(*l*): *d. norm.*–*12*/*ring l*(*2*) (*a*). See ref. 3 and the legend to Fig. 2 for a description of genetic nomenclature and stocks. In the schematic diagrams the cross hatched regions represent tanned puparial tissue.

should be no adult gynanders produced, but instead developmentally arrested mosaics composed of prepupal (X/X) and larval (X/O) tissue. The latter condition would be identifiable readily by the presence of tanned puparial tissue sharply separated by distinct boundaries from white larval tissue.

Such larval-prepupal mosaics were obtained in all of six *npr* mutants investigated. Examples are shown (Fig. 1) involving two independently recovered *npr* lethals. There were sharp boundaries between the larval and the pupariated tissue. For three of the six mutants investigated there was good evidence that some of the mosaics resulted from gyander production. In one case, involving *l(1) d. norm.12*, the maroon-like marker had been added by recombination to the chromosome carrying the lethal. Since *ma-1* lacks aldehyde oxidase activity, male (X/O) tissue will be deficient in the enzyme activity and hemizygous for the lethal, but female (X/X) tissue will have aldehyde oxidase activity and be heterozygous for the lethal. Histochemical identification of the tissue distribution of the enzyme activity using Janning's method[4] revealed perfect correspondence between aldehyde oxidase negative and non-pupariating tissue as expected for male (X/O) tissue in a gynander. (Details of experiments using *ma-1* will be published elsewhere.) In a mosaic involving *l(1) d. norm.-1*^{a}, the anterior of the mosaic was larval, had yellow mouth hooks and thus could be identified as male (X/O) tissue because of the presence of the recessive *yellow* marker on the lethal-bearing X chromosome. The posterior, which had pupariated, contained ovaries, and thus was composed of female (X/X) tissue. In another case, involving *l(1) discless-1*, the larval region of the mosaic contained no imaginal disks while the pupariated region had normal imaginal disks. As a control, females carrying the ring X and a recessive X-linked lethal which causes death after puparium formation, *l(1) d. norm.-6*, failed to produce any larval-prepupal mosaics in contrast to the *npr* lethal *l(1) d. norm.-1*^{a} (Table 1). Adult gyanders of female sibs carrying a non-lethal X chromosome were found easily in both cases. Adult gynanders have not been found for any of the six *npr* mutants investigated. Nevertheless, because of the absence of appropriate markers, we lack evidence that some larval–prepupal mosaics are the result of gynander production for three of the six mutants investigated. Caution in interpretation is necessary because larval–prepupal intermediates can be produced by mistreating larvae (for example, by prolonged immersion in water). The results indicate, however, that 50% or more of X chromosome *npr* mutants involve autonomous defects in the target tissue.

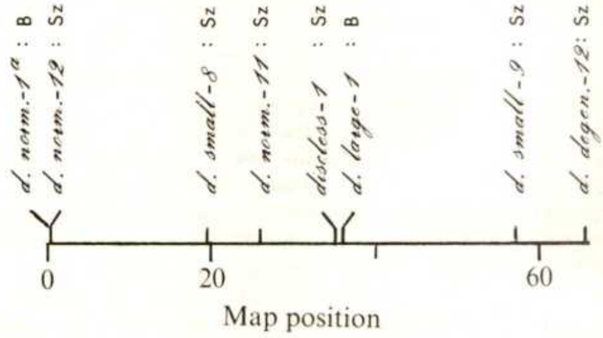

Fig. 2 Map positions of X chromosome *npr* mutants. The methods used for determining map positions are presented elsewhere (ref. 2 and unpublished results of I.K. *et al.*). Mutants isolated in Szeged are indicated by Sz; those isolated in Berkeley by B. The lethals are phenotypically described in terms of the condition of the imaginal disks. Mutant nomenclature: *l(1)*: lethal, first chromosome, has been omitted; *d.*: disk: *norm*: normal; *degen.*: degenerate.

Eight *npr* mutants have been mapped and assigned approximate map positions (Fig. 2). There are at least six (probably seven) loci involved. Based on map position and phenotypic similarity we conclude that two mutants, *l(1) d. norm.-12* and *l(1) d. norm.-1*^{a} are allelic and located slightly to the right of *yellow* (ref. 2 and unpublished results of I.K. *et al.*). Although *l(1) discless-1* and *l(1) d. large-1* map close to each other they are phenotypically very different and probably not allelic. From the above information, assuming that the induction of mutants follows a Poisson distribution, it is possible[5] to estimate the total number of *npr* genes. We calculate that the X chromosome contains about 20 npr genes and the whole genome of *D. melano-*

For a description of genetic nomenclature and stocks see ref. 3 and the legend to Fig. 2. About 10 aged, virgin females were mated in vials with five males. Flies were transferred to fresh vials every 2 d for 2 weeks. Vials were examined twice daily from the emergence of the first offspring until no progeny or live larvae were found over 48 h. Stocks were maintained on standard *Drosophila* medium at 25 °C.

gaster about 100. A similar estimate can be obtained from the percentage of late acting lethals that are *npr* mutants. Of the late acting lethals on the X chromosome 17% (9/53) have the *npr* phenotype (ref. 2 and unpublished results of I.K. *et al.*). Shearn[5] estimates from studies on third chromosome lethals that there are about 900 genes in the *Drosophila* genome which cause late lethality. From this number we estimate that there are about 150 *npr* genes (17% of 900). Kiss and coworkers (unpublished) based on results involving late acting X chromosome lethals, estimate that there are about 750 late acting lethals in the *D. melanogaster* genome, about 125 of which will be *npr* lethals. Although these estimates are approximations, they all suggest that the total number of *npr* genes is small, that is 100–150. Thus, it should be possible to recover mutants of all such X-linked genes and probably of all those on the autosomes as well.

In cases where larval and prepupal mosaicism occurs, the presence of the two types of tissue together in the gynander indicates that the β-ecdysone titre has reached sufficient levels to initiate metamorphosis. Thus, in these cases the mutant tissue cannot respond normally to the hormonal stimulus. We estimate the total number of *npr* genes preventing a specific response of a target tissue to the hormonal stimulus to be 75 or more. But the bases of action of the mutants may be separable into at least three different classes, and all may not be involved in the response to β-ecdysone *per se*. In addition to the category of mutants in which functions necessary to produce a puparium are lost, one can imagine a category of mutants affecting the competence of the epidermal tissue to become programmed to respond to the hormone by puparium formation and a third category in which premature degeneration of the tissue precludes puparium formation. As *in vitro* test systems are available, involving larval target tissues (salivary glands[6], imaginal disks[7] and larval cuticle[8]), it should be possible to investigate the effects of the autonomous *npr* mutants at the cellular and molecular level and distinguish between the above possibilities.

The production of gynanders with both larval and prepupal tissues has implications for studies involving the recovery of adult gynanders. The inability to respond to β-ecdysone implicit in the autonomous *npr* condition is apparently not limited to the larval epidermis, but involves other larval tissues[2]. The maintenance of a substantial fraction of tissue in the juvenile form while another fraction proceeds into and through metamorphosis in all likelihood will result in the failure of eclosion of the adult fly. Thus, even if the effects of the lethal gene are limited to larval tissues, the recovery of adult gynanders might be rendered highly unlikely. Such a case is provided by *l(1) d. norm.-1*^{a} (Table 1) and also by *l(1) d. norm.-12* in which no gynander tissue has been found in carrier adult females (ring/lethal-bearing X) but in which mutant disks develop (albeit poorly) along with the host after transplantation into the haemocoel of a wild type larva[2].

Determination of cell shape by a cell surface protein component

CONSIDERABLE evidence derived from the study of animal cells cultured *in vitro* implicates the cell surface in the regulation of cell division and in the expression of the phenotypic state of the cell. Cell surface is a broad term used to indicate the lipid bilayer of the cytoplasmic membrane containing intrinsic (stably integrated) and peripheral (easily removable) protein constituents plus carbohydrate complexes[1–3]. There are indications that some of the intrinsic constituents are of fundamental importance in certain physiological processes such as ion transport and transport of metabolic precursors[4–8]. On the other hand, it is not known whether components that are more loosely bound to the cell surface play any specific role in cell physiology because no cellular function has so far been examined in relation to such components. We report here that determination of cell shape is affected by a cell surface protein component easily detachable from the cell exterior.

Secondary or tertiary mouse embryo fibroblasts (MEF) derived from the C57BL/6 strain were grown in Eagle's BHK medium supplemented with 5% foetal calf serum. A medium of the same composition and osmolarity as that of the culture medium, but containing no serum (serum-free medium, SFM), was used for washing and incubation during the experiments. Our first aim was to investigate whether any material could be removed from the cell surface without the aid of proteolytic enzymes or chelating agents. Cultures that had been washed

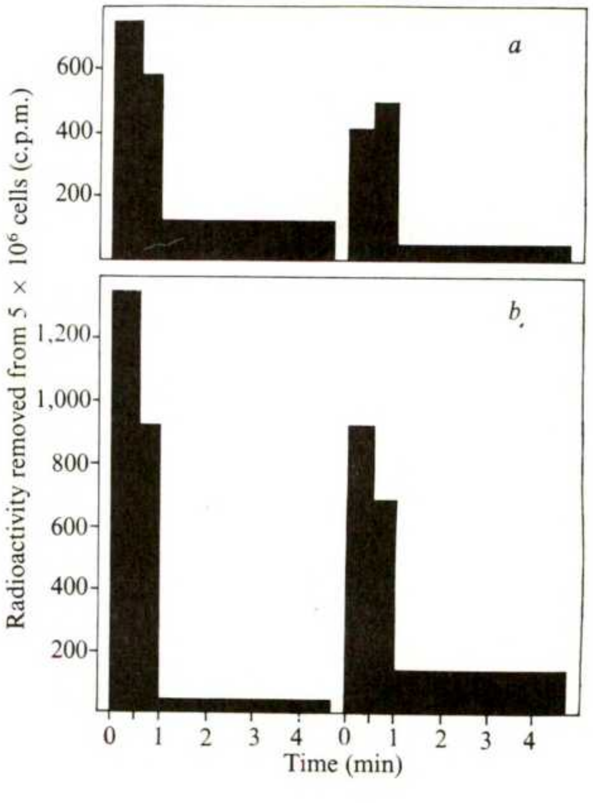

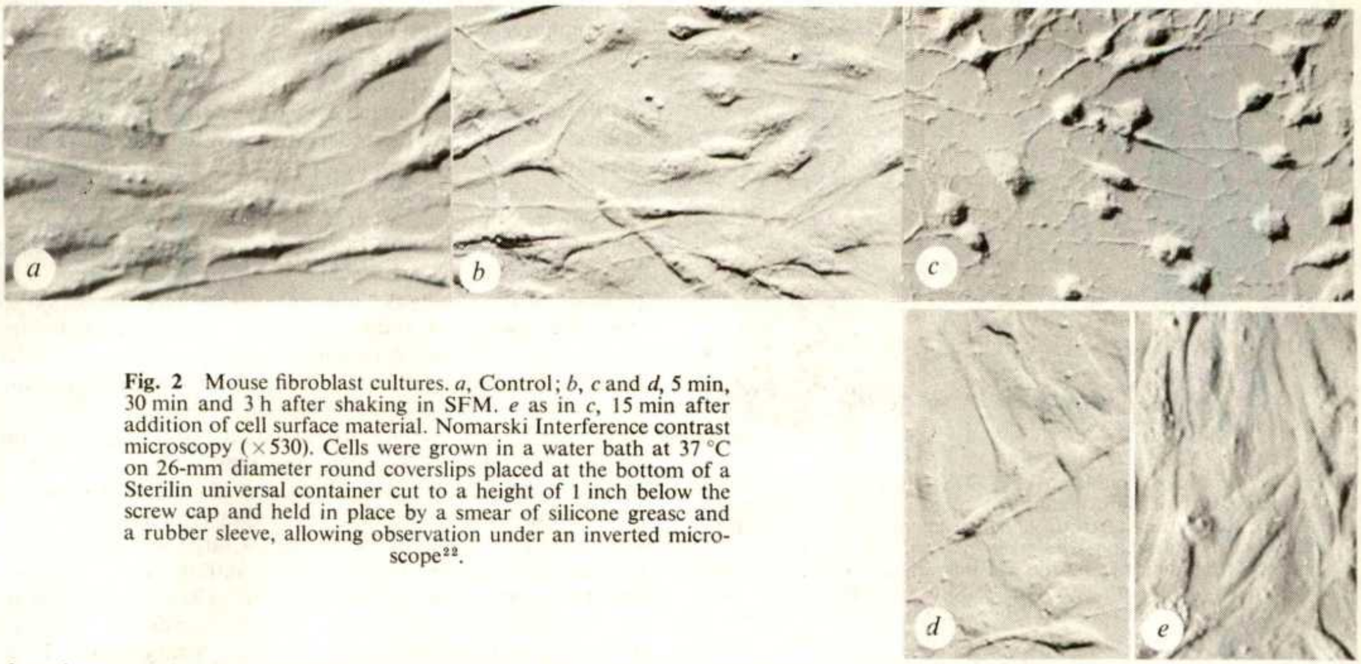

Fig. 2 Mouse fibroblast cultures. *a*, Control; *b*, *c* and *d*, 5 min, 30 min and 3 h after shaking in SFM. *e* as in *c*, 15 min after addition of cell surface material. Nomarski Interference contrast microscopy (×530). Cells were grown in a water bath at 37 °C on 26-mm diameter round coverslips placed at the bottom of a Sterilin universal container cut to a height of 1 inch below the screw cap and held in place by a smear of silicone grease and a rubber sleeve, allowing observation under an inverted microscope[22].

four times were incubated in SFM containing either ^{14}C-protein hydrolysate (50 mCi per matom C, 1 μCi ml^{-1}) or ^{3}H-D-glucosamine-HCl (3 Ci mmol^{-1}, 2.5 μCi ml^{-1}). After about 20 h the radioactive medium was removed, the cells were washed and fresh SFM, a quarter the original volume, was added. The cultures were then placed on a flat surface and submitted to horizontal shaking at 20 °C using a frequency of three excursions per second and an amplitude of 5 inches. The medium from each culture was collected at 30-s intervals, centrifuged at 2,000*g* for 10 min, dialysed in SFM and assessed for radioactivity. Figure 1 shows that both protein and carbohydrate containing macromolecules were freed easily, and that most of the radioactivity was removed with the pattern of a distinct entity within the first minute. A 3-h ^{51}Cr release assay[9] showed no difference between shaken and unshaken cultures, indicating that cell integrity had not been affected by the mechanical perturbation. In fact, the ease with which cellular material could be removed was demonstrated by gentler procedures. Simple SFM washings yielded variable but sizeable amounts of labelled components.

The most obvious and immediate parameter investigated in studies of cell behaviour is form. When returned to an incubator at 37 °C, cells that had been washed or shaken showed a degree of transient rounding. This could be reproduced with uniformity of response and with a consistent kinetic pattern if synchronised tertiary S phase fibroblasts were used and if the shaking procedure described above lasted for a standard period of 1 min. A reduction of the cell projected area and an increase of thickness was noticeable soon after incubation, and was followed by a progressively increasing rounding. At 20 min cells were markedly round with elongated cytoplasmic processes extending in thin ramifications. The rounded state was maintained for a short time, then, gradually, within about 3 h, the cells reverted to their original appearance. Figure 2 *a–d* shows some of the stages in the described sequence of events. Rounding did not occur nor could reflattening take place if the cells were left at or transferred to room temperature.

Among the factors that contribute to determination and maintenance of form are the architectural structures of the cell surface. It seems unlikely, however, when the phenomenon we describe is seen in the light of a cause–effect relationship, that constituents that are stably integrated in the surface membrane could have a primary (first in time) role in the initiation and modulation of the morphological changes as the principle of variation is implicit to the concept of modulation. Thus the induction of rounding that follows shaking in SFM is more likely to be a consequence of the removal of extrinsic factors required for the maintenance of cell shape and reversion to the flattened state to be due to the cell's ability to replace the removed components. To test this possibility we investigated whether the shaken material had any effect on cell morphology. The fraction removed from the cells after 1 min of shaking (Fig. 1) was concentrated by ultrafiltration through Amicon PM-10 membranes (10,000 molecular weight cutoff) to a protein content of 0.5 mg ml^{-1}. Dilutions of this preparation in SFM down to about 50 μg protein per ml prevented the induction of cell rounding when added immediately after shaking and caused rapid reflattening when added to rounded cells (Fig. 2*e*).

We used chromotographic separation to investigate whether this effect was due to the macromolecular complex as a whole or to any components in particular. Concentrated material (2 mg) was loaded on a column of Sephadex G-75 pre-equilibrated and eluted with SFM at 4 °C. Examination of the fractions

showed that only one (no. 13; 20–25,000 expected molecular weight) had the protective activity detectable in the original material. The protein content of this fraction was about 10 μg ml^{-1} but a 1:2 dilution still retained activity. This fraction (no. 13) and the two neighbouring fractions (nos 12 and 14) were concentrated and examined by sodium dodecyl sulphate–polyacrylamide gel electrophoresis[10] in parallel with the original unfractioned material and with a sample of the foetal calf serum used for cultivating the cells. Comparison of the pattern of migration of the banded components after staining of proteins showed that only one band (< 25,000 molecular weight) was unique to those preparations able to maintain or reinduce the flattened state (Fig. 3). The cellular origin of this component was endorsed by the absence of a corresponding band in the serum. Staining of the gels by the periodic acid–Schiff method for carbohydrate[11] did not permit detection of the active component, indicating the possible absence of sugar residues in the protein molecule.

Although the procedure used clearly indicates that several cellular components were loosely attached to the cell exterior and could easily be removed, final identification of the active factor on the cell surface was sought by lactoperoxidase-catalysed iodination (^{125}I) of the intact cells, a technique used to label selectively membrane proteins exposed at the cell surface[12,13]. Parallel ^{125}I labelling of unfractionated material, of Sephadex fractions and of serum proteins was carried out by the chloramine-T method[14]. Lactoperoxidase iodination was done in monolayer cultures that had been washed three times in phosphate-buffered saline (PBS, containing Ca^{2+} and Mg^{2+}) to remove serum. After iodination the cells were washed twice in PBI (sodium iodide instead of chloride as in PBS) containing a protease inhibitor and then collected by scraping. Comparison of the autoradiograms after polyacrylamide slab gel electrophoresis showed a corresponding band in the active Sephadex fraction, the whole cell preparation and the concentrated material removed by shaking in SFM (Fig. 4). No correspondence was found with protein constituents of the iodinated serum. The presence of the common band and its relevance in relation to the effect exerted on morphology was corroborated by the results obtained from densitometric analysis (courtesy of Dr P. Gray, Imperial College, London) of autoradiographs from iodinated active and inactive preparations (Fig. 5).

This report describes an immediate relationship between the physiological state of the cell as expressed by shape and a protein component that originates from the cell surface where sizeable amounts can be removed without the aid of enzymes or chelating agents, as in the case of the large molecular weight surface glycoprotein found in untransformed mouse, hamster and chick cells[13,15–18]. We have evidence that the mechanism by which this component affects cell shape involves a transmembrane effect on the arrangement of the cell's cytokinetic structures, microfilaments in particular. Figure 6 shows that in the flattened state microfilaments close to the surface membrane have an orderly distribution which is modified to condensed patches near the surface when the rounded state is induced. We have found (unpublished work) that the constituent which affects cell shape is spontaneously released in the cell environment and that the extent and rate of this process is greater in quiescent cells. This indicates that the presence of this component within the surface and its con-

centration both at the surface and in the surrounding environment could be an important factor for the determination and modulation of shape during the cell cycle. In a separate report we shall describe its relationship with cytokinetic structures. We have also investigated whether the entire fraction removed by shaking transformed C57BL/6 cell lines[19] in SFM had any effect on the morphology of the normal C57 or 3T3 Swiss fibroblasts, as detectable by prevention or reversion of cell rounding. Table 1 shows that none of these tested materials exerted the marked protective effect shown by the preparation derived from normal fibroblasts. The significance of these results in relation to the presence of a surface factor that affects morphology and its relevance to the phenotypic state and altered growth properties of the cell during transformation will have to be investigated. In view of reports relating cell morphology to concentration of 3′, 5′-cyclic AMP[20,21], endogenous levels of this nucleotide were assessed in the various experimental conditions described above (courtesy of Dr E. Rozengurt, Imperial Cancer Research Fund Laboratories). The results showed that no detectable differences existed and that the changes of shape were not the consequence of variations in the intracellular concentration of cyclic AMP.

We thank the Cancer Research Campaign for support. We also thank Mr J. Crolla for assistance with the interference microscopy, and Dr L. Bannister for electron micrographs.

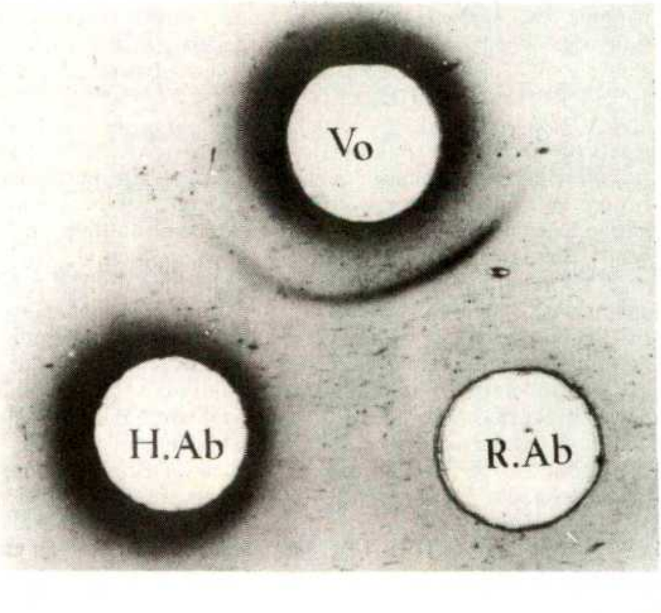
Precipitating antibodies in von Willebrand's disease

WE report the presence of precipitating antibodies in three patients with von Willebrand's disease (VWD), an inherited deficiency of factor VIII (anti-haemophilic factor, AHF). To our knowledge this is the first description of patients with complete biological and immunological deficiency of a plasma-clotting protein responding to replacement therapy by the production of antibodies with properties indistinguishable from those elicited in animals. AHF is a high molecular weight ($> 10^6$) glycoprotein complex[1] associated with two biological activities; one necessary for normal clotting (VIII: C) and the other for normal platelet function (Willebrand factor, VIIIR: WF). Specific antigenic determinants (VIIIR: AG) can be reliably quantified using heterologous antisera[2,3]. Any concept of the structure or the molecular genetics of AHF needs to incorporate the clinical and immunological findings in the two congenital disorders associated with AHF deficiency: haemophilia A and VWD. The former is a sex-linked deficiency of VIII: C alone whereas the latter represents a deficiency of all three parameters of the AHF complex and is inherited as an autosomal trait. Non-precipitating antibodies to AHF, acquired after replacement therapy, are common in haemophilia A (ref. 4) but only one case has been reported in VWD[5,6].

Purified IgG was prepared by precipitation with 40% ammonium sulphate and *n*-octanoic acid[7] from the plasma

Fig. 1 Double diffusion in agarose of purified human AHF complex (Vo) showing a line of identity between homologous antibodies in VWD (H.Ab) and heterologous (rabbit) antibodies (R. Ab).



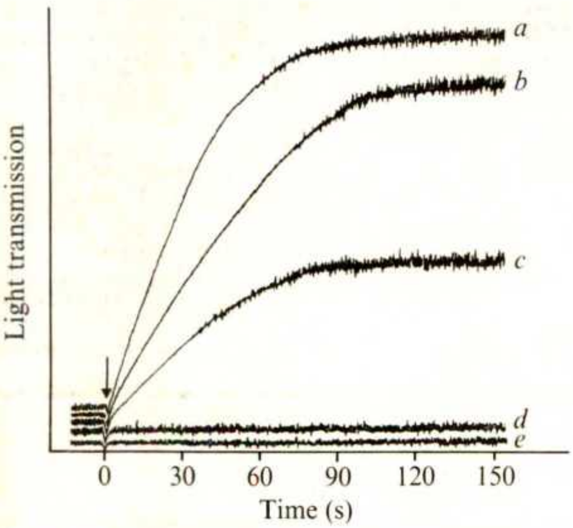


Fig. 2 Inhibition of ristocetin-induced platelet aggregation by plasma from VWD with inhibitor. 50 µl of patient plasma (serially diluted from 1:1 to 1:8) was mixed with 150 µl of normal platelet-rich plasma, followed by the addition of ristocetin (1.5 mg ml^{-1}). The control used was 50 µl of plasma from severe VWD patients with no inhibitor. Similar results were observed with purified IgG from the patients tested using either platelet-rich plasma or normal washed platelets plus normal platelet-poor plasma. *a*, Control; *b*, 1:8; *c*, 1:4; *d*, 1:2; *e*, 1:1.

of three patients with VWD who showed evidence for inhibitor (of 67 tested). The purified IgG in each case gave a line of precipitation with normal and haemophilia A plasma, but not with that of VWD. Precipitation between antibodies and VIIIR : AG from normal plasma was also demonstrated using the Laurell technique[8] and by radioimmunoassay[9]. These homologous antibodies therefore have similar properties to those raised in animals against purified human AHF, which is confirmed by the finding of a line of identity between both types of antibodies (Fig. 1). The purified IgG had a low titre ($<$ U ml^{-1}) of anti-VIII : C, whereas they strongly inhibited VIIIR: WF as measured with ristocetin (Fig. 2). This effect on platelet function was specific for VIIIR: WF, since there was no inhibition of ADP, collagen or adrenalin-induced platelet aggregation. These IgG partially inhibited bovine and porcine AHF-induced platelet aggregation, however, indicating that the effect was not species specific.

Our findings support the contention that VWD is the result of decreased synthesis of normal AHF (ref. 2). Only those rare patients who are completely deficient would have no immunological tolerance to the protein. Our three patients, two of them brothers, had been transfused on multiple occasions because of an unusual severity of the disease. The absence of measurable plasma levels of VIII: C (ref. 10; $<$0.01 U ml^{-1}), VIIIR : AG (ref. 9; $< 2.5\times10^{-4}$ U ml^{-1}) and VIIIR : WF (ref. 11; $<$0.03 U ml^{-1}) and the reduced levels of VIIIR: AG and VIIIR: WF in the parents is consistent with the homozygous state[12,13]. Challenge by transfusion in such patients would be expected to induce an antibody response which, as a result of the multiple antigenic stimulation from a totally foreign protein, could elicit polyvalent antibodies to AHF capable of binding and precipitation. Haemophiliacs seem to synthesise a non-functioning glycoprotein which may have very few antigenic determinants different from normal. Consequently antibodies are more common but precipitation is unlikely to occur because of the paucity of determinants and the difficulty in lattice formation between antigen and antibody.

In conclusion, precipitating antibodies have been found in three polytransfused patients with severe homozygous VWD. Such antibodies seem to be mainly directed towards VIIIR: WF and VIIIR: AG rather than towards VIII: C. Since VIII: C may reside on a separate molecule linked by non-covalent bonds to VIIIR: AG, it remains to be demonstrated whether the partial neutralisation of VIII: C is specific or secondary to steric hindrance.

Control of brain tryptophan concentration in rats on a high fat diet

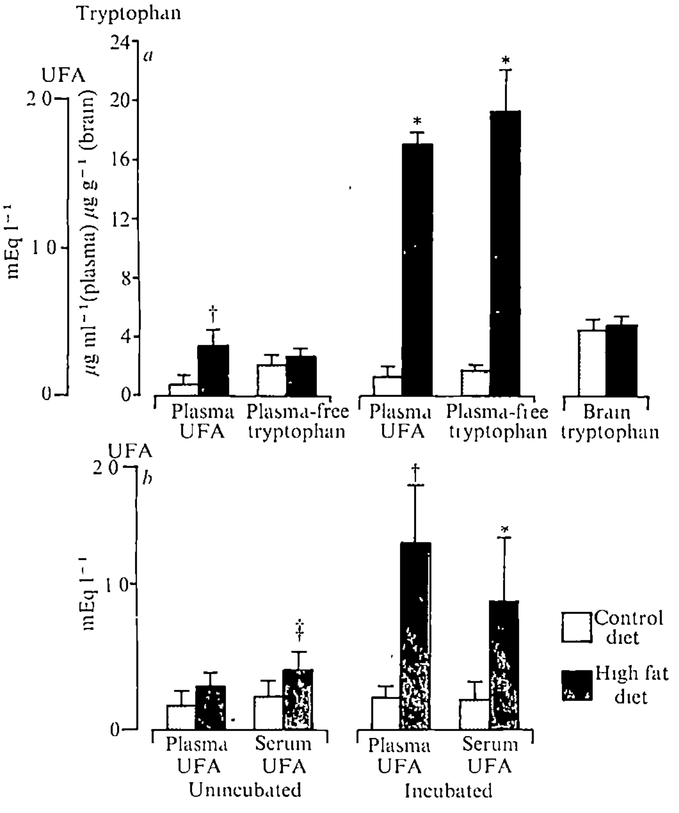
SYNTHESIS in the brain of the neurotransmitter 5-hydroxytryptamine (5-HT) is influenced by the concentration of its precursor tryptophan[1,2]. Much attention has therefore been paid to the determinants of brain tryptophan concentration. Evidence suggests that plasma free tryptophan is an important influence on brain tryptophan[3,4] and that both concentrations increase when plasma unesterified fatty acids (UFA) rise[3,5,6] and release plasma tryptophan from albumin[7,8]. Other results, however, disagree. Thus feeding rats for 2 h with high fat diets apparently led to large increases in serum UFA and free tryptophan but not brain tryptophan[9,10,11]. We now present evidence suggesting that the latter findings may have been due to *in vitro* lipolysis during either the preparation of serum or its dialysis at 37 °C for 3.5 h to separate free tryptophan[9]. Here we describe work in which precautions were taken to avoid *in vitro* changes and which is consistent with a relationship between plasma free tryptophan and brain tryptophan concentrations.

Male Sprague–Dawley rats (200–220 g) (Anglia Laboratory Animals) housed three per cage were maintained on ALGH standard rodent diet (Grain Harvesters) and tap water *ad libitum* and subjected to a 6 h: 18 h light: dark cycle. After a 5-d adaptation period, food but not water was withdrawn at 1600 and on the following day at 0800 the animals were given access to either their normal diet or to a high fat diet (fatty bacon and bread both fried in corn oil). After 2 h they were decapitated and blood was collected into both heparinised and plain tubes cooled in an ice bath, for the preparation of plasma and serum respectively. Total time between blood collection and separation of plasma and serum (by 5 min centrifugation at 2–4 °C) was 10 and 40 min, respectively. Samples of 0.5 ml of plasma were ultrafiltered for free tryptophan determination as before[3], but at 2–4 °C instead of room temperature. Plasma and serum samples (0.1 ml) were also frozen using solid CO_2 immediately after separation for subsequent determination of UFA[12]. Plasma and serum residues were then incubated in a water bath at 37 °C for 4 h, cooled to 2–4 °C and separate plasma samples were ultrafiltered for free tryptophan determination and frozen for determination of UFA as described above. Brains were stored at −20 °C for determination of tryptophan[3].

Plasma or serum samples from rats fed on the high fat diet were all lipaemic while those from control fed rats were all clear. UFA concentrations of unincubated plasmas were significantly greater in the former group and the percentage of free tryptophan increased. But as plasma total tryptophan was proportionately lower in the high fat fed rats (see legend to Fig. 1) free tryptophan concentrations of unincubated plasmas were similar in rats on either diet. As Fig. 1*a* shows, brain tryptophan concentrations were also similar and thus are consistent with the previously found relationship between plasma free tryptophan and brain tryptophan[3–6].

When, however, the plasma of rats given the high fat diet was incubated at 37 °C for 4 h, UFA and free tryptophan concentrations increased five- and sevenfold, respectively. (Plasma UFA had already increased more than fourfold in samples withdrawn after 2 h.) In a separate experiment incubation for 4 h did not alter the *p*H of plasma collected from rats given the high fat diet (before incubation, $p\mathrm{H}=7.75\pm0.05$, $n=3$; after incubation, $p\mathrm{H}=7.78\pm0.06$, $n=3$; values shown ± 1 s.d.). Incubation of plasma from control fed rats led to a relatively small increase in UFA and a negligible change of free tryptophan. The plasma *p*H of a separate group of control fed rats rose significantly ($P<0.001$) during incubation from 7.78 ± 0.03 ($n=3$) to 8.03 ± 0.03 ($n=3$). Comparison with a standard curve obtained by determining free tryptophan in plasma brought to various *p*H values with CO_2 showed that this increase of *p*H would have decreased free tryptophan by about 27%. Even if this is allowed for, it is apparent from Fig. 1 that UFA and free tryptophan both increased massively on incubation of plasmas of fat fed but not control fed animals.

Fig. 1 Plasma and serum UFA, plasma free tryptophan and brain tryptophan in rats fed control and high fat diets. *a*, Relationships between plasma UFA, plasma free tryptophan and brain tryptophan and the effect of incubation *in vitro* on the plasma values. Brain tryptophan of rats killed 2 h after exposure to each diet and plasma UFA and free tryptophan were determined before and after incubation of the same plasma at 37 °C for 4 h (see text for details). Control diet group, $n=6$, high fat group, $n=5$. Differences from values for same but unincubated plasma: $^*P<0.001$. Difference from value for plasma of rats fed control diet: † $P<0.01$. Plasma total tryptophan was 29.15 ± 3.87 μg ml^{-1} and 22.13 ± 3.69 μg ml^{-1} in the control and fat-fed groups (difference: $P<0.01$). *b*, UFA in plasma or serum of rats fed either diet before and after incubation as above (see text for details). $n=10$ per group. Differences from values for same but unincubated plasma or serum: * $P<0.01$; † $P<0.001$ Difference from value for plasma: ‡$P<0.05$



The work of Wurtman's group on free tryptophan and brain tryptophan was carried out not with plasma but with serum[9–11]. Results in Fig. 1*b* show that (in agreement with work on human blood[13]) UFA tended to be higher in serum than in plasma prepared from the same blood specimen. The increase was significant in serum from rats given the high fat diet. UFA (and therefore presumably also free tryptophan) continued to increase when the latter serum was incubated at 37 °C.

These results are consistent with many reports indicating *in vitro* lipolysis in plasma[13–16] especially after intake of fatty food[15], and suggest a reinterpretation of findings previously taken to show lack of effect of large *in vivo* increases of free tryptophan on brain tryptophan in rats fed on fat[9–11]. Considerable *in vitro* increases could have occurred in this work either during the preparation of serum or subsequently (although in one experiment[9] major changes were not found after serum incubation).

Our results therefore strengthen previous evidence that plasma free tryptophan is an important determinant of brain tryptophan concentration[3–6,17]. They do not imply that it is the only physiological influence involved. Insulin secretion, for example, can increase the uptake of tryptophan by the brain, possibly because it decreases plasma concentrations of competing amino acids[9,18,19]. Recent experiments in which plasma and brain tryptophan were determined after giving either insulin or the diabetogenic drug streptozotocin[17] indicate that plasma free tryptophan and insulin changes may influence brain tryptophan concentration concurrently.

We thank the MRC for a programme grant.

Inhibition by albumin of tryptophan uptake by rat brain

CHANGES in the tryptophan content of the brain influence the rate of synthesis of brain 5-hydroxytryptamine (5-HT). Therefore, factors that affect the delivery of tryptophan to the brain may affect its 5-HT content. Tryptophan in plasma can be displaced from its binding site on albumin by non-esterified fatty acids (NEFA)[1] and by certain drugs[2]. Although in some circumstances changes in non-albumin bound (NAB) plasma tryptophan, brought about by drugs and changes in plasma NEFA, parallel those of brain tryptophan[2,3], this relationship does not apply in all conditions. For example, after administration of glucose plasma NEFA decline, as does NAB tryptophan, but the brain tryptophan content increases[4]. Thus, it is uncertain whether binding of tryptophan to albumin is important in controlling brain tryptophan and hence brain 5-HT. To resolve this controversy we looked at the influence of albumin on the uptake of tryptophan by brain *in vivo*. We found that albumin inhibits tryptophan uptake, and that diffusion, a process that will depend only on the NAB plasma tryptophan concentration, has a small but significant role in the uptake of tryptophan by brain.

Tryptophan uptake by the brain was measured by the technique of Oldendorf[5]. Solutions containing ^{14}C-tryptophan and ^3H_2O (as a freely diffusible standard) were injected into the common carotid artery. After 15 s, when excess solution had been washed out of the microcirculation, the rat was decapitated. The $^{14}C{:}^3H$ ratio was determined in the brain and in the injected solution. The ratio for brain, expressed as a percentage of the ratio for the injected solution, is the brain uptake index (BUI).

In agreement with Pardridge and Oldendorf[6] we found that, as the concentration of tryptophan increased, the BUI decreased. BUI is a measure of the uptake of radioactive tryptophan. As the radioactivity in the solution was constant, the product BUI × (tryptophan concentration) is a measure of the total uptake of tryptophan from the injected solution. Figure 1 is a plot of BUI × (tryptophan concentration) against concentration. The uptake was analysed for conformity to one of two models: (1) active transport combined with non-saturable uptake by diffusion, equation (1); and (2) two active uptake systems with differing affinities, equation (2). The method used to discriminate between these models involves initial evaluation of the constants graphically, based on the double reciprocal plot of uptake against tryptophan concentration in the injected solution, followed by an iterative calculation designed to give the best fit of the line to the observed points[7].

$$v = \frac{V_s}{K+S} + K_d S \qquad (1)$$

$$v = \frac{V_1 S}{K_1+S} + \frac{V_2 S}{K_2+S} \qquad (2)$$

The fit to equation (1) was judged the more satisfactory on the basis of the low error mean square (0.0221) as compared with equation (2) (3.83). The fit of equation (1) to the experimental points is shown in line (*a*) of Fig. 1. The values obtained for the constants were $K = 160$ µM, $K_d = 4.51$ and $V = 5{,}920$ µM. By substituting these values in the two parts of equation (1), lines (*b*) and (*c*) were obtained. Note that at 100 µM tryptophan, in the physiological range for that amino acid, diffusion accounts for about 17% of the total uptake. At the concentration of NAB tryptophan found in the normal adult rat—25 µM—the non-saturable mechanism for uptake of the amino acid into the brain accounts for about 12% of the uptake. These data indicate that diffusion of tryptophan across the blood–brain barrier has a small but significant role in regulating the brain tryptophan and, consequently, the content of 5HT in the brain, especially after the administration of a tryptophan load.

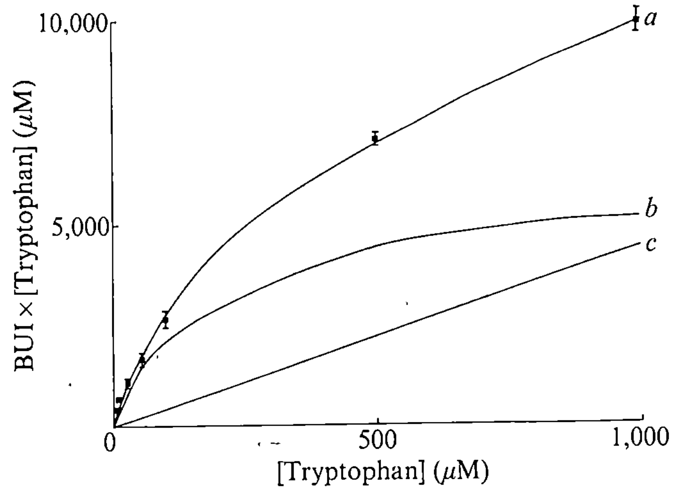

Fig. 1 The variation in tryptophan uptake by brain with various concentrations of tryptophan. A solution containing L-tryptophan, 3 ^{14}C-side chain (40 mCi mmol^{-1}, New England Nuclear) and ^3H_2O (as freely diffusible standard) was injected in the common carotid artery. BUI was measured at the following concentrations of injected tryptophan (TRP) (number of determinations given in parentheses): 6.25 µM (5), 12.5 (13), 25 (20), 50 (13), 100 (13), 500 (3), 1000 (3). The abscissa includes these concentrations The ordinate represents the amount of tryptophan taken up into the brain during the 15-s perfusion (see text). The points represent means ± standard error. Line *a* is drawn as the best fit to the experimental points obtained by methods described in the text. Lines *b* and *c* represent the components of line *a*, corresponding to the saturable and non-saturable processes, respectively.

If the tryptophan is injected in a bolus that contains plasma albumin, the BUI is reduced (Table 1). The addition of albumin to the solution reduced the concentration of tryptophan in free solution from 25 to 6 µM. The BUI for a solution of 6 µM should be, according to the graph in Fig. 1, 70%. But the albumin also reduces the ^{14}C tryptophan in free solution to the same extent, that is to 24% of its original value. Therefore, the BUI that might be expected if the uptake system acts only on tryptophan in free solution is 24% of 70, or 17. This is close, but not identical, to the actual value found, 22 ± 2 (Table 1). Thus, binding of tryptophan to albumin does inhibit its uptake by the brain, and must have some role in regulating the brain tryptophan content.

The uptake of tyrosine, an amino acid that does not bind to albumin, is unaffected by the presence of that protein in the injected solution (Table 1).

Albumin is not the only component of plasma that affects tryptophan uptake. Some amino acids inhibit the process by competing for the same transport system[5]. But this inhibition has been studied so far only with amino acid concentrations beyond the physiological range. Table 2 shows that when the

†For a concentration of 25 μM tryptophan in the injected solution.

concentrations of a group of competing amino acids are raised from the lower to the upper limit of their physiological range there is considerable inhibition of tryptophan uptake. Thus, competition between amino acids for uptake by the brain is a physiological phenomenon, and it is possible that the increased brain tryptophan that is noted after glucose administration[4] occurs because of a decline in the plasma concentration of the competing amino acids. Alternatively, there might be a change in the activity of the actual uptake system. This factor is neglected when measurements are made on plasma and brain tryptophan alone, but it can be studied conveniently by the method of Oldendorf[5]. Studies in which uptake is measured as well as brain and plasma tryptophan content should elucidate fully the influences the components of plasma on brain tryptophan and 5-HT.

Monitoring of transmitter metabolites by voltammetry in cerebrospinal fluid following neural pathway stimulation

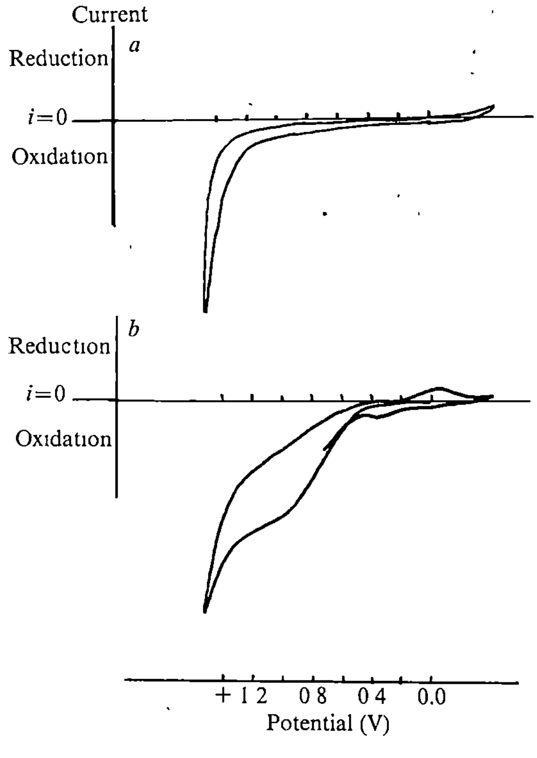
AN *in vivo* voltammetry technique has been developed which enables direct and continuous measurement to be made of the release of neurotransmitter metabolites in cerebrospinal fluid (CSF) after electrical stimulation or pharmacological manipulations of neural pathways. The measurement is very simple in principle. A potential is applied to a micro carbon electrode stereotaxically placed in a lateral ventricle. One then measures the minute current which results from the oxidation or reduction of small molecular weight constituents near the sensor electrode. The potential at which the electrolysis occurs serves as a qualitative indication of the constituent being monitored and the current itself is directly proportional to the concentration of this component in CSF.

The catecholamines and all their metabolites, as well as 5-hydroxytryptamine and its metabolites, are readily oxidised. Thus, the technique is applicable to catecholaminergic and serotoninergic neurotransmitter systems. Acetylcholine, GABA and various other aliphatic amines and acids which have suspected neurotransmitter roles are not electroactive and are not sensed by the electrode in the conditions used. We have previously described the *in vivo* voltammetry method especially for examining drugs injected directly into brain tissue[1,2]. We believe the present application is particularly significant because it provides continuous readout of CSF metabolites following stimulation of neural pathways without the necessity for perfusion or radioactive labelling.

In one test of the technique, we examined the metabolites transferred to the CSF following electrical stimulation of a well-established neural substrate, the dopaminergic nigrostriatal pathway. Rats were implanted with conventional bipolar stimulating electrodes in the pars compacta of the substantia nigra. At the same time, one or both lateral ventricles were implanted with a small guide cannula. Following several days of surgical recovery, the rat was anaesthetised and placed in the head holder of a stereotaxic apparatus. A micro carbon electrode was inserted in the cannula to a depth which ensured contact with the CSF of the lateral ventricle. It is well known that electrical stimulation of the substantia nigra causes a release into the CSF of the dopamine metabolite homovanillic acid (HVA)[3,4]. The latter was the sought-after electroactive component in these experiments.

Figure 1 illustrates the qualitative aspects of the electrochemical experiment. The cyclic current–voltage curves (voltammograms) of Figs 1*a* and *b* were initiated by a triangular wave potential sweep from 0.0 to 1.4 V and then returned to −0.2 V. (All potentials are measured against a micro saturated calomel electrode (SCE) normally placed in contact with brain tissue over the frontal sinus area.) Figure 1*a* shows the baseline level of com-

Fig. 1 Electrochemical signals in CSF at micro carbon electrode. *a*, Before stimulation; *b*, after stimulation.



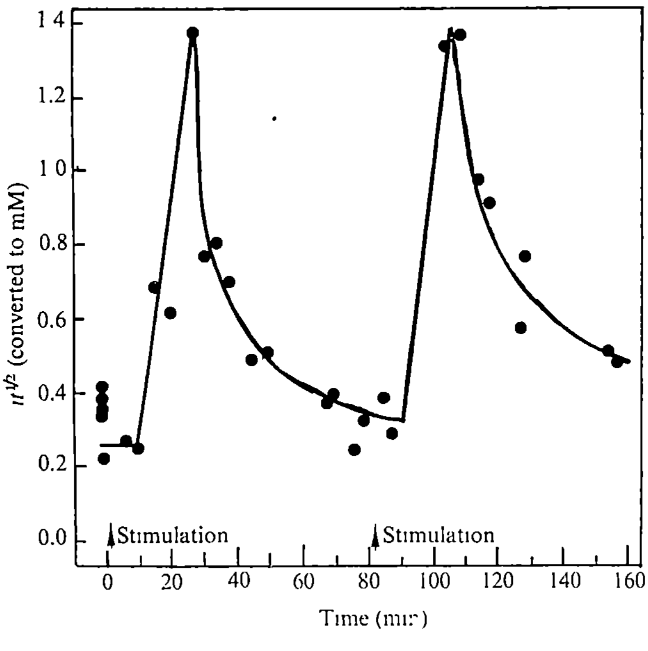
ponents in the CSF which can be oxidised within this potential range (primarily ascorbate and micromolar levels of HVA). At the current sensitivity used, very little oxidation current is seen in Fig. 1*a* in these "resting" conditions. Following stimulation of the substantia nigra, Fig. 1*b* shows a large current with a plateau at around +0.8 V which is a result of HVA oxidation. (Although this is a large increase, all electrochemical currents referred to herein are at most several hundred nA.) The small peaks around +0.1 V in Fig. 1*b* come from oxidation and reduction of dihydroxyphenylacetic acid (DOPAC) and its *o*-quinone. It is well established that DOPAC is formed during the electrolysis of HVA[5,6], and the small peaks serve as an additional electrochemical "marker" for the presence of HVA.

The quantitative measurements are carried out by fixing the potential at +0.8 V and monitoring the current due to HVA oxidation as a function of time. Before stimulation only the low baseline signal illustrated in Fig. 1*a* is monitored at +0.8 V. The substantia nigra was then stimulated for 20 0.5-s intervals using simple 60-Hz sine waves. In typical experiments, the baseline remained relatively constant for some 15–20 min after stimulation. There then was a sharp rise in HVA signal, followed by a more gradual disappearance. Often such stimulations could be repeated several times and Fig. 2 shows a typical result of two successive stimulations. Successful experiments were carried out with 12 of 22 rats stimulated. Because of difficulties with cannula placement in rat ventricles (our electrodes at present require cannulae of around 1 mm external diameter), we have recently repeated this type of experiment in rabbits. To date, four successful substantia nigra stimulations have been carried out with rabbits. It should be emphasised that no optimisation of stimulation parameters, anaesthetics, electrode size and so on has yet been investigated. A full report of the experimental details is in preparation.

Similar electrical stimulation was carried out in the region of the midline raphe nuclei with rabbits. As expected, an efflux of 5-hydroxyindole acetic acid (5-HIAA) into the CSF was observed by the voltammetric monitoring, but little or no change in HVA.

Pharmacological manipulations of neural substrates can also be monitored by this technique. For example, a large increase in HVA signal in ventricular CSF was observed some 30 min after an intraperitoneal injection of L-dopa in the rabbit.

Fig. 2 HVA current response in CSF following substantia nigra stimulation. Current-time product for 200-ms electrolysis was converted to mM concentrations of HVA by external calibrations.



Since this type of electrochemical measurement is unfamiliar in electrophysiological studies, we expected its authenticity to be quite properly open to question. Thus, electrochemical measurements were routinely backed up by independent and unequivocal chemical identification of HVA, DOPAC or 5-HIAA by high performance liquid chromatography. When a successful stimulation or drug manipulation was obtained—as evidenced by a current rise at the sensing electrode—we lifted out the electrode and removed 2–5 ml of CSF with a Hamilton syringe. The CSF sample was injected directly into the injection port of a liquid chromatograph. The metabolites were directly analysed by high performance liquid chromatography on a DuPont SAX anion exchange column with a sensitive electrochemical detection system[7]. The CSF metabolites were identical with authentic samples injected into the column and quantitative correlations were possible.

We believe that the present technique will offer distinct advantages over existing methods for examining metabolite changes in CSF following neural pathway manipulation. It is the only technique we know making use of an on-line sensor that provides instantaneous and continuous monitoring of CSF metabolite levels (electrochemical response times are variable, but routinely are 10–20 ms). It involves minimal disturbance of the physiological milieu; electrical currents are always in the nA range and natural CSF and its flow patterns are used rather than perfusion. It is, of course, limited in its scope to the oxidisable neurotransmitter systems and their metabolites, as mentioned earlier. Although the present results are very promising, improvements in electrode miniaturisation, sensitivity and selectivity are desirable. We are now examining modifications to extend the technique to direct tissue measurements with neuronal pathway manipulation.

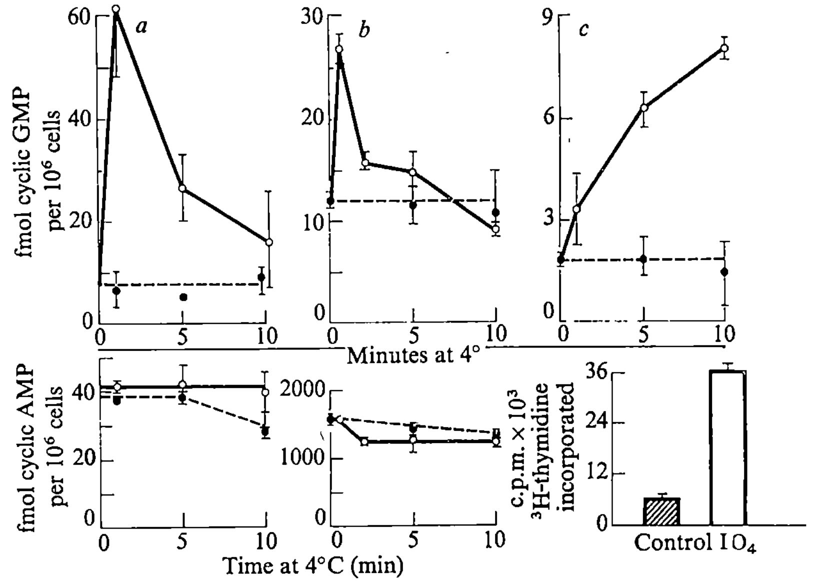
Periodate-induced increase in cyclic GMP in mouse and guinea pig splenic cells in association with mitogenesis

INTERACTION of the lectins phytohaemagglutinin (PHA) and concanavalin A (con A) with the lymphocyte plasma membrane initiates a sequence of metabolic events leading to cell proliferation. The numerous alterations in cellular components and processes that occur early after mitogenic stimulation include enhanced uptake of nucleotides[2], amino acids[3,4], sugars[5], Ca^{2+} (ref. 6), and K^{+} (ref. 7), enhanced activity of several membrane enzymes[8,9], accelerated turnover of phospholipids[10,11], increased membrane fluidity[12] and an increased accumulation of cellular cyclic 3′,5′-guanosine monophosphate (cyclic GMP)[13–15]. Demonstrations that exogenous cyclic GMP can stimulate definable functions in lymphocytes[16,17], including proliferation[18], and

Fig. 1 Cyclic GMP and cyclic AMP levels and ^{3}H-thymidine incorporation after exposure of mouse splenic cells to IO_4. Spleens, removed from cervically dislocated 6–8-week-old BALB/c mice, were homogenised gently in PBS After sedimentation of connective tissue the suspended cells were removed, washed with PBS, and suspended at 20 × 10^6 cells per ml PBS. The IO_4, freshly dissolved in PBS, was introduced to achieve a final concentration of 5 mM while the cell suspension was maintained at 4 °C. Samples were collected for determination of cyclic nucleotides by adding perchloric acid to a final concentration of 1N. Acid extracts were purified by alumina and AG1X8 column chromatography, and assayed by radioimmuoassay[28] after conversion to the 2′-*O*-acetyl derivative[29] Cells in which the proliferative response was monitored were exposed to the IO_4 for 30 min, washed twice with PBS, and suspended at 2 × 10^6 cell per ml in RPMI 1640 containing foetal calf serum (5%), penicillin (110 μg ml^{-1}) and streptomycin (100 μg ml^{-1}). The cells were incubated in 5% CO_2 at 37 °C for 48 h before a terminal pulse with 1 μCi ^{3}H thymidine for 3 h Cultures were collected by a multiple automatic sample harvester and thymidine incorporation was determined by liquid scintillation spectrometry. The broken lines represent controls.



that there is an association between phytomitogen action and cyclic GMP accumulation suggest that this nucleotide is a positive effector of proliferation. To investigate further how cyclic GMP may be involved in this sequence of events, we have studied the effects that the oxidant periodate (IO_4) and the reducing agent cysteine have on the cyclic nucleotide levels of rodent splenic cells[1]. IO_4 stimulates lymphocyte proliferation[19] and because the oxidant produces definable chemical alterations in membrane components, which can be prevented by reducing agents[20], studies with these agents may provide insights into the regulation of cyclic GMP metabolism in relation to mitogenic stimulation.

Figure 1 shows the effect of IO_4 on the concentrations of the cyclic nucleotide in suspensions of mouse splenic cells, maintained at 4 °C, in three experiments The concentrations of cyclic GMP in the cells not exposed to the mitogen varied from animal to animal, ranging from 2.5 to 12.5 fmol per 10^6 cells. In spite of the variation, treatment with IO_4 consistently caused an enhanced accumulation of cyclic GMP but did not alter the concentration of cyclic 3′,5′-adenosine monophosphate (cyclic AMP). The increase in cyclic GMP concentration ranged from two- to tenfold and the temporal characteristics of the enhanced accumulation differed in each experiment shown. The IO_4-induced increases in cyclic GMP were accompanied by a stimulation of lymphocyte proliferation as illustrated by the increased amount of ^{3}H-thymidine incorporated into cells cultured after exposure to IO_4 (Fig. 1*c*).

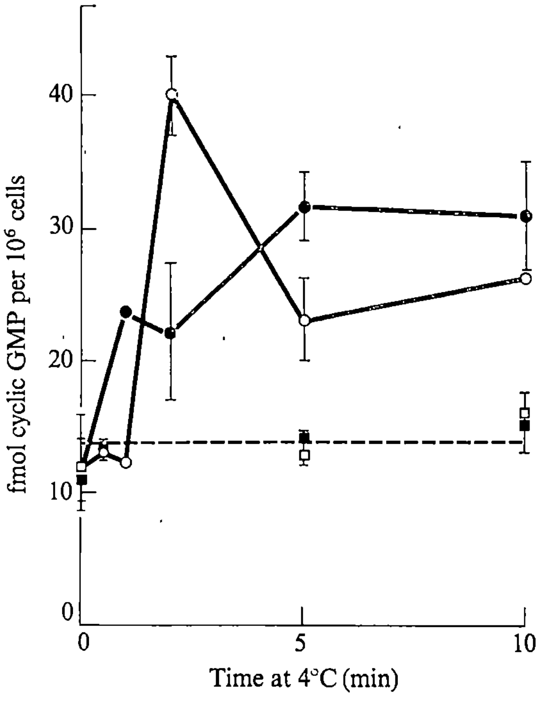
The cyclic nucleotides in guinea pig splenic cells responded similarly when exposed to IO_4; cellular levels of cyclic GMP increased but cyclic AMP was unaffected (Fig. 2). The addition of $CaCl_2$ (0.2 mM) to the cation-free phosphate-buffered saline media (PBS) did not enhance the ability of IO_4 to promote accumulation of cyclic GMP.

The reducing agent cysteine prevented the IO_4-promoted increase in cyclic GMP. Cysteine alone or together with IO_4 significantly lowered (50%) the concentration of the cyclic nucleotide (Fig. 3). The increase in ^{3}H-thymidine incorporation seen after exposure to IO_4 alone was prevented in the cells exposed to IO_4 in combination with cysteine. There was no change in the cyclic AMP content after the addition of either the oxidising or the reducing agent.

Thirteen experiments were conducted to examine the effects of IO_4 on cyclic GMP levels. In the nine experiments in which an increase in cyclic GMP was detectable (70–1,000%) there was a concomitant increase in the rate of ^{3}H-thymidine incorporation. But in the other four experiments there was no measurable increase in either cyclic GMP or in ^{3}H-thymidine incorporation, indicating that IO_4 had no oxidative influence in these experiments.

The increases in cyclic GMP detectable after exposure to IO_4 were smaller than those reported after stimulation of human or rodent peripheral blood lymphocytes with PHA or con A[13,14]. This may reflect the difference between the cell populations studied or a difference in the nature of the mitogenic stimulus. In the conditions of mitogenic stimulation in our experiments, however, the changes occurred at 4 °C, which may have minimised the increases. Furthermore, splenic cell suspensions, although consisting primarily of lymphocytes, contain other cells such as polymorphonuclear leukocytes and macrophages. It is not possible to determine from the experiments reported here

Fig. 2 Effect of IO_4 on cyclic GMP of guinea pig splenic cells in the presence and absence of Ca^{2+}. Cell suspensions were prepared from guinea pigs (250–350 g) as described for Fig. 1. $CaCl_2$ (0.2 mM) was added to the cells suspended in PBS at 4 °C 10 min before addition of IO_4 (5 mM). ●, Plus Ca^{2+}; ○, without Ca^{2+}; ■, control plus Ca^{2+}; □, control without Ca^{2+}.



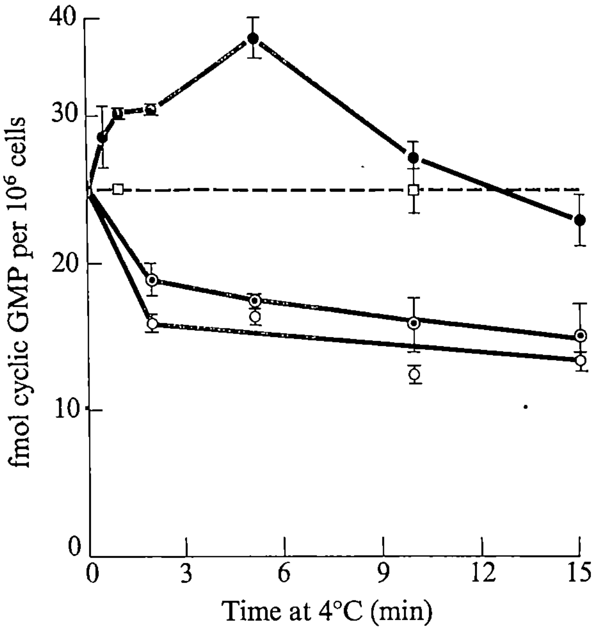


Fig. 3 Effect of cysteine on basal (○) and IO_4-stimulated (⊙) cyclic GMP of mouse splenic cells. All methods were as described in Fig. 1. Cysteine (1 mM) was added to the cells just before addition of the IO_4 (1 mM). ●, Plus IO_4 alone; □, control.

whether the increases in cyclic GMP derived from an alteration induced in lymphocytes directly or secondarily, or whether they reflect an influence on another cell type. The importance of this question increases in the light of demonstrations of a requirement for macrophages for IO_4 stimulation of lymphocytes[21] and of an involvement of cyclic GMP in the release of lymphocyte-stimulating factors by macrophages[22].

The ability of IO_4 to stimulate an increase in cyclic GMP suggests that an alteration of the cell membrane involving oxidation of a specific constituent, such as the sialic acid moiety indicated by the work of Novogrodsky[20], is coupled to a system involved in regulating guanylate cyclase. The reciprocal effects of IO_4 and cysteine on cyclic GMP suggest a mechanism for regulating guanylate cyclase activity through cellular events involving oxidation and reduction. This concept is supported by observations that soluble fractions of guanylate cyclase from platelets[23], and lung[24], as well as from lymphocytes (M. K. H., J. H. S. and N. D. G., unpublished observation), undergo a time dependent, O_2-requiring "autoactivation" which is inhibitable by the reducing agent dithiothreitol. Such a mechanism may be allied to that by which oxidation and reduction have been suggested to underlie the modulation of cell proliferation[27].

It is not known whether all the metabolic changes occurring early after mitogenic stimulation of lymphocytes are necessary for DNA synthesis; whether some, although not absolutely required, serve to modulate the rate of proliferation, or whether some are merely related to the generalised changes in the membrane. The number and variety of early events suggest that no single event signals commitment to proliferation.

Agents such as acetylcholine and imidazole can increase cyclic GMP in lymphocytes without promoting proliferation although they potentiate the action of phytomitogens[25,26]. Therefore, the increased cellular accumulation of this cyclic nucleotide is probably not the sole initiator of proliferation, but rather, acts in parallel or in sequence with the other metabolic changes resulting from mitogenic action.

Evidence for non-deoxynucleotide linkers in Ehrlich ascites tumour cell DNA

ALTHOUGH many authors have used lysis of eukaryotic cells on alkaline sucrose gradients to measure the size of single-stranded DNA subunits, these studies cannot distinguish a true DNA subunit from a subunit containing non-DNA, alkali-stable linkers. We report here that when Ehrlich ascites tumour (EAT) cell DNA is treated with Pronase before alkali denaturation the size of the released subunit changes from $>$70S to 26S. T7 DNA present throughout remains unchanged in size, indicating that the change is not due to a soluble nonspecific nuclease.

Kavenoff and Zimm[1] have shown that the double-stranded DNA from *Drosophila* cells seems to be continuous throughout the length of the chromosome. These results do not, however, rule out the possibility of single-stranded nicks or non-deoxynucleotide linkers[2]. When eukaryotic DNA is lysed in alkali and measured either in alkaline sucrose gradients[3–6] or by viscoelastic techniques[7–8], it seems to have a molecular weight of 1×10^8–2×10^8 or larger. Although there is some disagreement, most authors consider this material to represent single-stranded DNA, particularly if the DNA is allowed to stand in alkaline detergent solutions for 3–6 h[4,5,7].

We also observe that nearly all the DNA of EAT cells (Gφ strain)[9] sediments faster than T4 (not shown) or T7 marker DNAs in alkaline sucrose gradients (Fig. 1*a*). This DNA has a molecular weight of 0.9×10^8–1.2×10^8 (not

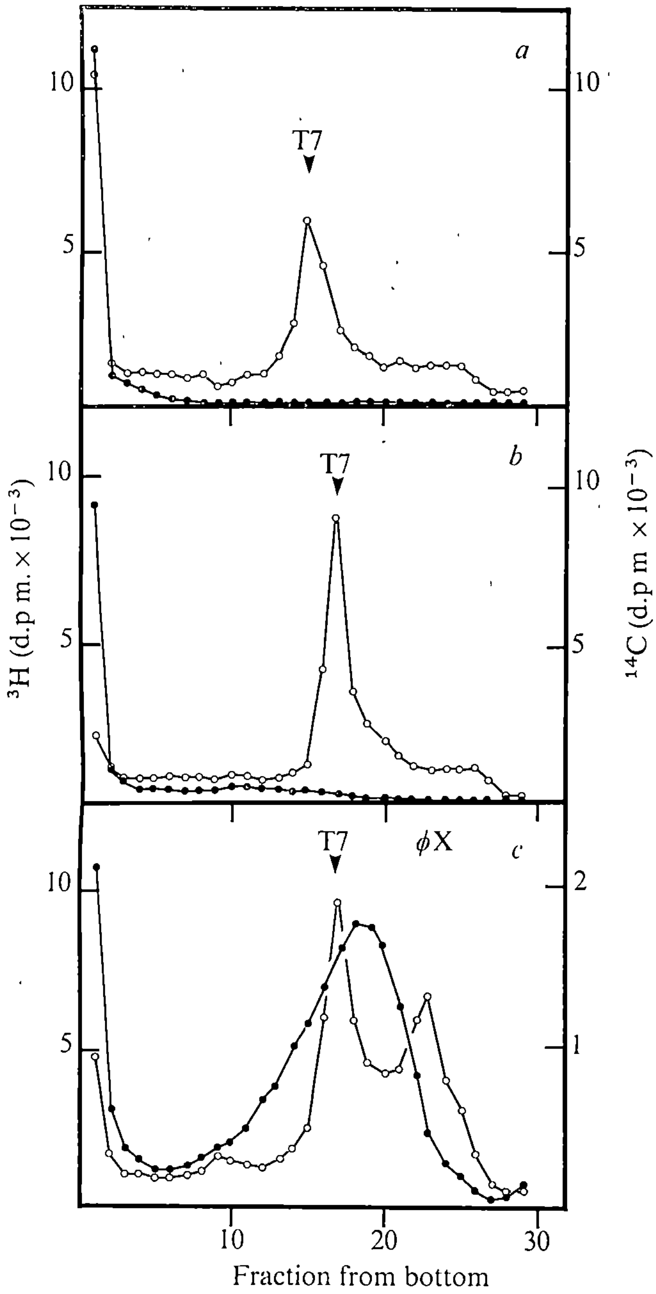

Fig. 1 Ehrlich ascites tumour cells were labelled by intraperitoneal injection of 5 μCi ^{14}C-thymidine (Amersham-Searle). The next day the cells were collected, washed twice by centrifugation in Hanks balanced salt solution, and suspended in 0.01 M EDTA, *p*H 7.5, at 10^{7} cells per ml. A cell suspension (0.5 ml) was added to 0.5 ml of lysis buffer at 50 °C in polyallomer SW 27 centrifuge tubes. The final concentrations in the lysate were 0.5 M NaCl, 0.05 M EDTA, *p*H 7.5, 0 3% sarkosyl detergent. ^{3}H-labelled T7 and ΦX phage markers and pretreated (10 min at 80 °C, 1 h autodigestion at 37 °C) Pronase P (3 mg ml^{-1}, Serva), when included, were present before addition of the cell suspension. Lysis was instantaneous. *a*, NaOH (0.1 ml of 1N) was added before cell lysis. After this alkaline lysis (*p*H 12), the lysate was at 20 °C for 9 h before gradient formation. ^{3}H-T7 was present throughout. *b*, Cells lysed at 50 °C in buffer without Pronase and incubated at 50 °C for 5 h, followed by addition of 0.1 ml 1 N NaOH for 4 h. ^{3}H-T7 was present throughout. *c*, Cells lysed at 50 °C in buffer with Pronase and incubated at 50 °C for 5 h, followed by addition of 0.1 ml 1N NaOH. ^{3}H-T7 and φX were present throughout 5–20% alkaline sucrose gradients containing 0 2 M NaCl, 0.3 N NaOH, 0.05 M EDTA, and 0 3% sarkosyl were formed beneath the lysate. Centrifugation was at 25,000 r.p m., 4 °C, for 12 h. Gradients were pumped from the bottom, fractions precipitated on Millipore filters with 10% trichloroacetic acid, washed with TCA and ethanol, and counted. ●, ^{14}C-labelled cell DNA; ○, ^{3}H-labelled phage DNA.

shown) after alkaline lysis for 3–6 h at a *p*H which is sufficient to denature DNA completely[4,7] and to dissociate all but the most tightly bound material. In agreement with previous research[8], very little cell protein cosediments with the rapidly sedimenting material. Indeed, only three protein bands are observed electrophoretically after protein specific iodination of this material (U. Plagens and D. Werner, unpublished). Shear was minimised by lysis of the cells and markers in polyallomer centrifuge tubes with subsequent formation of the sucrose gradient beneath the sample. If the cells were lysed initially in a neutral lysing solution and only made alkaline after 3–6 h at 50 °C, the DNA still sediments faster than 70S (Fig. 1*b*). Similar results are obtained at lower temperature, lower salt, less EDTA and sodium dodecyl sulphate (SDS) instead of sarkosyl. But if Pronase (3 mg ml^{-1}, heated to 80 °C for 10 min, autodigested at 37 °C for 60 min and exhibiting no nuclease activity on phage DNA) is present in the neutral lysing conditions, more than 80% of the single-stranded DNA released by alkali now sediments at 26–35S (6×10^{6}–12×10^{6} daltons) (Fig. 1*c*). This is more than an order of magnitude smaller than the smallest subunits observed after lysis of cells directly on alkaline sucrose gradients[3–6]. After exhaustive digestion with Pronase, the peak reaches a limit at 26S. With less extensive digestion, the peak is broader and closer to 35S. In each case, T7 marker DNA was present throughout the lysis and incubation of the cells. The marker remained apparently unchanged, giving an initial indication of the absence of substantial soluble DNase activity, either in the presence or absence of Pronase. Moreover, only in the case of immediate lysis in alkali is there any evidence of substantial entrapment of T7-sized DNA with the cellular DNA sedimenting to the bottom. Thus, there is no evidence that the rapidly sedimenting DNA observed in the absence of Pronase is a nonspecific aggregate of 26S subunits.

To more explicitly detect any DNase activity in, or activated by, the addition of Pronase, the experiment described in Fig. 2 was performed. ^{3}H-T7 was present during the neutral lysis of cells in the presence of Pronase and subsequent alkaline denaturation and ^{32}P-T7 was then added to the alkaline lysate (Fig. 2*a*). The label present throughout lysis and the label added only after alkaline denaturation cosediment. Alkaline lysis of the phage in the absence of cells and Pronase gives similar patterns (Fig. 2*b*) as does digestion of phage DNA with Pronase in the absence of cell DNA. The small excess of more slowly sedimenting material in the ^{3}H-labelled phage is also observed if the order of addition of phage is reversed. Similar lack of nuclease activity is observed for φX and λ DNA markers. It is thus unlikely that the change observed in the size of alkaline denatured EAT DNA after digestion with Pronase is due to a soluble DNase, since such a DNase activity must be able efficiently to recognise a site present in EAT DNA but not in any of the phage DNAs tested and to show this specificity in high salt, the absence of divalent ions, and detergent at 50 °C.

There are two general explanations for these results. EAT chromatin may contain a tightly-bound nuclease which is activated by the Pronase treatment. Such a tightly-bound nuclease activated by Pronase, SDS or heat has been described associated with colE1 plasmid DNA[10]. Alternatively, EAT DNA may contain a non-deoxynucleotide linker which is cleaved (or made alkali labile) by the Pronase treatment. Possible candidates for such a linker might include: (1) a modified, alkali-resistant ribonucleotide, such as a 2′-*O*-Me ribonucleotide, which is susceptible to an RNase activity present in, or activated by, the Pronase; (2) an RNA linker protected from alkaline degradation by a protein, either covalently linked or tightly-bound, and thus made susceptible to alkaline lysis after Pronase digestion, and (3) a protein or peptide linker in the DNA.

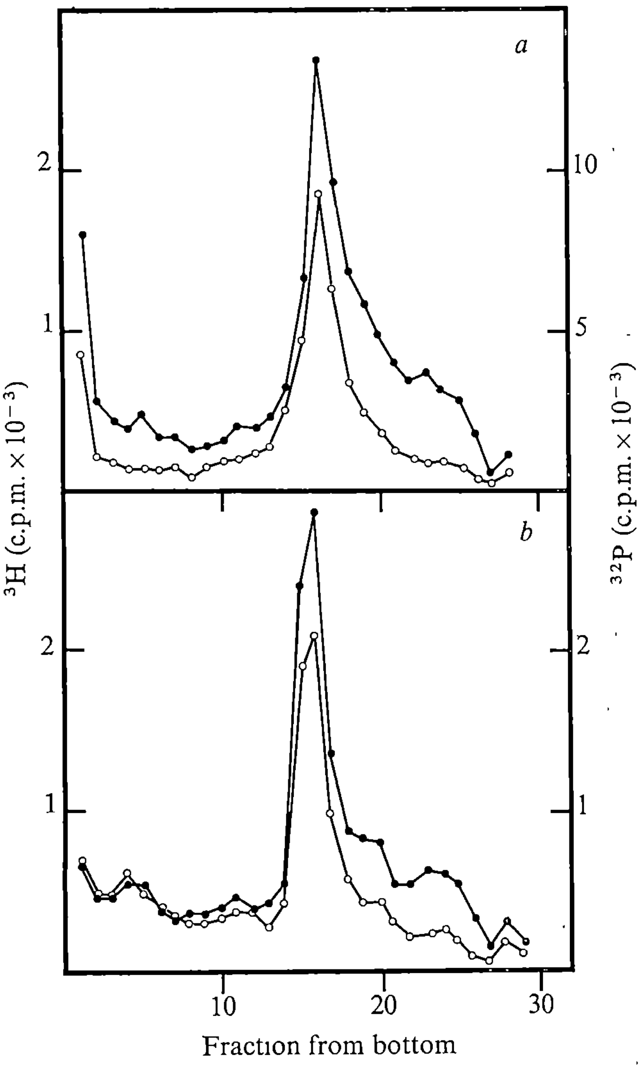

Fig. 2 *a*, 5 × 10^6 unlabelled Ehrlich ascites tumour cells were lysed in 1 ml of lysis buffer containing Pronase (3 mg ml^{-1}) and ^{3}H-T7 phage marker The lysate was incubated for 5 h at 50 °C, followed by addition of 0.1 ml of 1N NaOH. After addition of alkali, ^{32}P-T7 phage was added. *b*, ^{3}H and ^{32}P-labelled phage were lysed in 1 ml of lysis buffer made alkaline by addition of 0.1 ml of 1N NaOH. Alkaline sucrose gradients were formed, centrifuged, fractionated and counted as described in the legend to Fig. 1. ●, ^{3}H-T7; ○, ^{32}P-T7.

A preliminary experiment indicates that a chromatin-bound nuclease activated by Pronase is unlikely, since DNA lysed in alkali for 60 min, subsequently neutralised by dialysis, and treated with Pronase also exhibits primarily 26S DNA after a second alkaline lysis. Similarly treated DNA not digested with Pronase is rapidly sedimenting. It is unlikely that a chromatin-bound nuclease would survive the initial alkaline lysis.

RNA linkers have been observed in mitochondrial DNA[11], and we cannot, at present, exclude the possibility of a modified alkali-resistant RNA linker or an RNA linker protected from alkali by protein.

A protein or peptide linker should be affected by Pronase digestion. The possibility of protein linkers in eukaryotic chromatin has been indicated by the presence of associated, cosedimenting peptide sequences in purified DNA[12]. But the early discussions of protein linkers in DNA often assumed such linkers were "in register" on the anti-parallel strands[13]. Such "in register" linkers are unlikely since double-stranded DNA is insensitive to proteolysis[1]. Pronase-treated EAT cell DNA sedimented in neutral conditions is also extremely large if precautions are taken to avoid shear and denaturing conditions. It should be noted, however, that a protein linker has been observed in adenovirus DNA[14] and is apparently related to its replication.

Since stationary phase cells have been reported to have fragmented DNA of the size observed here[15], it is important to note that the EAT cells had a labelling index of 28±1%. Results similar to those described here have also been obtained with the Karzel strain[16] of EAT cells in exponential growth in tissue culture, using a lower cell density in the lysate.

Using similar lysing conditions with CHO (ref. 3) or mouse L cells[17], others have observed a single-strand subunit of 60×10^6 or 45×10^6 daltons, which is larger than the pieces observed here but smaller than subunits observed by simple alkaline lysis[3–8]. Moreover, Taylor *et al.*[18,19] have observed the double-strand equivalent of the single-stranded 26S DNA in CHO cells. These double-stranded fragments seemed to be enriched in newly-replicated DNA.

Many authors[3–8] have used lysis of eukaryotic cells in alkali to measure the size of long single-stranded DNA. The data presented here indicate that the single-stranded 'DNA' may be composed of smaller subunits linked by alkali stabile linkers which can be removed or made alkali labile by treatment with Pronase. The 26S subunits produced do not seem to be a result of soluble nuclease activity during digestion with Pronase.

We thank K. Geider and H. Kaerner for their assistance in preparing phage markers. This work was supported by the German Cancer Research Centre while H.V.H. was a visiting scientist at the Institute for Cell Research.

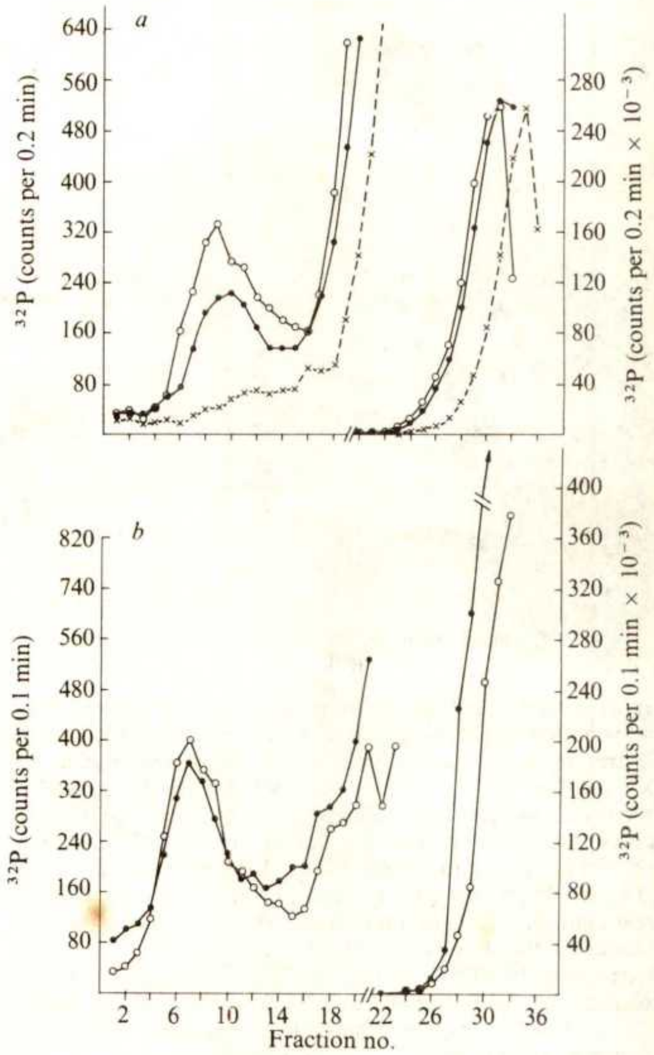
Intact 3′ end of 16S rRNA is not required for specific mRNA binding

INITIATION of protein synthesis in bacteria requires that ribosomes bind to specific regions of messenger RNA (mRNA) in a complex which also contains fMet-tRNA, GTP, initiation factors[1] and involves the ribosomal proteins S1 and S12 (refs 2–5). Shine and Dalgarno proposed a mechanism for initiation of protein synthesis in which certain purine-rich nucleotide sequences near the initiator codon of prokaryotic messages were postulated to form base pairs with the nucleotide sequence (5′) ACCUCCUUA(3′) near the 3′ end of the 16S ribosomal RNA[6,7]. The formation, *in vitro*, of a complex between the 3′ end of the 16S rRNA from *Escherichia coli* ribosomes and the initiator

Fig. 1 Sucrose density gradient analysis of initiation complexes after RNase digestion. Binding reactions were carried out in conditions described by Steitz[9], at 37 °C in 0.1 ml of a solution containing 0.1 M Tris-HCl (*p*H 7.4), 0.05 M NH$_4$Cl; 0.005 M magnesium acetate (RBS buffer); 0.001 M GTP; 3–5 μg of purified *N*-formylmethionyl tRNA from *E. coli*; (α-^{32}P-UTP)-labelled f1 or φX174 mRNA synthesised *in vitro*, as described by Pieczenik, *et al.*[10], specific activity $\sim 2\times10^8$ counts μg^{-1}; 4.5 A_{260} of *E. coli* ribosomes, and 37.5 μg phage f2 RNA. The binding reactions were done in conditions of limiting ribosomes. This was determined by a set of binding reactions (not shown) with constant amounts of ribosomes and increasing amounts of unlabelled f2 RNA, as competitor for a constant amount of radioactively labelled mRNA. The ribosomes were isolated from S-30 extracts prepared as described by Webster, *et al.*[26] 0.225 ml of S-30 was incubated at 37 °C with TM buffer (50 mM Tris-HCl, *p*H 7.6; 30 mM NH$_3$Cl; 10 mM Mg acetate) (control) or with 0.06 ml of a solution of colicin E3, 2.2 mg ml^{-1}. At the end of 20 min, 18 μg of colicin E3 immunity protein[17] in TM buffer were added to terminate the action of the colicin. Aliquots were then removed to measure the capacity of the treated ribosomes to carry out f2 RNA-directed protein synthesis *in vitro*[17]. Debris was removed from the samples by centrifugation at 12,500 r.p.m. for 15 min and then the ribosomes were pelleted by centrifugation for 3.5 h at 35,000 r.p.m. in the SW50.1 rotor. The supernatants were discarded and the ribosomal pellets suspended in TM buffer to give a final concentration of approximately 1,000 A_{223} ml^{-1} for the binding reactions. Binding reactions were carried out for 12 min at 37 °C, cooled, and then pancreatic ribonuclease (Worthington) was added to give a final concentration of 5.5 μg ml^{-1}. Reactions were warmed at 37 °C for 30 s, incubated at room temperature for 20 min, cooled on ice, layered on to 5 ml 5–20% sucrose gradients in RBS buffer, centrifuged for 2.25 h at 37,000 r.p.m. in the SW50.1 rotor of the Beckman Model L2-65B ultracentrifuge, at 5 °C. Fractions of 2 drops each were collected through a needle at the bottom of the gradients and their Cerenkov radiation monitored. *a*, Binding of ribosomes to ^{32}P-f1 mRNA. ●, control ribosomes: ○, colicin E3-treated ribosomes; ×, binding reaction done in the absence of fMet-tRNA. *b*, Binding of ribosomes to ^{32}P-αX174 mRNA. ●, control ribosomes; ○, colicin E3-treated ribosomes.



region of phage R17 A-protein mRNA has been demonstrated[8]. This binding supports the involvement of such base pairing in the binding of mRNA to ribosomes, at least for this message.

The ability of ribosomes to protect regions of mRNA of specific sequence from nuclease digestion is considered to be a general measure of specific binding between ribosomes and mRNA[9], and depends on the presence of fMet-tRNA[9] and yields specific sequences on fingerprint analysis[9].

Colicin E3 induces a specific break 49 nucleotides from the 3′ end of the 16S rRNA in the 30S ribosomal subunit, but does not lead to the loss of the cleavage product from the ribosome[11–15]. The question arose, given the Shine and Dalgarno hypothesis[6], as to whether colicin treatment of ribosomes would affect the mRNA binding reaction. We report here that treatment of *E. coli* ribosomes with colicin E3 had no significant effect on their ability to protect phage f1 or φX174 mRNA initiation sequences from RNase digestion (Fig. 1). Furthermore, fingerprinting analysis of the protected RNA suggests that the complexity and specificity of the protected RNA remain largely unchanged following colicin treatment (Fig. 2). The amount of radioactively labelled mRNA protected from RNase digestion was, in fact, consistently higher when colicin-treated ribosomes were used than when untreated ribosomes were used in the protection assay (Fig. 1).

As shown in Fig. 1, the colicin treatment had lowered the ability of the treated ribosomes to carry out f2 RNA-directed protein synthesis by 75%. Even when colicin treatment was carried out in the presence of f2 mRNA and supernatant factors, a procedure which inactivates ribosomes to greater than 90% (ref. 16), little or no decrease in their ability to protect initiation sequences was observed (data not shown).

Ribosomes treated in the presence of colicin E3 immunity protein, which prevents the action of colicin E3 *in vitro*[17], behaved like untreated, control ribosomes (data not shown).

To determine whether there were any differences in the sequences protected by treated ribosomes, the peaks of ribosome-bound mRNA from the reactions shown in Fig. 1 were collected, separated from the ribosomes, and subjected to two-dimensional T$_1$ fingerprint analysis, as described by Pieczenik, *et al.*[10]. The results for the f1 mRNA are shown in Fig. 2. The f1 mRNA protected by untreated and E3-treated ribosomes give similar fingerprints. There may be some minor differences in the amounts of some of the sequences protected, as measured by the intensity of the spots. No sequences were, however, completely eliminated, nor did any new spots appear as a result of the colicin treatment. The ribosome-protected fragments from φX174 mRNA (Fig. 1) were also subjected to two-dimensional T$_1$ fingerprint analysis, and here again the sequences protected by colicin-treated ribosomes did not differ appreciably from those protected by the untreated ribosomes (Ravetch, Robertson and Model, unpublished). Thus we infer that there was no change in the specific mRNA sequences protected by those ribosomes.

The three ribosome binding sites of phage f1 mRNA have been sequenced[10]. Their sequences have the potential to form base-pair interactions with the polypyrimidine stretch near the 3′ end of the 16S rRNA. These potential structures are shown in Fig. 3. Although the number of base pairs differ, the free energies estimated by using the method of Tinoco, *et al.*[18] are comparable. These potential structures can be expected to have similar stabilities.

Although Tai and Davis[19], Tai[20], and Konisky[21] have

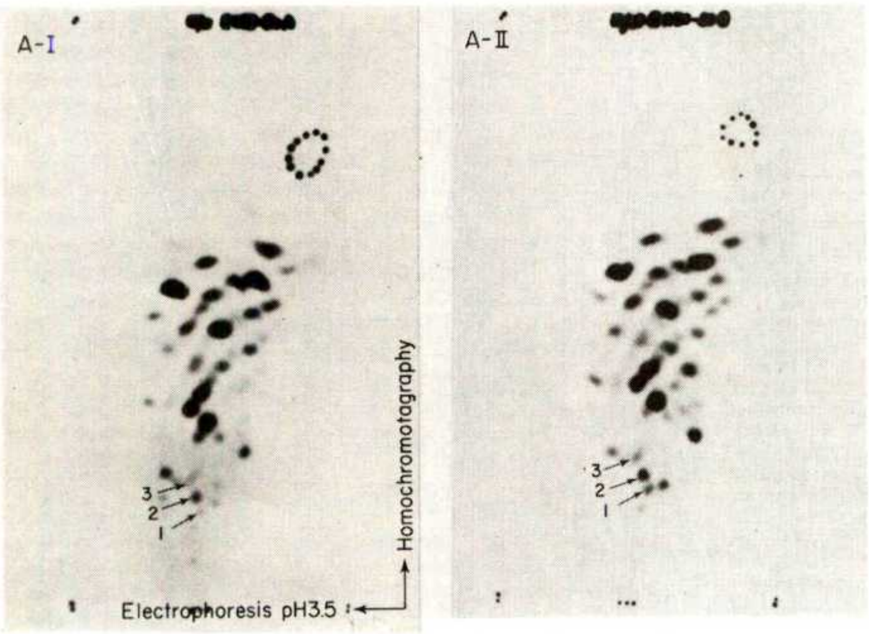


Fig. 2 T_1 fingerprint analysis of ribosome-protected fragments from ^{32}P-labelled f1 mRNA for untreated (*A*-I) and colicine E3-treated (*A*-II) ribosomes. Two-dimensional fingerprint analysis was carried out as described previously[27]. Arrows indicate the major T_1 oligonucleotides of the three ribosome binding sites of f1 mRNA[10]. The origins of chromatography were uniformly at the position marked in Fig. *A*-I.

reported that colicin E3 inhibits initiation of protein synthesis on natural messages, others have reported that colicin E3 treatment does not inhibit (AUG)-dependent binding of fMet-tRNA[22] or poly(U) or MS2 RNA[23] to 30S subunits. Our results indicate that colicin E3-induced cleavage of ribosomes does not prevent the formation of 70S initiation complexes on natural messages, so that block which colicin E3 causes in protein synthesis must be at a later step. Colicin treatment in the conditions used here does not result in release of the 3′ terminal RNA fragments from the 30S ribosomal subunit[13,15], so that while an intact 16S RNA is not required for initiation complex formation, the presence of the cleavage fragment may still be needed for proper alignment of the message on the ribosome.

Baan *et al.*[24] have found that cloacin DF13, which has a mode of action virtually identical to colicin E3 (ref. 25), does not appreciably inhibit the formation of an initiation complex between ribosomes and MS2 mRNA in the absence of IF-1. They find that cleavage by the cloacin causes a reduction in the rate, but not the final amount of initiation complex formed, and they postulate improper functioning of IF-1. The initiation complexes formed were fully reactive with puromycin. They also observed a reduced ability of the second aminoacyl tRNA (alanyl-tRNA for the case of MS2 RNA) to bind, but such alanyl-tRNA as did bind was able to participate in dipeptide formation. Their observations are in accord with our results. Our data and those described above[24], therefore, bear on the question as to whether colicin E3 treatment of ribosomes inhibits the initiation or elongation steps of protein synthesis. Since the peptidyl transferase has previously been shown to be undamaged by colicin E3 treatment[22], and dipeptide formation is not blocked[24], the lesion induced by colicin E3 is most likely in the translocation step of protein synthesis.

Fig. 3 Potential base-pair interactions between f1 mRNA ribosome binding sites and the 3′ end of 16S ribosomal RNA. Sequence determination was described by Pieczenik *et al.*[10]. Free energy estimates were made using the method of Tinoco *et al.*[18].

Our results suggest that cleavage of the 3′ end of the 16S ribosomal RNA does not affect the specificity of the binding of ribosomes to f1 or φX174 mRA. An intact 3′ end of the 16S rRNA is apparently not essential to confer stability and specificity on mRNA binding. In fact, perhaps the greater flexibility of the 16S rRNA allowed by its cleavage by colicin E3 may be responsible for the enhanced level of binding observed after colicin E3 treatment (Fig. 1). The failure of colicin E3-treated ribosomes to function in f2 mRNA-directed protein synthesis implies, however, that an intact 16S rRNA is required for translocation to occur on the ribosomes.

We thank Peter Model for his encouragement and helpful advice and for providing us with radioactively labelled mRNA. We also thank Norton Zinder, Hugh Robertson and Joan Steitz for helpful discussions. This research was supported in part by grants from the NSF to N. D. Zinder and H. D. Robertson.

Occurrence of *trans*-ribosylzeatin in *Agrobacterium tumefaciens* tRNA

THE cytokinin-active N-6-isoprenoid-substituted purine nucleosides have wide distribution as minor components of the tRNA of animals, bacteria and plants. Skoog, Hall and others (refs in ref, 1) have shown that there are three classes of cytokinin nucleosides, and that one member of each predominates in the tRNA of organisms from each kingdom. Thus, animal tRNA contains 6-(3-methylbut-2-enylamino)-9-β-D-ribofuranosyl purine[2] (iPA); whereas in bacterial tRNA, the purine ring is thiomethylated and the predominant cytokinin-active nucleoside is 6-(3-methylbut-2-enylamino)-2-methylthio-9-β-D-ribofuranosyl purine[3] (ms-iPA). In plants, the isoprenoid side chain is hydroxylated and the predominant cytokinin-active nucleoside is 6-(4-hydroxy-3-methylbut-2-enylamino)-9-β-D-ribofuranosyl purine[4] (zeatin riboside, ZR). Minor amounts of 2-methylthio zeatin riboside (ms-ZR) are also present[5]. But the distribution of these nucleosides may not be quite so clearcut. The plant pathogenic prokaryote *Corynebacterium fascians* has been shown[6] to release *cis*-zeatin into the culture medium. Other evidence[7] suggests that *Pseudomonas aeruginosa* tRNA contains ms-ZR. It may be that some prokaryotes have acquired the ability to hydroxylate the isoprenoid side chain and that zeatin and its derivatives are not restricted to plants. We have now examined the cytokinin-active nucleosides from the tRNA of *Agrobacterium tumefaciens*, the causative organism of plant crown gall disease. Besides the expected ms-iPA and small amount of iPA, *trans*-ZR was present in significant amounts.

Four strains of *A. tumefaciens* were examined. Two strains, IIBV7 and C-58, are virulent and have been shown to harbour a large plasmid which is associated in some way with virulence[8]. The other two strains IIBNV6 and NT1, are avirulent and do not contain the plasmid. Strains C-58 and NT1 are very closely related in that NT1 is derived from C-58 by heat treatment which causes elimination of the plasmid with concurrent loss of virulence.

Cells were grown to late log phase on rich medium[9]. The tRNA was isolated by Kirby's procedure, purified by extraction with sodium acetate, and freed from traces of DNA by treatment with *m*-cresol-sodium benzoate[10]. Cytokinin-active nucleosides were isolated by alkaline hydrolysis and dephosphorylation with *E. coli* alkaline phosphatase and were extracted into 1-butanol. The butanol-soluble fraction was subjected to high pressure reversed-phase chromatography (HPLC) on octadecyl-substituted silica and cytokinin activity was detected in the column eluate by means of the cucumber cotyledon bioassay of Fletcher and McCullagh[11]. Figure 1 shows an HPLC profile obtained for IIBNV6 tRNA hydrolysate.

Standard cytokinins eluted from the column in decreasing order of polarity. The most polar, zeatin riboside, eluted before zeatin which in turn eluted before iPA, iP and ms-iPA. The hydrolysate contained five regions where cytokinin activity was significantly above baseline. The first two peaks of activity eluted at 16–24 ml and 32–36 ml and contained substances more polar than zeatin riboside. They have not been characterised further. The three major peaks (eluting at 40–48 ml, 56–64 ml and 68–76 ml) coeluted with authentic ZR, iPA and ms-iPA. To establish their identity, the appropriate fractions were pooled and the nucleosides were converted into their permethyl[12] or trimethylsilyl (TMS) ethers[13] which were then examined by gas chromatography–mass spectroscopy (GC–MS).

The fraction with mobility identical to iPA gave, when permethylated, a derivative which exhibited a single peak on gas chromatography identical in retention time to permethylated iPA. Examination of the mass spectrum of this peak showed it to possess a molecular ion $M^{+\bullet} = 391$ and major fragment ions at 376 (loss of $CH_3^{\bullet}$), 348 (loss of $C_3H_7^{\bullet}$ with ring closure of the isoprenoid side chain onto the purine N-1 position), 217 (fission of the base and ribose with transfer of a hydrogen atom to give $BH^{+\bullet}$), 202 (loss of $CH_3^{\bullet}$ from $BH)^{+\bullet}$, and 174 (loss of C_3H_7 from $BH^{+\bullet}$). The ion at $m/e = 45$ was characteristic of the fragment ion $CH_3OCH_2^{+}$ arising from the 6 position of ribose[12]. Studies with deuterated methyl iodide confirmed the fragmentation assignments and the presence of four methyl groups within the molecule. Its spectrum was identical with an authentic sample of tetramethyl iPA. Von Minden and McCloskey[15] have reported an identical spectrum and peak assignments for tetramethyl iPA.

Similarly, the HPLC fraction corresponding in mobility to ms-iPA gave on permethylation a product whose GC retention

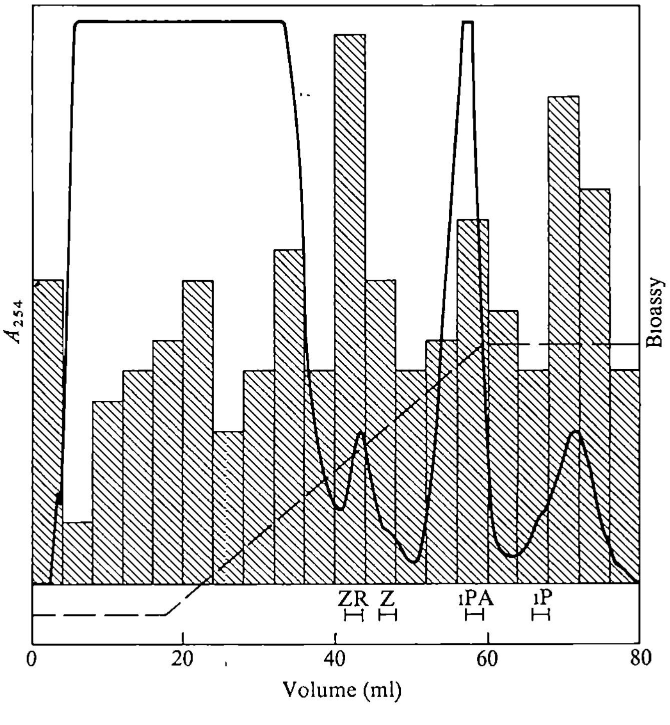

Fig. 1 High pressure liquid chromatography of *A. tumefaciens* (strain IIBNV6) tRNA hydrolysate. Purified tRNA (~2,000 A_{260} U from organisms grown in rich medium to late log phase was hydrolysed with 0.3 M KOH under nitrogen at 37 °C for 24 h, treated with bacterial alkaline phosphatase (Sigma, 150 U ml^{-1}) at *p*H 8.8 in the presence of 10 mM $MgCl_2$ at 37 °C for 16 h and extracted with 1-butanol. The extract was evaporated, taken up in a minimum volume of 5% ethanol, *p*H 3.5, and applied to a 0.3 × 60-cm column of octadecyl-substituted silica (C_{18}/Porasil B, 37-75 μm, Waters Associates) previously equilibrated with 0.02 M ammonium acetate buffer, *p*H 3.5, containing 5% ethanol. The column was eluted with a linearly increasing gradient of ethanol (5–50%) over 40 ml at a flow rate of 4 ml min^{-1}. Fractions (4 ml) were collected, lyophilised and assayed for the presence of cytokinin-active nucleosides by the procedure of Fletcher and McCullagh[11]. - - - -, Ethanol gradient; ——, A_{254}. Hatching shows cytokinin activity (arbitrary units). Cytokinin standards eluted at the positions indicated.

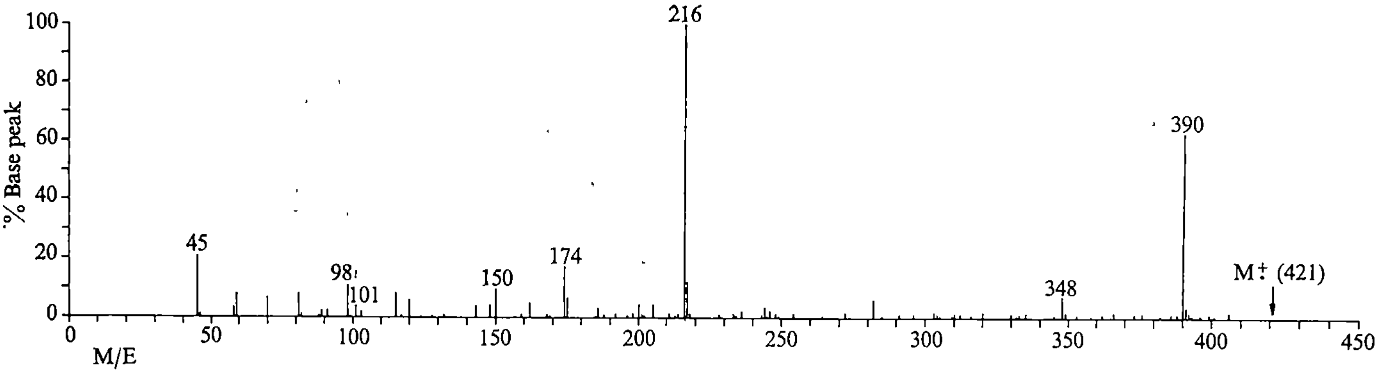

Fig. 2 Mass spectrum of permethylated nucleoside from *A. tumefaciens* tRNA HPLC fractions containing cytokinin-active material with the same mobility as ZR (Fig. 1 fractions 40–48 ml) were evaporated and the residue was permethylated by reaction with methyl iodide in the presence of a fivefold excess of dimethyl-sulphinyl anion in dimethylsulphoxide[12]. The reaction mixture was diluted with water, the permethyl ethers were extracted into chloroform and analysed by GC–MS GC conditions were: glass column; 3% Dexsil on Anachrom A, 28 cm; He carrier, flow 15 ml min^{-1}; 150 °C for 3 min, then 8 °C min^{-1} to 350 °C. The column effluent was admitted to the source of a Varian CH7 magnetic sector spectrometer through a single stage glass jet separator at 240 °C. Spectra were recorded continuously (at 70 eV) during the chromatographic run and processed, stored, and analysed on an accompanying data system (System Industries; System 150).

time and mass spectrum were identical with those of authentic tetramethyl ms-IPA. $\mathrm{M}^{+}_{\bullet} = 437$, fragment ions at *m/e* 423 ($-\mathrm{CH}_3^\bullet$), 394 ($-\mathrm{C_3H_7^\bullet}$ and side chain cyclisation), 263 ($\mathrm{BH}^{+}_{\bullet}$), 248 ($\mathrm{BH}^{+}_{\bullet}-\mathrm{CH}^\bullet$), and 220 ($-\mathrm{C_3H_7^\bullet}$ from $\mathrm{BH}^{+}_{\bullet}$). As expected, all major fragments derived from the adenine nucleus were shifted +46 mass units from the corresponding iPA fragments due to the presence of the thiomethyl group at the 2 position of the purine ring.

The HPLC fraction with mobility equal to that of ZR gave on permethylation a product which GC revealed to have two major components. The first gave a mass spectrum identical to authentic permethylated dimethyl adenosine and was not examined further. The second, whose spectrum is shown in Fig. 2 had major fragment ions present at 390 and 216, and a small molecular ion at 421. Its spectrum was identical to that of authentic pentamethyl ZR. Probable peak assignments (confirmed by deuteromethylation) are $\mathrm{M}^{+}_{\bullet} = 421$; 390, loss of $\mathrm{OCH}_3^\bullet$; 216, loss of $\mathrm{OCH}_3^\bullet$ from $\mathrm{BH}^{+}_{\bullet}$; 174, loss of $\mathrm{C_3H_7^\bullet}$ from $\mathrm{BH}^{+}_{\bullet}$ (cyclisation). Loss of the allylic methyl ether fragment ($\mathrm{OCH}_3^\bullet$) was favoured over the loss of $\mathrm{C_3H_7^\bullet}$ and subsequent ring closure found in iPA and ms-iPA. Details of these spectra will be published elsewhere.

Examination of the trimethylsilyl ethers derived from this HPLC fraction confirmed the presence of ZR. Gas liquid chromatography on Dexsil 300 can resolve *cis*-(TMS)$_4$ZR from *trans*-(TMS)$_4$ZR (ref. 13). The sample of (TMS)$_4$ZR from IIBNV6 hydrolysate had a retention time of 18.2 min, identical to that of authentic *trans*-(TMS)$_4$ZR. The *cis*-isomer in identical conditions had $R_t = 17.8$ min.

We conclude, therefore, that *A. tumefaciens* strain IIBNV6 tRNA contains, besides the iPA and ms-iPA expected for prokaryotes, the hydroxylated cytokinin nucleoside *trans*-ZR, the *cis*-isomer of which is normally found in plant tRNA. Other strains of *A. tumefaciens* also contained *trans*-ZR although at lower levels than IIBNV6. Visual estimates (from HPLC and GC traces) suggested that *trans*-ZR made up about 30% of the total cytokinin-active nucleosides in IIBNV6 tRNA. In the related virulent strain IIBV7 the level was comparable. In C-58 and NT1, however, the level was much lower (5–10% of the total) and a fourth active component was present. It had a mobility on HPLC intermediate between ZR and iPA, and has yet to be identified. Differences in cytokinin content between strains did not appear to correlate with virulence and may reflect the nutritional and growth status of the culture, as is the case for the modified nucleoside "Q" in BALB/3T3 tRNA (ref. 16).

The unequivocal demonstration of zeatin riboside in the tRNA of *A. tumefaciens* confirms evidence developed by others that some prokaryotes may be able to hydroxylate the isoprenoid sidechain of cytokinins. Cheryayil[7] used ^{35}S to demonstrate the probable presence of methylthiozeatinriboside in *Pseudomonas aeruginosa* tRNA while Torrey[17] has isolated a cytokinin from *Rhizobium* tRNA which, although not identified conclusively, has the chromatographic properties expected for zeatin riboside. In contrast, no evidence has been published for the presence of zeatin riboside in *E. coli*[3] or *Staphylococcus epidermidis*[18] tRNA. The common factor which unites those prokaryotes which can hydroxylate the isoprenoid side chain is their association with plants, either as pathogens or symbionts. It remains to be seen whether this factor has a necessary role in their association with the host plant or if it is merely fortuitous.

Scrotal asymmetry: an appendix

TESTICULAR asymmetry, as McManus has shown[1], was a not uncommon feature of Greek and Roman sculpture, the ancient artist, always attentive to nature, seems to have noticed that the right-hand testis is usually the higher, and inferred (apparently incorrectly) that the other ought therefore to be the larger.

For the historian, however, two questions still remain to be answered. when did the Greeks first discover this peculiarity, and how consistently did they observe it in the early stages of their art? McManus's data, coming as it does from museums in Italy, must of necessity be confined almost entirely to sculpture of the classical period onward (that is, from the fifth century BC to Roman times). Since the preceding century, from the birth of monumental sculpture in Greece around 600 BC, was an era of rapid development in both style and understanding of the the anatomy of the human body, it may be worthwhile to supplement his survey with a look at the 80 kouroi, or standing archaic youths, where this feature is preserved intact. I use Richter's typology[2], based on minute anatomical analyses and generally accepted today, and Harrison's revised chronology[3], which puts the beginning of the series at around 600 BC and its end just before 480 BC, the data of the Persian invasion and sack of Athens. The results (Tables 1–3) can be summarised as follows.

As might be expected, the early groups (Sounion and Orchomenos–Thera Table 1) show a propensity to equalise the testes in both height and size (or, occasionally, to model them as one; this is particularly the case with statuettes, and continues, though to a diminishing extent, down to the end of the Archaic period· see ref. 2, nos 13, 22, 26, and so on· in such cases I record the two as "equal") though even at this early date the right is already higher than the left in about two-fifths of the statues sampled In these and the six statues in which the opposite case obtains, the distribution of size seems to be more-or-less random.

By the middle of the century (Tenea–Volomandra and Melos groups: Table 2), the right testis is the higher in a majority of cases, though in only half of these is the other the larger: the tendency to equalise the testes in size is still dominant.

In the final period (Anavyssos–Ptoon 12 and Ptoon 20 groups: Table 3) the classical scheme is already established. Again, the right testis is usually the higher (though about a quarter of all sculptors, intent on symmetry, still persist in making the two equal in height and size—a practice that is, apparently, to continue), (see ref. 1, Table 1), and the left is now regularly the larger. Significantly, in no case now is the higher testis the larger: Greek sculptors seem to have bowed to the dictates of common sense, as opposed to science, even in the adolescence of their art.

Specificity of transfer factor

THE letter by Salaman and Valdimarsson[1] is an important step forward in the understanding of the problem of whether the activities of dialysable transfer factor (TFd) are specific or not. They admit that two substances may be involved in the effects of dialysable leukocyte extracts (DLE)—one adjuvant-like material and another specific substance (that is, TFd). In fact, until recently, reports on the effects of TFd dealt with the effects of crude preparations of DLE or roughly purified fractions thereof.

There remains, however, one important point which, although suggested by Salaman and Valdimarsson when they reported that nonspecific effects are more evident in tuberculin-positive than tuberculin-negative individuals, is generally overlooked and which contributes to the confusion in this area of research. It was formerly claimed by medical practitioners that there were no "diseases", only "patients". In other words, a given disease may have a different clinical course, before and/or during treatment, in different patients. This raises the question of recipient peculiarity or, in the case of DLE, "recipient specificity" The effects of DLE are also surely dependent on the specific characteristics of the recipient; for example, it can often be observed that, no matter how strongly positive a leukocyte donor is to a given set of antigens by skin testing, the DLE preparation obtained induces positive skin-test reactivity only to one of the antigens in some recipients and only to another in other recipients, and some show increased lymphocyte DNA synthesis in the presence of antigens *in vitro* whereas others do not[2-4]. Therefore, investigators who intend to study the effects of DLE should consider (at least until it is clearly demonstrated to the contrary) that they are probably dealing not only with an adjuvant-like material and a donor-specific substance (TFd) but also, in both cases, with recipient specificity, which can mask the effects of these substances—if indeed they exist.

Permeability of blood–cerebrospinal fluid barrier during foetal and perinatal life

THE HIGH level of protein in early foetal cerebrospinal fluid (CSF) from human abortion material reported by Adinolfi *et al.*[1] is important confirmation of results obtained from earlier work on human[2] and animal foetal CSF[3,4]. Part of the high concentration of protein, however, may have been due to hypercapnia, since foetuses obtained from abortions are likely to be asphyxiated by the time CSF samples are taken. Hypercapnia increases the penetration of albumin[5] and other lipid insoluble molecules[6] from blood into CSF. This is suggested by the very high concentration of CSF protein in the 40-week foetus, compared with normal term newborn infant[7,8]. Adinolfi *et al.* suggest that their findings confirm the proposition suggested previously by several authors[9] that the blood–brain and blood–CSF barriers to protein are poorly developed in foetal and perinatal life. An alternative explanation for the high level of protein in foetal CSF, however, is that certain plasma proteins may be transported into foetal CSF at an early stage in brain development[4,10]. This was based on electron microscopical evidence that the tight junctions (which form the barrier to protein in adult brain[11]) of cerebral endothelial and choroid plexus epithelial cells are already well developed at a stage when the CSF protein level is very high. There is also evidence[4] from studies of isotopically-labelled protein that certain plasma proteins (for example, transferrin) may be transported into the CSF of early foetal brain, but not later in development. This finding has recently been supported by studies using human serum proteins detected by immunoassay[10] which showed that both transferrin (molecular weight 74,000) and α foetoprotein (molecular weight 64,000) penetrated from blood into CSF to a much greater extent than albumin (molecular weight 69,000) in 60-d-old foetal sheep—a stage when the CSF contained about 350 mg per 100 ml total protein (term is 147 d).

ADINOLFI ET AL. REPLY—We thank Saunders *et al.*[1] for calling our attention to their work[2], and as yet unpublished results[3]. Regarding the effect of hypercapnia, we do not discount it as a possible factor influencing the levels of plasma proteins in CSF. Saunders *et al.* must be aware of the difficulties of working with human foetal material; it is after all post-mortem material. We stated in our paper[4] that the results were based on a very selected group of foetuses. Many samples of foetal CSF were discarded because of contamination with blood and almost all foetuses obtained by termination with prostaglandin could not be used.

We acknowledge that the levels of some proteins were higher than expected in the 40-week-old foetus; whether this was due to hypercapnia or other factors we are unable to say. This does not, however, alter our conclusion that the permeability of the blood–CSF barrier is incomplete during foetal life.

Recent evidence, based on the estimations of the levels of specific plasma proteins such as albumin, α-foetoprotein, IgG and prealbumin in serum and CSF from the same foetus, suggests that the mechanisms of transfer vary among different proteins. Thus, for example, whereas the percentage of prealbumin in CSF, as compared with blood, varied between 40 and 70, the levels of other proteins varied from ~ 5 to 20%. These variations were found to be related to the ages of the foetuses.

In our paper[4] we merely presented our observations; at this stage of our work it seemed to be premature to advance any hypothesis on the mechanisms of transfer of plasma proteins from blood into CSF in human foetuses.

Mr D. Allen, taking as his text Emerson's comment that once the facts of natural history are married to human history they become full of life, has attempted the first social account of British natural history. His survey begins with the early seventeenth century when naturalists began exchanging observations and discoveries, occasionally coming together on field excursions such as the 'herborisings' organised by the Society of Apothecaries. Mr Allen has not been able to add much to the little already known about the development of natural history studies in the seventeenth and early eighteenth centuries. By the middle of the eighteenth century the study of natural history was beginning to be accepted as an essential part of a liberal education and this is where Mr Allen's narrative really gets under way. As he points out, natural history attained respectability largely through the researches and teaching of the great Swedish naturalist, Carl Linnaeus. Botany in particular was caught up in the romantic movement which swept Europe. Jean-Jacques Rousseau, a seminal figure in this movement and no mean botanist himself, urged the study of botany as a way of communicating with the essential spirit of Nature.

A great deal of the book is devoted to an examination of the Victorian period when nature study became a popular pastime and was responsible for the many shell pictures and albums of pressed flowers which still survive It was with evident satisfaction that Charles Kingsley noted that "books of Natural History are finding their way more and more into drawing rooms and school-rooms, and exciting greater thirst for a knowledge which even 20 years ago, was considered superfluous for all but the professional student."

Serious research was fostered by the formation of societies such as the Aurelian Society in 1762, the Linnean Society in 1788, the Horticultural Society of London in 1804 and the Zoological Society of London in 1826. But as Mr Allen convincingly demonstrates, nowhere was enthusiasm and dedication more evident than in the humble gatherings of workingmen naturalists. Such was James Bolton of Halifax who not only taught himself botany but also mastered drawing and engraving to illustrate his books. Stamina and single-mindedness were the sterling qualities so many of these naturalists had in abundance. As a young man William MacGillivray walked 800 miles from Scotland just to see the fine bird collection in the British Museum

Philip Henry Gosse was so absorbed in his studies that his diary recorded his son's birth almost as a casual afterthought: "Received green swallow from Jamaica E[liza] delivered of a son" Country parsons stagnating in a cultural desert frequently sought refuge in the world of Nature One thinks of Gilbert White's meticulous observations at Selborne, M. J. Berkeley's important contributions to mycology, S R. Hole's delight in roses and the popularisation of natural history in the spate of books by F. O. Morris and J. G. Wood.

Entomology and botany have always been considered an appropriate female occupation, while the collecting of shells was once recommended because they "are so brightly clean, so ornamental to a boudoir " But women's involvement was not always through a gentle pursuit of culture In the nineteenth century Mrs Gatty and Mrs Griffiths made systematic collections of algae and Mary Anning discovered the first nearly complete skeleton of a Plesiosaurus in the Liassic cliffs near Lyme Regis.

Children were introduced to the marvels and mysteries of Nature in books such as E. and S. M. Fitton's *Conversations on Botany* (1817), set out in the familiar form of a catechism between child and parent Mr Allen only briefly touches on the passion for disseminating knowledge common to all Victorian reformers for whom education was a means to moral improvement. Religious bodies such as the Society for Promoting Christian Knowledge and the Religious Tract Society sponsored a number of primers of botany and zoology. Probably the limitations of space prevented Mr Allen from giving due weight to the important role of some commercial publishers, notably Richard Groombridge and Lovell Reeve, in promoting the production of inexpensive natural history books.

With the advancement of serious research in the universities and the emergence of new disciplines such as ecology, the gap between the professional and the amateur has inevitably widened. Nevertheless, the appeal of natural history has always been the scope it affords the amateur. Mr Allen is particularly good in explaining its increasing popularity during the present century, due in part, he maintains, to the rediscovery of the countryside by bicycle and motor-car. It is now no longer a matter for surprise when books like the Rev. W Keble Martin's *Concise British Flora in Colour* (1965) become instant bestsellers.

Mr Allen is a keen field botanist and it is therefore understandable that he gives a fuller treatment to botany than to zoology. Nonetheless he has unearthed much new or forgotten material from a vast assortment of printed and manuscript sources to compile this fascinating story of the discovery of Nature, and of the men and women who devoted their lives to its study. ☐

Mr Desmond is President of the UK Society for the Bibliography of Natural History.

Changing attitudes to wildlife

Nature in Trust· The History of Nature Conservation in Britain. By John Sheail. Pp. xiv+270. (Blackie· Glasgow and London, May 1976.) £5.95.

BEGINNING with a short survey of man's attitudes to nature preservation in the sixteenth century, Dr Sheail has traced, during the years for which he has the most complete documentation, the changing attitudes to the protection of wildlife. When naturalists first thought about protection they concentrated on preserving rare and distinctive plants and animals by means of legislation. Later, as the science of ecology developed, the concept of habitat protection prevailed. But having come to this conclusion land purchase was still not straightforward. The Society for the Promotion of Nature Reserves (SPNR) came into existence to promote the purchase of land by others, particularly the National Trust, and did not in those early days have money itself.

This book is a recital of facts gathered from the archives and files of voluntary bodies, particularly the SPNR and the Royal Society for the Protection of Birds (RSPB), and from governmental organisations. The bulk of the material relates to the first half of this century and chiefly between 1920 and 1950. It records the activities of the various committees which were set up, or which set themselves up, to examine the types of land which required protection, the different ways of acquiring it, the setting up of scientific authorities to manage the reserves, to undertake research, to advise governments and others on scientific problems.

At one point in the 1930s no one had clear ideas of what they wanted—what, for instance, the relationship should be between national parks and nature reserves, and the Government gave up trying to solve the problem. Although thought was given to environmental conservation in post-World War I reconstruction planning it fell to the voluntary bodies once again to persuade the Government to take action. Ultimately it was the committee headed by Sir Julian Huxley and the Nature Reserves Investigation Committee which began to produce the kind of recommendation that brought nature conservation out of the national park sphere of influence and that led to the establishment of the Nature Conservancy with its original triple function of reserve acquisition, research and scientific advice. Dr Sheail finally records briefly what has been happening since the 1950s.

I was enormously impressed by the facts that Dr Sheail has collected together and incorporated in his book. I wondered whether it would not have been possible to have digested them further or discussed their implication. He writes in an easy manner but at times I found it difficult to follow all the threads. The other point which rather worried me was that the book is described as *The History of Nature Conservation in Britain.* It is, however, more of a history of the development of the organisation side of nature conservation. There is no real discussion on the effect of writers, broadcasters and others who influenced the public to take a deeper interest in nature conservation, and various other activities.

I feel that the full history of nature conservation has still to be written. In saying this I am not denigrating what has been done in this volume. It is an enormous work of scholarship on one major aspect of the growth of conservation It is readable and will be of great value and interest. As a history it has lessons for the present.

Peter Conder

Peter Conder has recently retired as Director of the UK Royal Society for the Protection of Birds

Resistance in *Pseudomonas*

Resistance of Pseudomonas aeruginosa Edited by M R. W Brown. Pp. ix+335 (Wiley-Interscience: London and New York, September 1975.) £14.

THIS book is intended to define the problems associated with drug-resistant *Pseudomonas aeruginosa* from a number of different angles, in chapters written by different authors It suffers from the inevitable unevenness and repetition that result from diverse authorship in discussing a narrow field. The repetition is tiresome and it is clear that the editor did not exercise sufficient control over his team For example, chapters 4 and 5 present four electron micrographs in common, one of which is inverted in one chapter in relation to the other. The action of EDTA on *Pseudomonas* is mentioned too frequently. The chapter on antibiotic inactivation and its genetic basis carries some curious statements. For example, there is confusion between the spread of resistance plasmids and that of pathogenic bacterial clones carrying them. Intestinal bacteria other than *Pseudomonas* are very loosely referred to as "enterics" in this chapter. It also uses the term "evolution" imprecisely, and presents the puzzling statement that "there is good evidence that two clones of Gram-negative bacteria specifying resistance to gentamicin, including Pseudomonads, have become widespread in France". If there is more than one Pseudomonad there is no room in two clones for other genera And if there are one or more genera of bacteria other than Pseudomonads there is no room for a plurality of Pseudomonads.

The chapter on epidemiological typing presents details of a phage-typing scheme for *Pseudomonas* in such a way that no-one would realise that the principles and techniques it enunciates owe their origin and even terminology to the phage-typing schemes for *Salmonella typhi* and other salmonellae, none of which is mentioned It seems rather late in the day to publish a photograph of a surface spot titration of phage (Fig 1, p196), and Fig 2 on the same page is a poor illustration of a phage-typing result

Although valuable data are presented, there are faults, overstatements and omissions in all eight chapters of this book. All things considered it is of doubtful value at a price of £14.

E. S. Anderson

Red colobus

The Red Colobus Monkey. (Wildlife Behavior and Ecology.) By Thomas T. Struhsaker Pp xiv+311+37 plates (University of Chicago: Chicago and London, 1975.) £15.

ADEQUATE descriptions of the behaviour and ecology of rain forest mammals are rare, largely because difficult observations conditions impose severe restrictions on the scope and accuracy of the data which can be collected. Struhsaker's study of the red colobus is one of the few cases in which an observer has succeeded in producing a comprehensive survey both of social behaviour and feeding ecology, and represents a major achievement in this field

The four main chapters cover population dispersion, social behaviour (agonistic behaviour, grooming, sexual behaviour, mother–infant relationships and intragroup dispersion) and feeding ecology (food selection, ranging behaviour and interspecific relations). On each topic the author has been at pains to include both detailed qualitative descriptions of the behaviour patterns and, where relevant, quantitative material concerning their frequency.

The book is of particular interest because of the comparisons which it draws between the red colobus and the partially sympatric black-and-white colobus. The two species differ markedy in grouping patterns, red colobus living in large, multi-male troops which occupy extensive home-ranges—black-and-white in smaller and more cohesive single-male troops in defended territories The study shows that these differences are associated with variation in dietetic diversity and in the proportion of mature leaves in the diet at particular times of year.

Unlike its three precursors in the same series, this monograph is clearly aimed at specialists and is not easy to read, partly because the text relies heavily on 76 pages of tables published at the end of the volume.

T. H. Clutton-Brock

Chromosome configurations at meiosis

Meiotic Configurations. A Source of Information for Estimating Genetic Parameters. (Monographs on Theoretical and Applied Genetics, Vol. 1.) By J. Sybenga. Pp. x+251. (Springer: Berlin and New York, 1975.) DM68; $27.90.

DR SYBENGA gives an account of the different kinds of chromosome configurations encountered at meiosis; how they vary in response to change in genotype and environment, and to change in chromosome structure and number. He presents a critical survey of statistical methods by which the frequencies and distributions of the various kinds of configurations within and among individuals may be efficiently described and analysed. Many of the methods concern variation in configurations dependent on chiasma frequencies and distribution. Dr Sybenga is evidently sceptical of the ability of cytologists to score chiasmata with accuracy even in organisms, such as rye, with large chromosomes. The sceptisism, or modesty, embraces Dr Sybenga himself who, by way of caution, prefers to score the number of chromosome arms bound per bivalent rather than the number of chiasmata per arm I think Dr Sybenga is over modest. I know many who claim to score chiasmata with a very high degree of accuracy and thereby acquire more detailed information about the consequences of variation in chiasma formation!

To date, the emphasis in this field of investigation is of course on the *consequences* of variation in chiasma formation. We are still a long way from understanding the *mechanics* of chiasma formation or of other events at meiosis such as chromosome pairing. Many of the facts presented in this book provide clues as to why experiments seeking to elucidate the mechanisms are, to an unusual degree, difficult and inconclusive. Consider, for example, the question of establishing to what extent a structural change within a chromosome affects its ability to pair and form chiasmata with its homologous partner. We may introduce an alien chromosome segment, by transposition, and observe its effects. The trouble arises in interpreting these effects because the structural change is inevitably accompanied by a change in the chromosome genotype–that is in the content and arrangement of genes whose expression in itself affects pairing and chiasma formation independently of structural homology The effects of genotype and of structure are here, typically, confounded. Were we able to distinguish between them we would make some progress

Dr Sybenga, who has specialised in the study of meiosis, has produced a useful book, bursting with facts and figures which are presented with clarity and authority.

H. Rees

Life and death of microbes

The Survival of Vegetative Microbes. (Twenty-sixth Symposium of the Society for General Microbiology, April 1976.) Edited by T. R. G. Gray and J. R. Postgate. Pp. x+432. (Cambridge University: Cambridge and London, April 1976.) £12.

THIS year's Society of General Microbiology Symposium dealt with the subject of Survival of Vegetative Microbes and this book arises from it.

Death of microbes is a subject which impinges on many areas of microbiology but relatively little interest has been shown in such a 'vital' theme. This book brings together a number of chapters on this topic in an attempt to stimulate interest in this important area.

Professor Postgate introduces the subject in an admirably well written first chapter. Several of his comments on the problems of working in this field should be taken to heart by microbiologists, not least by some of the later contributors to the book. The next chapter by Professor Dawes is a classic review on the role of endogenous metabolism on survival of microbes.

The effect of other physiological stresses on survival are dealt with in a series of chapters on cold-shock and freezing, drying and aerosol stress, osmotic stress, ultraviolet and ionising radiation, light and heat. The next group of chapters deal with the survival of microbes in natural environments. Professor Morita's chapter deals with survival (in the sea, particularly) in conditions of extreme pressure. There then follows chapters on survival *in vivo* and in the soil. The last two contributions deal with the specific role of thymidine starvation, and the effect of chemicals on survival

Any book which is a collection of papers from different authors would be expected to vary in standard. This is indeed the case but the best are of a very high standard indeed. The two editors are to be congratulated in producing such a readable and informative book, and it is to be hoped that it will stimulate interest in this neglected area.

I strongly recommend that this book be general reading for all microbiologists so that they may appreciate the role that death as well as life may play in their areas of interest.

D. C. Ellwood

Books brief

An Introduction to Electromagnetic Fields. By R L. Ferrari Pp. xi+202 (Van Nostrand Reinhold· New York and London, September 1975) Cloth £7; Paperback £3.95

THIS is a slim volume which forms a welcome addition to the stock of available texts on electromagnetic fields Intended for an undergraduate audience, it uses extensively familiar examples of electric and magnetic phenomena to arrive at a clear physical understanding of field theory Comprehension is also considerably assisted by the liberal use of line drawings and illustrations Although the mathematical level of this book is comparable to others intended for the same audience, Ferrari's distinguishes itself by not forcing the mathematical pace, but rather by making full use of mathematics as a manipulative tool to assist in physical reasoning It is well written and eminently readable As a basis for a course of lectures, it would be desirable to supplement it by a well-chosen reading list of other books and articles, enabling the student to delve more deeply into areas of interest to him, and to pursue in some depths individual topics If its brevity can persuade a growing circle of engineering students to reach beyond a single volume to study a subject, rather than merely a book, it will have rendered great service.

P. Silvester

Methods of Optimisation By G R Walsh Pp x+200 (Wiley-Interscience: London, September 1975) Cloth £7.50; Paper £3.75.

THIS text essentially reviews a number of optimisation techniques, more from the algorithmic point of view than that of attempting a unified theoretical picture, but with enough theory given that the reader can establish a certain perspective In this spirit it runs through Lagrangian methods, non-linear programming (Kuhn–Tucker conditions, quadratic programming), search and gradient methods of optimisation (these sections quite thorough), some special techniques of constrained numerical optimisation, and a study of some special problems in dynamic programming In treating Lagrangian, Kuhn–Tucker and duality theory, the author regrettably never gets away from local versions of the results, and also misses their geometrical significance, which is so simplifying and illuminating As a medium-level no-nonsense introduction, however, the book is quite attractive.

P. Whittle

Animal Migration and Navigation By Philip Street Pp. 144. (David and Charles: Newton Abbot, London and Vancouver, March 1976) £4 95.

A POPULAR book such as this should ideally present a reasonably accurate account of the current state of knowledge in a readable and interesting style. Philip Street's book is certainly readable, but it is sadly inadequate as an account of modern work on migration and navigation. The author often digresses from the advertised subject matter—for example, to discuss infrared eyes in snakes, echolocation of prey in bats and communication in honeybees Much of the rest of the book consists of a catalogue of examples of long distance migrations in fish, marine mammals, amphibians, insects and birds. Although in his introduction, the author asserts that long distance navigation is one of the most fascinating aspects of animal behaviour, the book says very little about navigation (the term itself is never explained) and most of the work described is now out of date. For example, the chapter on bird migration and navigation discusses pigeon homing without mentioning any work more recent than about 1955, and the account of stellar orientation refers only to the early work of Sauer. One does not expect a popular book to be right up to date, but any such book should not be as outdated as this one.

John Krebs

Introduction to Liquid Crystals. Edited by E B. Priestley, Peter J Wojtowicz and Ping Sheng. Pp xi+356. (Plenum: New York and London, 1975.) $27.

THIS book derives from seminars given at RCA Laboratories in Princeton in 1973 and it is strongly polarised, theoretically and practically, towards the technology of using liquid crystals in electro-optical devices. The preface states this, but the book title is potentially misleading to those expecting an introduction to liquid crystals as a whole The book is also mainly concerned with the physics of the relevant liquid crystals (nematic, cholesteric, smectic A); the chemical input is small, and, disappointingly, no analysis of the relative chemical merits of available liquid crystal materials emerges. The book is, however, a valuable and timely text on the physics of liquid crystals in relation to their use in displays and one which will benefit all concerned with this technology.

Being multi-authored, the 18 chapters vary in quality; those on nematic order, continuum theory, electrohydrodynamic instabilities, Landau–de Gennes theory of phase transitions, and the packaging and addressing techniques for liquid crystal displays are very good. The end chapter on lyotropic liquid crystal systems and membranes points to a growing awareness of the possible technological scope for these types of system.

References to the 1974 literature are quite numerous. The presentation of the text, diagrams and equations is clear, and the index provided is adequate.

G. W. Gray

The Seismics of Heterogeneous and Turbid Media. By A. N. Nikolaev. Translated from Russian. Pp. iv+140. (Israel Program for Scientific Translations· Jerusalem; Wiley: Chichester, February 1976) £8.25; $16.50.

THIS is a study of the theory and observations of small-scale variations in the elastic parameters (the turbidity) of the Earth. Fundamental questions arising from the definition of "small-scale", and from the treatment of such variations as random, are unfortunately left largely unresolved; the underlying theory is based on the scalar wave equation and the reader is merely referred to the literature on the question of validity. Ultimately the author defines a "turbidity factor" which is to be integrated along a seismic ray to get the mean square variation in log amplitude—a formula quaintly described as "usually invalid" but "nevertheless . . . useful" Regrettably it is noted later on that its validity is not yet verified by experiment. Some model experiments, however, are described and the design of field experiments and analysis of certain observations are given in some detail. The net results are contained in plots of turbidity against depth for sections of one continental and three oceanic crusts, leaving the reader somewhat in the dark as to the related physical properties of the medium The book is very hard to read as the result of a rather ham-fisted translation

nature

July 15, 1976

Nuclear industry goes public

RECENT years have demonstrated that, in Britain at least, if any of the components of the unholy government–industry–trades union triumvirate start making signs that they are taking a view on a matter, that matter is fast becoming an important issue. So when the *Financial Times* organises a conference on nuclear power—or, more precisely, "Nuclear Power and the Public Interest: the Implication for Business"—it's a fair bet that energy, and specifically nuclear energy, is an item on the UK public agenda.

Evidence for this, of course, was around before last week's conference. Mr Benn, the UK Energy Minister, saw to that (if the world's energy problems hadn't already done so) with his recent energy talk-in and his public debate six months ago on the reprocessing of nuclear fuel. But with evidence a-plenty offered at the conference to show that the future use of nuclear power in industrialised countries could not be escaped, short of a return to an agragrian economy or a drastic fall in living standards, the nuclear issue seemed more confined than usual.

Still, the problem of the long lead-times attaching to nuclear operations helps to make nuclear power the live issue it now is. The likelihood of a UK "energy gap" in the 1990s is disputed in some quarters and subject to uncertainties, but if it is to appear, and sooner rather than later, it means decisions on nuclear programmes are needed now, with a correspondingly bigger margin of doubt on all fronts. And where there are decisions to be made, there too will the issues be created.

Hardly surprising, then, that people in the nuclear industry should be talking, a little over-dramatically, of its very survival over the period of energy surplus. Hardly surprising, either, that the Department of Energy, which doesn't yet doubt that the nuclear option must at least be retained, should become the object of attention for those seeking to influence the decisions which the "public" character of the nuclear issue now foreshadows.

The critical decision, on whether to go ahead with a demonstration fast breeder reactor (FBR), is expected sometime in the autumn. Unexpected, if heavily qualified, support for a demonstration FBR came at the conference from the Chairman of the Royal Commission on Environmental Pollution, Sir Brian Flowers (now looking at the effect of nuclear power), and from Leslie Grainger of the National Coal Board. Great uncertainty was again expressed, however, about the fate of the Steam Generating Heavy Water Reactor (SGHWR).

On less specific though no less important aspects of nuclear power, grave doubts were expressed, and brave responses offered: about the disposal of radioactive wastes after reprocessing (confidence was expressed about glassification techniques, and about burial in deep holes or under the ocean bed); about health and safety in the nuclear industry (favourable comparisons were drawn with other industries, and especially coal); about proliferation through international nuclear trade (to stop this, claimed one businessman, would be to encourage countries to develop their own technology over a longer period); about the chances of a nuclear accident (all necessary precautions were taken) and nuclear terrorism (the chances of a successful action were minimal); and about the economic facts of nuclear power (which, like all economic "facts", it became apparent, translate only as interpretations). To emerge with the right questions seemed more important in the end than having pat answers.

This was less true of other controversial questions which were broached about the nuclear issue. What should the role of the state be in the nuclear industry, if not in encouraging private enterprise in its task? How was a stream of steady orders to be secured to tide the UK industry over the coming years, if not by breaking into the export business with a marketable reactor? How was any progress to be made without international cooperation, specifically with Britain's European partners? Disappointingly, these questions, for most delegates, contained their own answers.

Not that the unique long term aspects of nuclear power ("making decisions for future generations") weren't acknowledged. But views on nuclear power for the most part revealed differences of detail rather than principle. Although the differences weren't insubstantial for that, there was unfortunately no real voice posing the obvious question—namely, who or what is the anti-nuclear lobby in Britain? (Everyone knows the answer to the analogous American question.)

This latest conference on the subject indicated that the British nuclear industry is finding it necessary to change its public position by actually adopting one. But if nuclear power is really on the public agenda, there are still more fundamental issues to be discussed, if only to be confirmed as resolved. □

The weather a week ahead

Ernest Knighting describes the establishment of the European Centre for Medium Range Weather Forecasts

RELIABLE weather forecasts for a week or so ahead would be of great economic value; almost every industry, including agriculture, transport, building, shipping, fuel and power, would benefit in the planning of operations and, of course, the general public would be better able to plan outdoor activities. And if, as has been estimated, the benefit to Europe would be more than £100 million a year at 1970 values, it is well worth setting up an organisation to conduct research into problems associated with medium range forecasting, and eventually to provide operational forecasts.

The resources of skilled manpower and equipment required for such a task, however, exceed those normally available at national level. This makes an international co-operative effort necessary, and in October 1973 sixteen European nations signed a Convention establishing the European Centre for Medium Range Weather Forecasts. By November of last year a sufficient number of nations had ratified the Convention for the Centre to come into being. Belgium, Denmark, West Germany, Spain, France, Ireland, Yugoslavia, the Netherlands, Austria, Portugal, Switzerland, Finland, Sweden, Turkey and the UK have ratified, while both Greece and Italy are expected to ratify shortly.

The Centre's headquarters (to be erected by the UK Government) will be at Shinfield Park, Reading, England; temporary accommodation has meanwhile been provided at Bracknell. The Centre will have a staff of about 140, including about 70 graduates, mostly in the research and operations department. The present staff, numbering about 40, reflects the international character of the Centre, with nine member nations being represented. In addition there will be opportunities for visiting scientists to work at the Centre.

The Director, the well-known Danish meteorologist, Professor Aksel Wiin-Nielsen, was formerly Head of the Department of Atmospheric and Oceanic Sciences at the University of Michigan; he, together with a small planning staff, laid the foundations of the Centre's development so that at its official birth it was already well-advanced in its scientific and operational planning. When the Centre is fully operational it is expected to have a yearly budget of about £6 million; the cost will be met by the member nations, contributions being scaled according to the gross national product of each nation.

The central premise of the development of these operational forecasts is that the atmosphere may be regarded as a compressible fluid, its behaviour being described by the Navier–Stokes equation and the thermodynamic equations concerned with sources, sinks and the transfers of energy. Considerable progress has been made in the last two decades in using these equations for two distinct objectives. The first is for short-range weather forecasts for a day or two ahead, and it is now common for national services, especially those in extra-tropical latitudes, to base their short-range forecasts on the numerical integration of the equations. The problem is the prediction with considerable accuracy of the motion and development of weather-bearing systems, which have a lifetime of a week or so; it requires a fairly precise knowledge of the state of the atmosphere at the instant from which the forecast proceeds, while some slow acting physical processes may be neglected.

The second objective is to determine why the atmosphere has its general climatic structure and to throw light on climatic change. In this research the equations are integrated for perhaps a hundred days or more rather than for the one or two days of the short-range forecast. During this period many generations of weather-bearing systems undergo their life history and the emphasis is no longer on the initial detail but on the careful representation of the physical processes that are thought to be important for the atmospheric development over a long time, such as incoming and outgoing radiation, the transfer of energy at the earth's surface and so on.

Forecasting for up to ten days ahead presents a more difficult problem because both the initial details and the careful accounting for the physics have to be taken into consideration. The detail must be considered because the evolution of the atmospheric systems in existence initially has a considerable effect over the period; indeed, some of the systems may persist, although modified in form and position, for most or the whole of it. The changes caused by the slow acting physical processes can also be profound during the period; the effect of a change in sea surface temperature, for example, due perhaps to up-welling, can be remarkable. Over a few days the development of the weather bearing systems over Europe and the Atlantic can be affected by what is happening very far away, and forecasts for ten days ahead need to be global, taking into account the developments in the Southern Hemisphere, which are less well defined, as well as in the Northern Hemisphere.

Professor Wiin-Nielsen, ECMRWF Director

The equations describing the evolution of atmospheric motions are highly non-linear and whether any useful analytic solutions will ever be obtained seems doubtful. Certainly the only known methods of solution are numerical, and the arithmetic burden is enormous: operational numerical forecasts for a couple of days ahead require the use of large-scale computing facilities with speeds of operation of about 10 million instructions per second; computations associated with operational forecasting up to ten days ahead call for facilities about five times as fast.

If the Centre is to achieve the difficult, perhaps impossible, target it has set itself—namely to be in a position to provide daily operational forecasts before the end of 1980—there must be scientific research and development on three fronts. The first concerns the acquisition of the right daily data, its verification and reduction to a suitable form. This problem has become very complicated because a great number of meteorological data, especially those from satellites, are observed continuously and require special methods of assimilation if they are to be used in the forecasting process. The second concerns the important physical processes which often cannot be represented directly in the computations because the arithmetic has to be carried out for discrete grid points about 100 km apart. Atmospheric processes smaller in size than this can only be represented statistically in the computations. Many of the important energy transfers—those due to vertical instability and the development of cumulonimbus clouds, for example—are subgrid scale in size and their important contribution to the working of the atmosphere needs investigating. The third concerns the selection of the mathematical methods of integration, where there will be a delicate balance between accuracy and economy.

An additional complication is the problem of predictability which is currently exercising meteorologists. It is the problem of determining for how long ahead useful forecasts can be made. It is generally agreed that the limit is less than one month and more than five or six days, using current mathematical models and the meteorological observations presently available. Experimental determination of the limit by integration of the model equation is very difficult because a few integrations cannot give results representative of so variable a fluid as the atmosphere, while each integration predicting for, say, 14–20 days, is extremely costly. Experiments carried out up to date show that there is value in the forecasts up to ten days and this is confirmed by the few integrations carried out at the Centre. The Centre will cooperate as fully as it can in the First GARP Global Experiment, which is designed, among other objectives, to determine the limit of predictability.

With the aid of computer programmes for atmospheric models provided by the Geophysical Fluid Dynamics Laboratory of Princeton, the Department of Meteorology, UCLA, and the UK Meteorological Office, this research has already started. Ten days forecasts have already been made with these models, using both a CDC 6600 computer installed for the Centre's use by CDL in Bracknell and the UK Meteorological Office computer complex; their production is regarded as a familiarisation exercise.

A considerable effort must also be devoted to the selection and installation of suitable computing facilities; speeds of 50 million instructions per second are only just being developed and the selection of an integrated system capable of carrying out the data processing and the number-crunching on an operational basis will certainly present difficulties. Of course, the system must be available before 1980 since the Centre will need to develop its operational programmes on it.

Europe, through the member nations, has created the first scientific centre for the study and preparation of medium range weather forecasts. The international meteorological community has expressed great interest in this new venture with offers of help and cooperation. Already a cooperative agreement has been signed with the World Meteorological Organisation and the provision of computer programmes is one example of the help that has been made available. Nevertheless the Director and his staff face a difficult task in attempting to build up a new international scientific centre in a time of recession. □

USA

Science vs. the public

Colin Norman reports from Cambridge, Massachusetts, where attempts are being made to restrict recombinant DNA research.

In a move which establishes a virtually unprecedented degree of community control over an area of scientific research, the city council of Cambridge, Massachusetts, last week passed a resolution calling for a three-month moratorium on certain types of recombinant DNA research at Harvard and Massachusetts Institute of Technology. Though the moratorium will have little immediate impact, since experiments of the types outlawed by the council are not yet being conducted at either university, the council's actions could have broad and lasting implications.

While the moratorium is in effect, a special review board, also established by the council last week, will draw up recommendations to control recombinant DNA research in Cambridge. In addition the board has been given the astonishing task of reviewing all laboratory experiments in the city, to ensure that none of them poses a threat to public health.

The council's actions are the result of a bitter clash between groups of scientists, city officials and Cambridge residents over plans to conduct recombinant DNA research at Harvard and MIT. The dispute, which centres on the question of whether or not such experiments can be carried out safely, has been a bloody battle which has provided ample evidence of public distrust of scientists and which has further damaged the already abysmal relationships between the city and its two famous universities.

In a sense, the clash has also provided the first real test of public acceptability of federal safety guidelines governing recombinant DNA research issued last month by the National Institutes of Health (NIH) (see *Nature*, July 1). The guidelines were developed mostly by scientists, and have not previously been subjected to the intense public scrutiny now being lavished on them in Cambridge. Those who support the guidelines—and they include the vast majority of the scientific community—can take little comfort from the public debate in Cambridge. Moreover, many scientists are worried that similar clashes could break out elsewhere, a development which the Mayor of Cambridge has been doing his best to promote by trying to interest his fellow mayors in the issue.

The hostilities stem originally from a proposal, put forward two years ago by a group of scientists headed by Mark Ptashne, to convert some rooms on the fourth floor of the Harvard Biological Laboratories into a special safety facility. Designed primarily for experiments with the animal virus SV40—experiments which are frequently carried out in other institutions under much less stringent safety conditions—the facility became a major focus of controversy when the plans were modified to include space for some recombinant DNA work.

At present, Harvard researchers are restricted to experiments, judged by those who wrote the guidelines to entail little risk, which do not require special safety facilities. According to Matthew Meselson, Chairman of the Department of Biochemistry and Molecular Biology, about 30 people at Harvard are now working, at various levels, on such experiments. Construction of the safety laboratory—a moderate containment, or P3, facility under the NIH guidelines—would allow many other types of experiments to be undertaken at Harvard.

Opposition to the facility came first from scientists at Harvard. It took two forms. Some argued that although recombinant DNA research is an exciting and potentially revolutionary area of research which should be conducted at a major research institute like Harvard, the building housing the biological laboratories is unsuitable for a safety facility. It is old, infested with ants and cockroaches, and situated in a densely populated area. The second, more fundamental objection came from scientists who argued that recombinant DNA research is inherently so risky that virtually all such experiments should be confined initially to one or two specially equipped national facilities, or be outlawed entirely, until the hazards are better defined.

In spite of the intensity of the opposition construction of the facility has been approved in principle by a special biohazards committee, by Harvard's top-level committee on research policy, and by the Dean of Arts and Sciences. Final plans for the lab are now being drafted.

The internal dispute at the university spilled over into the city and mushroomed into a major political issue early last month when the matter was reported at length in the *Boston Phoenix*, a weekly area newspaper. At that point, Cambridge city Mayor Alfred E. Vellucci stepped in. An irascible, colourful, shrewd politician with 26 years' service on the council, Vellucci is no friend of Harvard or MIT. In fact, the strained relationships between town and gown in the city provide an important backdrop to the clash over recombinant DNA research in the city.

A major source of irritation is the fact that the two large, wealthy universities are situated in a predominantly industrial community and are exempt from paying many city taxes. There have also been problems over pressure on city housing—"If it gets any worse", Vellucci said in an interview last week, "we'll have to knock down some buildings for somewhere for people to live". A good example of town-gown friction came a few years ago when the city council passed a resolution, introduced by Vellucci, to pave over Harvard Yard and turn it into a parking lot. (The resolution, according to Vellucci, successfully spurred the universities into building more student parking facilities.)

Vellucci's dignity was pricked when he read in the *Phoenix* that Harvard scientists were planning to conduct reportedly dangerous experiments without first consulting city officials. And his belief in the dangers of the experiments was heightened by a visit from George Wald, a Nobel prizewinner and a vigorous opponent of the plans for the laboratory. Vellucci called a council meeting for June 23—ironically the day on which NIH issued its guidelines—to discuss the matter. The meeting provided a forum for a bitter clash between mostly radical scientists and their more establishment colleagues, with council members often bewildered and Mayor Vellucci enjoying the publicity, and especially enjoying the opportunity to haul Harvard intellectuals over the coals.

At one point in the proceedings, Vellucci particularly chastised Daniel Branton, chairman of the biohazards committee, for making little attempt to bring city officials into the discussions of plans for the safety laboratory. Branton protested that he had, but Vellucci scored a major debating point.

During the meeting, Vellucci proposed a resolution calling for a two-year moratorium on *all* recombinant DNA research in the city—even those experiments already under way which are judged to entail little risk. No vote was taken at that meeting, however, and it was adjourned after some five hours of bitter exchanges.

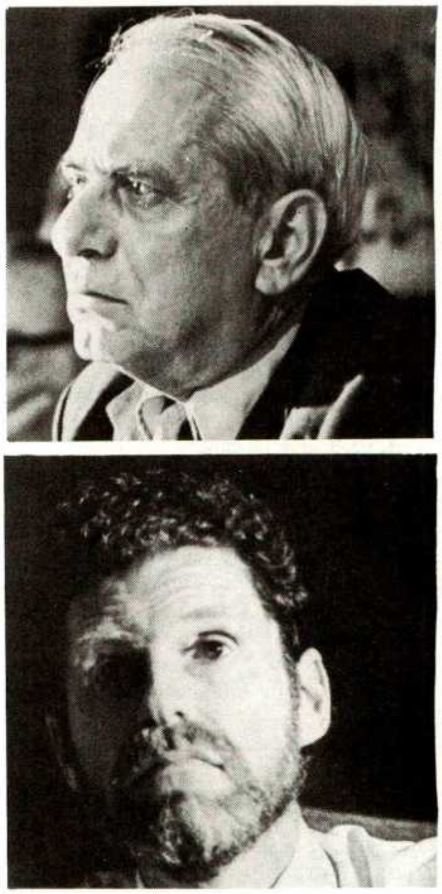
The next day, Vellucci issued a public statement declaring that the meeting "has made it clear to me that a 'cooling off' period is necessary in order for the mayor and the council to deal with this matter in a calm and rational way". He then softened his proposal for a two-year moratorium, calling instead for a three-month 'good faith' halt to the research "so that all concerned can properly review relevant testimony. He later offered another proposal to establish a review board to look into the issue and to examine other research programs at Harvard and MIT to see whether any pose a potential public health risk. A second council meeting was called on July 7 to resume testimony and to discuss the resolutions.

In the fortnight between the meetings, some councillors and the mayor spent a good deal of time contacting, and being contacted by, scientists. As a result, Vellucci announced to the meeting last week that he had "learned enough about recombinant DNA molecules in the last two weeks to take on all the Nobel prizewinners in the city of Cambridge". He has certainly taken on most of them.

The meeting began with a demonstration of techniques used in microbiology, for the councillors' edification. Meselson then described the formulation of the NIH guidelines, noting that in each new draft they were made more strict. And William Gartland, Director of the newly created NIH Recombinant DNA Activity Unit, described the guidelines themselves, pointing out in particular the contrast with the situation in the United Kingdom, where the whole business of setting regulations on the research is taking place behind closed doors.

At that stage, Councillor David Clem, a young, articulate council member who has obviously done his homework on the issue, proposed a number of amendments to Vellucci's resoultions. The most important change was an amendment to limit the moratorium to research requiring P3 and P4 facilities, according to the NIH guidelines. That amendment was accepted without debate, even though it meant the difference between stopping several experiments and stopping nothing.

Harvard has no P3 or P4 facility, so no such experiments are going on there. MIT, however, has a P3 facility in the Center for Cancer Research, but no P3 level experiments have yet been initiated. One experiment is being planned at the facility by Dr Philip Sharp, however. He said last week that he has been holding off on the research—which would involve inserting mammalian genes into *E. coli*—until the NIH guidelines had been published, and that it would take at least three months to get the experiment approved and under way.



Mayor Alfred Vellucci (top) and (below) Daniel Branton

Another council member, Sandra Graham, then proposed that the moratorium should be extended from three months to six. After some debate, the amendment was defeated by six votes to two. Vellucci then proposed that the moratorium should be extended to two years if no agreement has been reached at the end of three months. That was also defeated by six votes to two. At that point, the resolution with Clem's amendment was approved by five votes to four.

The second resolution, establishing a Cambridge Laboratory Experimentation Review Board, was then voted on, and similarly approved by five votes to four.

With the amended resolutions approved further testimony on them became superfluous but it was taken anyway—until 12.45 am—with the council chamber packed with scientists and with people from both sides heatedly stating their views.

A number of interviews with scientists the day after the meeting demonstrated that both sides are relatively pleased with the outcome so far. Proponents of the research are happy that the moratorium will do no damage to current research and that it is much less restrictive than the original resolutions. And opponents of the research are pleased that the vote has established the principle of community control over scientific research.

There is, however, considerable unease within the scientific community, and with good reason. The council meeting secured a precarious ceasefire, which could easily erupt into renewed hostilities. An important factor in what happens next will be the work of the experimentation review board. Its terms of reference are broad and hazy, and its members are yet to be appointed. One potential member is George Wald, who was asked by Vellucci last week whether he would serve if asked and replied that he would be "happy and honoured to do so". Vellucci said after the meeting that the board would contain both supporters and opponents of the research and that some city residents would also be included. If necessary, he said, he would lock them all into a room and not let them out until they have come to an agreement.

Creation of the board has at least taken the council out of its uncomfortable position in the middle of the dispute. But if the board has not reached agreement at the end of three months, the council will be thrown right back in and there would then be a possibility that the moratorium would be lengthened and, perhaps, broadened. Alternatively, if the board vigorously pursues its mandate to look into all laboratory work in Cambridge, there is a danger that it could turn into a public witch hunt. "We will be keeping our fingers crossed in the next three months," says Richard Leahy, a dean in the Faculty of Arts and Sciences.

On the other hand, creation of the review board at least establishes a long-needed channel of communication between the university scientists and the city. It could provide an important vehicle for informing and educating the people of Cambridge about recombinant DNA research and about the process which led to adoption of the NIH guidelines. It is conceivable that it could even help smooth some of the causes of town–gown friction.

Another possibility which is clearly worrying people far removed from Cambridge is that similar clashes could erupt in other cities. In that respect, Vellucci has been active. Last month he attended a meeting of the United States Conference of Mayors armed with a resolution stating that "no university or institution may begin recombinant DNA experiments without first notifying the mayor of the city or town in which the experimentation will take place. Thereupon, the mayor and legislative body shall call a public hearing so that the public may be an active participant in the decision-making process". The resolution was referred to a committee for consideration, and Vellucci said last week that he intends to press the matter at future meetings.

It is possible that the dispute in Cambridge will now quietly die away. But with so many articulate and politically motivated scientists opposed to the research there, the prospects at this stage are far from certain. The next few months will be critical. ☐

EEC

JRC programme awaits approval

The Commission of the EEC has circulated final proposals for the next multiannual research programme of the Joint Research Centre. These now await ratification from the Council of Ministers. Chris Sherwell reports

THE multiannual research programme of the European Community's Joint Research Centre (JRC) for the four years beginning in January 1977, the final detailed proposals for which were submitted by the Commission to the Council of Ministers some two weeks ahead of the Council's May 24 meeting, may not be approved before September, even though preliminary discussions of the overall framework for the Community's 1977 budget are due to start later this month.

The Council decided at the May meeting to consult both the European Parliament and the Economic and Social Committee, even though there is a clear need for the JRC's budgetary requirements for 1977 to be entered into the budget for the coming financial year. The European Parliament is being urged to deliver its opinion no later than its part-session in September, which is about the time when the Finance Ministers are expected to be reaching more concrete budgetary decisions.

The Commission's proposed programme represents the outcome of many months of behind-the-scenes deliberation, including broad consultation with research and administrative staff. Last October the Commission sent to the Council its "Overall Concept" for the programme, setting out guidelines for the JRC's future role, and this the Council discussed at an inconclusive December meeting along with a document on a joint research and development policy. Other discussions took place in February, and the General Advisory Committee considered the draft programme in March and the Scientific and Technical Committee considered it in April.

The Commission has already stated that in framing the new programme it took into account "criticism made in the European Parliament and elsewhere" that the JRC "had engaged in too many 'half-baked' projects which it had not the resources to complete"—criticism which arose, it said, "in part from the failure of the member states to provide the Centre with effective guidelines".

Details of the final proposals now under consideration are shown in the accompanying table, but do not include the installation of the JET fusion project, which the Commission wants at Ispra, since a decision on the matter is still awaited.

In its final proposals the Commission points out, some would say rather obviously, that among the guiding principles of the programme, primary consideration was given to the Community's interests in science and technology. From its discussion of these principles and of the JRC's role, however, a few important points emerge, namely, the priority being accorded to energy and environment questions, the stress on a Community public service role for the JRC (that is, making equipment, know-how, products and services available), and the concentration of activities and research potential on a small number of projects. There is also emphasis on the "rolling plan" character of the proposed programme, and on management and staff aspects.

The three-year rolling system, proposed in order to allow a greater degree of adaptability, is quite simple. The four-year programme would be submitted during the third year, when the Council would adopt a new four-year programme in which the last year of the initial programme would become the first year of the new programme. The new programme would itself be submitted for revision during its third year, when a decision would be taken on the following programme. In the absence of decisions, current programmes would be continued according to the Council's original decisions.

Regarding the financial requirement over the forthcoming four-year period of 374.4 million units of account (£156 million), the Commission says the pattern of investment expenditure envisaged means in practice that it will not be divided into equal annual parts; rather, it is expected that the annual budgets will actually show a decrease over the four years.

The impact of proposals regarding researchers attached to the JRC has statistical consequences to which the Commission draws attention. Its concern over their mobility is reflected in the proposal, approved broadly by the European Parliament and still under examination by the Council (the Commission urges that it be adopted as soon as possible), for a different manner of payment; a new "research staff" concept is also adopted which stretches beyond existing "first line staff" to include associated technical support staff.

Thus, as the document goes on to point out, if the "research staff" number and programme expenditure are taken together as a measure of the distribution of effort within the JRC, programmes I, II and III (which can be broadly classed as "nuclear safety") take up 48% of the total, future

The Multiannual Research Programme of the JRC proposed by the European Commission

	Programme	Projects in programme	Personnel			Specific Programme Expenditures (muc)	Staff Costs research[2] (muc)	Global Supporting Costs (muc)	Total Costs (muc)
			Total	Research Staff	Others[1]				
I	Reactor Safety	Reliability and risk assessment; Light water reactors loss of coolant accidents; Liquid metal fast breeder subassembly thermohydraulics; Fuel coolant interactions and core melt-down; Dynamic structure loading and response; Structural failure prevention	440	239	201	16.52	38.38	37.23	92.13
II	Plutonium fuels and actinide research	Utilisation limits on plutonium fuels; Plutonium and actinide aspects of the safety of the nuclear fuel cycle; Actinide research	209	121	88	6.6	15.3	19.58	41.48
III	Management of nuclear materials and radioactive waste	Evaluation of long term hazards of radioactive waste disposal; Chemical separation and nuclear transmutation of actinides; Fuel materials management; Reactor component decontamination studies	161	97	64	4.36	15.78	14.24	34.38
IV	Solar energy	Thermal conversion in housing; construction of European installation to simulate solar irradiation; orientative research on advanced applications of solar energy	57	35	22	4.86	5.67	6.74	17.27
V	Hydrogen	Thermochemical processes for water decomposition; heat source coupling	78	50	28	2.4	8.14	5.92	16.46
VI	Conceptual studies on thermonuclear fusion	Participation in conceptual study of an experimental power reactor in connection with Euratom-CNEN association at Frascati (blanket neutronics, heat transfer and energy conversion systems etc)	14	8	6	0.28	1.28	0.99	2.55
VII	High temperature materials	Industrial needs; effect of operational environment on mechanical properties; failure modes in applications; relationship of structure and properties	51	36	15	2.21	4.44	2.54	9.19
VIII	Environment and resources	Atmosphere; water; chemicals, renewable (agricultural) resources	188	115	73	5.01	18.73	17.59	41.33
IX	Measurements, standards and reference techniques	Measurement of nuclear data; nuclear and non-nuclear reference methods and techniques; scientific support to the services of the Commission and Secretariat of Community Bureau of Reference	286	181	105	8.185	25.51	25.995	59.69
X	Services and support activities	Exploitation of high flux reactor; informatics; education and training; safeguards; technical evaluations in support to the Commission	221	116	105	26.505	14.94	18.465	59.91
	Totals		1,705[3]	998	707	76.93	148.17	149.29	374.39

Units of account based on value at 1 January 1977

[1] Does not include 471 local agents not presently classed as personnel because they are paid from funds allocated yearly from the appropriate section of the budget

[2] Includes laboratory equipment costs

[3] To this total must be added 183 people relating to the ESSOR reactor.

energies (programmes IV, V, VI and VII) take up 12%, environment and resources 10%, reference work 17% and support 13%

This as the Commission says, means that effectively 70% of the JRC's effort will be devoted to "energy and the environment", with much of the effort in energy concerned with nuclear safety. The Commission points out elsewhere that the proposals also achieve a better (60 · 40) balance in the ratio of payroll costs (214.6 muc) to operating expenses (159.8 muc).

The new programme, provided it is adopted in time, will follow on the existing multiannual programme, adopted in 1973, being carried out in the four JRC establishments at Geel (Belgium), Ispra (Italy), Karlsruhe (West Germany), and Petten (Holland) The large body of the work will be at Ispra. Karlsruhe will take the lead in plutonium fuels and actinide research, Petten will work on high temperature materials, and Geel will coordinate the work on reference methods. ☐

BRAZIL

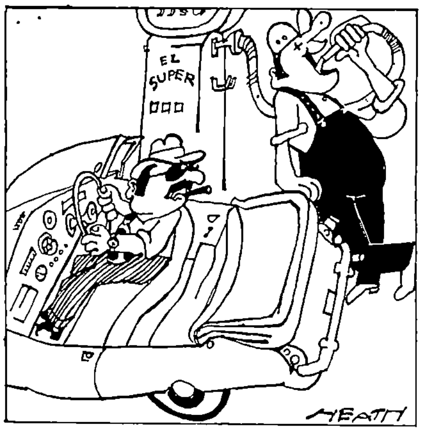
● Brazilian engineers have now succeeded in modifying an automobile engine to run on pure alcohol. This could be significant in solving energy problems here, in view of the fact that Brazil imports more than 80% of the crude oil it uses for making petrol. The experimental engine, installed in a Brazilian-made Dodge sedan and demonstrated to government officials in Brasilia, achieved 23 miles per gallon—roughly the same as that model gets with a gasoline engine—and had no trouble keeping up a steady 55 miles per hour in a highway test. The alcohol engine also released far fewer pollutants in its exhaust than a standard engine. Brazil's commerce and industry minister, Severo Gomes, was impressed by the demonstration. He said that if an alcohol engine is produced in volume here, it will be put first in buses and taxis in big cities.

Brazil has the potential to be self-sufficient in alcohol fuel. It is the world's biggest cane sugar grower (sugar is the country's current prime source of alcohol), and it has unmeasured quantities of cassava, a plant whose root provides a basic food for millions of poor farmers and which local scientists say can also be made to yield commercially usable alcohol.

The government's oil refining monopoly, Petrobras, currently dilutes its gasoline by 20% with alcohol, to make imported crude oil stretch further.

● Sao Paulo, Brazil's biggest metropolis (city population: 7 million; including the suburbs: 10 million), also has South America's biggest air pollution problem A combination of thermal inversion, industrial smoke and automobile exhaust gives Sao Paulo the look of London in the days before anti-pollution measures went into effect in Britain. The air quality in Sao Paulo is often so bad that department stores take out newspaper advertisements for filter masks.

But now local health officials have persuaded the mayor's office and the police to cooperate in a plan called "Operation Winter", which will be put into effect on badly polluted days during the South American winter (June–September), when pollution-trapping temperature inversion is at its worst in Sao Paulo. The operation has three stages· a warning level, an alert level, and an emergency level when local authorities will prohibit the use of petrol and diesel-powered vehicles, shut down all factories and prohibit all burning.



This type of action has never before been contemplated in Brazil, where the official line has been that pollution is the price a developing country must pay if it wishes to progress since time spent on its control is time wasted.

● Brazil has been complimented for its progressive laws protecting wildlife and, at the same time, criticised for its inability to enforce them. This is especially true in the vast, underpopulated Amazon region, where it is virtually impossible to control illegal trafficking of protected species of birds and animals.

Occasionally, though, the authorities get results. Police in Rio followed up a recent tip that dogs and cats in a residential neighbourhood had been mysteriously disappearing, and this led them to what apparently is a large-scale contraband ring for exporting Brazilian Amazon creatures such as monkeys, parrots, parakeets, tucans and canaries.

Four persons were arrested on suspicion of running an illegal animal trade to Europe, North America and Japan. The police found hundreds of caged birds and monkeys awaiting shipment out of the country. They also found many dead animals which did not survive flights from the Amazon city of Belem to Rio. The operators of the smuggling ring apparently had been using local dogs and cats to make food for the captured Amazon animals.

In similar actions, police in Sao Paulo and Fortaleza recently broke up illegal trafficking in songbirds which are protected by wildlife laws. There is a big local demand for many varieties of these popular birds in Brazil, and breeders and sellers seem willing to run the risks to make a profit.

● In another instance of Brazil's finally applying a law that had seemingly existed only on paper before, naval authorities in the north-eastern city of Salvador slapped a fine equivalent to $25,000 on a local titanium company after a pipe broke at its factory and sent sulphuric acid and ferrous sulphate spilling on to Atlantic Ocean beaches, leaving a brownish stain several miles long in the water. Among the beaches hit was Arembepe, which often is played up in tourist brochures as a Brazilian "unpolluted paradise".

● Brazil's biggest lagoon, Lagoa dos Patos, which is near the country's far southern tip, is becoming so polluted that fish and shrimp are dying *en masse*, and even some farm animals have died of poisoning after drinking water from it Scientists at the Rio Grande do Sul State Center for Toxicological Studies are not sure, but they think the cause is a sharp increase in the use of DDT and other insecticides on nearby farms Soybean and wheat production in Rio Grande do Sul have gone up dramatically in recent years, and farmers there traditionally have used large amounts of pesticides.

Fishermen around Lagoa dos Patos say their annual catch in the 3,800-square-mile lagoon is going down steadily. And bird watchers in the region have noticed that the once-common marsh cardinal no longer is seen and that the Patagonian duck does not stop at the lagoon any more on its winter flight north from Argentina.

Bruce Handler
Rio de Janeiro

SWEDEN

Nuclear fuel report out

After three and a half years of study, the Swedish Commission on Spent Nuclear Fuel and Radioactive Waste recently produced its final report. Wendy Barnaby sent this view from Stockholm.

"Even today's techniques offer satisfactory possibilities for the handling and storage of spent nuclear fuel and radioactive waste." Such is the assessment of the Swedish Commission on Spent Nuclear Fuel and Radioactive Waste, whose task was to study the management of low-, medium- and high-level radioactive wastes—that is, not only those from nuclear power plants, but also those from research institutions, hospitals and industry.

The timing of the report was no doubt planned to support the government's pro-nuclear power stance in the current general election campaign, in which the ruling Social Democrats are under heavy pressure from the opposition—part of which is adamantly opposed to nuclear power. Thus the report's claim—that its "central demand" was that all steps in the handling of radioactive waste had to be formulated with regard to the protection of people and their environment now and in the future—sounds suspiciously like an attempt to pull the carpet out from underneath the opposition, whose criticism of the safety and environmental aspects of nuclear power has mobilised an unusually large following. The latest opinion polls show that both government and opposition parties have lost support for their nuclear energy platforms since last January and that, while the opposition's policy is still more popular than the government's, more people are doubting the wisdom of either. This result will obviously stimulate each camp to even greater propaganda efforts than before, and the Commission's report will undoubtedly be one of the government's main weapons.

The report has not definitely pronounced on the fate of Sweden's spent fuel. "We recommend that this decision should be taken in 1981 or 1982", says the Commission's Secretary, Mr Philip Moding. The options are to continue sending spent fuel abroad for reprocessing, or to deal with it in Sweden reprocessed or not. In the long term, sending it abroad is no satisfactory solution. Under an agreement that will last until 1980, spent fuel from the Oskarshamn plant is being sent for reprocessing to Windscale in England. Negotiations are presently going on between the Swedish Nuclear Fuel Supply Company (SKBF) and United Reprocessors, jointly owned by British, French and German interests, for the spent fuel that will be taken from plants already in operation at Ringhals, Forsmark and Barsebäck. A preliminary understanding has been reached but nothing has been signed, and the hoped-for agreement would probably only last until 1980 anyway. "It will be necessary for us to build an intermediate storage capacity for spent fuel in any case", says the Director of SKBF and an expert adviser to the Commission, Dr Erik Svenke, "because even if we continue to send spent fuel abroad, the reprocessor will have the right to return the waste to Sweden and we would then have to store it here."

The report urges the acceleration of research into ways of handling spent fuel domestically without reprocessing. How seriously this proposition is meant is hard to say. A domestic solution will in the long term certainly be preferred to the difficulties and uncertainties of sending it abroad, especially as Sweden's neutrality makes the country seek as much independence as possible in questions related to its national security; and it seems almost certain that a reprocessing plant, with its attendant business opportunities and relative simplification of storage of remaining waste, will then seem the best solution. Dr Svenke is convinced that Sweden will have to build a reprocessing plant at some time. "A country with a civil nuclear programme has a responsibility to take care of its waste", he says

According to the report, any decision to build such a plant should go hand in hand with one to construct a fuel fabrication plant, to ensure that both plutonium and uranium are re-used as fuel. It estimates that a reprocessing plant with a capacity of 800 tons of uranium a year (and offering employment for 1,000 people) would take about 13 years to build. The Social Democrats' plans for Sweden's nuclear future envisage 13 reactors in operation by 1985 So far, five are running and five others are under construction. When all are operating, the country's total net nuclear power capacity will be about 10 GWe and, it is estimated, the reactors will produce about 300 tons of spent fuel a year. The reprocessing plant's excess capacity would be intended for other countries' waste. The Nordic countries would be obvious participants, although neither Denmark nor Norway has yet decided to build nuclear power plants. Finland, however, had three under construction at the beginning of this year, and it is expected that they will produce about 2.2 GWe by 1985.

The method of disposal recommended by the Commission is to melt the highly radioactive waste in glass and deposit the medium- and low-level waste in concrete, then store it all in vertical tunnels drilled out of bedrock at a depth of 300–400 metres. Studies made by the Geological Survey of Sweden have pronounced bedrock conditions stable and suitable for such storage. "It is very important that the Commission has demonstrated that the terminal storage problem can be solved in Swedish bedrock", says Dr Svenke. "It signifies that the fuel cycle can in fact be closed."

The President of Sweden's Friends of the Earth group, Lennart Daléus, however, is not so optimistic. "What the Commission is telling us", he maintains, "is that with current techniques and those they hope will be developed in the future, the problems of high-level radioactive waste disposal can be solved. But in fact this is more a hope than a technical certainty." He also raises broader issues which he says the report should have considered. What are the social and moral implications of undertaking to secure radioactivity for hundreds of years? How can we possibly be sure that future political regimes will be willing or able to take care of our waste? Dr Svenke does not think these issues are relevant. "The terminal storage of radioactive waste", he says, "is surely a technical problem. It does not have the same dimensions as other aspects of the question: the relationship between the spread of nuclear energy and the proliferation of nuclear weapons, for example"—although he is apparently prepared to take the risk of proliferation.

The report gives only a brief mention to the problems of terrorism and theft of plutonium, and it is noteworthy that one of the parliamentary members of the Commission, John Takman, felt obliged to publish an addendum to the report expressing his regret that the Commission had not taken more account of the relationship between nuclear energy and nuclear weapons. If the more pessimistic experts are proved right, and the spread of civil nuclear energy programmes does result in nuclear-weapon proliferation which does in turn produce global nuclear catastrophe, all the present arguments will be shown to be ironically irrelevant.

Such predictions, however, are not the stuff electoral victories are made of Sweden's nuclear future will have to wait for clarification until September, when the results are known. ☐

ISRAEL

● Some unfashionable opinions on science and defence were expressed in Israel by Sir John Kendrew, now Director-General of the European Molecular Biology Laboratory in Heidelberg, when he spoke at a symposium marking the 60th birthday of Israel's scientist-President, Professor Ephraim Katzir. Sir John pointed out that Israeli scientists, living in a nation which had fought several wars of national survival, faced little moral conflict when it came to doing defence research. British scientists, in contrast, found such research "boring and disreputable."

"We now tacitly assume, in my opinion contrary to the evidence, that defence research is no longer necessary, that the Western countries will probably never again be at war Our younger scientists don't want to get involved, and as a result our defence committees are manned by greybeards". Given the imperfections of the world we live in, Kendrew added, "I think that defence research is necessary still, even though it might not be as obvious as it was during the Second World War when I was masquerading as an Air Force officer and Crick as a Naval officer".

Kendrew expressed scepticism as to whether international agreements for arms control could be enforced, a scepticism which was not shared by Professor Carl Goran Heden of Stockholm's Karolinska Institute, who also participated in the symposium. As he stated in his multi-volume report on biological warfare that was prepared for the Stockholm International Peace Institute (SIPRI), Heden thinks that the major powers will make and keep agreements. He admits, however, that small groups of fanatics might take the law into their own hands, which emphasises the need for an international criminal code to deal with such groups.

● If Israeli lives are to be saved, military research may be less important than research on traffic accidents, which claim far more victims than do the fields of battle Israeli motorists kill off one another, as well as pedestrians, at a rate practically unequalled elsewhere In 1970, the last year for which figures are available, the accident rate per million kilometres travelled was 0 7 in the US, 1 3 in the UK and France and 2 3 in Israel. Only the drivers of Japan and Belgium were more lethal

In an attempt to cut down on the carnage, the Israeli police have decided to adopt a plan proposed by plasma physicist turned traffic expert Gerry Ben-David, who aims at re-educating the entire population of Israeli drivers. It is based on putting drivers under close observation and swiftly making them aware of their mistakes. First tried out on a very limited basis, it will now encompass 10% of Israeli highways.

Placed at strategic points along these roads will be specially trained teams, each member of which will concentrate on certain traffic violations. Every violation will be recorded, as will the licence number of the car concerned (though no attempt will be made to stop the vehicle). The violation data will be transferred for computer processing using standard techniques, and the computer programme will be then control all subsequent communication with the driver. Computerisation makes it possible to ensure that within a matter of days the person (or company) in whose name the car is registered will receive a letter from the traffic police giving full details of the offence and pointing out the dangers involved in such behaviour If the owner himself was not driving his vehicle at the time, he will be asked to identify the actual driver so that he can be contacted

During the initial, small-scale trial of the Ben-David scheme, observers witnessed an extraordinary number of traffic violations. One four-man team, for example, reported 6,086 offences in one month along just one section of the road, the most common violations being close driving, unnecessary driving in the lane reserved for passing, and speeding. Motorists "caught" up to three times were sent letters, while those guilty of more traffic violations were asked to come for a talk with the police or perhaps even forced to undergo a new driving test before being allowed to continue on the road.

While Dr Ben-David cannot yet prove that his scheme actually prevents traffic accidents, he notes that a follow-up carried out during the preliminary trial of his system showed that the observed violation rate dropped more than 50% for drivers who received a single letter and 80% for those who received three letters. When observation teams are operating over large stretches of Israeli highways, he feels certain that there will be a significant drop in the countrywide accident rate

Accident prevention in Israel involves special problems, notably the fact that 75% of the drivers have been on the road for less than 10 years. At the same time, drunkenness, a major cause of accidents in other Western countries, is practically unknown. In spite of the differences, if Dr Ben-David's system works in Israel it may also work elsewhere.

● After a hard day of driving, exhausted Israelis slump into their armchairs and turn on the TV, anxious for entertainment rather than education. It may be for this reason that Israeli TV allocates so little time for science, particularly locally produced programmes.

This month, however, viewers were introduced to an excellent new TV series on archaeology which gives them both science and entertainment, the latter stemming from the fact that the man who explains the archaeology is a master entertainer. Hebrew University Professor Yigael Yadin is no ordinary archaeologist: his descriptions of an excavation have the artistry of a well-crafted murder mystery, and an audience of laymen is kept breathlessly alert awaiting the discovery of an artifact which will reveal the true identity of an ancient civilisation or the cataclysmic event which brought about its destruction.

Yadin's archaeology programme features a "Find of the Month" and other recent discoveries as well as new interpretations of previously unearthed objects. One of the latter, which Yadin showed viewers on his last telecast, was a 6,000-year-old vessel with "beaks" which, until recently, had been called a "bird-like utensil" for want of a better term. Now, he explained, archaeologists have discovered its real purpose by taking a close look at the "food technology" of contemporary bedouin. As a film sequence convincingly demonstrated, the bedouin use a very similar container to make cheese and other processed milk products, which means, almost certainly, that the "bird-like utensil" was an ancient churn.

Another regular feature of the series, "Archaeology Around the Corner", highlights the fact that almost every Israeli town and village has one or more sites of interest. Yadin recently zeroed in on a site in West Jerusalem, where a partially exposed column, lying flat, is clearly visible A camera team was stationed near the object and then passers-by were asked what it was. Only after several rather comical replies did an interviewee correctly state that it was a column intended for use in the construction of the Second (Herodian) Temple which for some reason had been left lying several miles from the Temple site.

NUCLEAR BRIEF

US export moratorium ?

Proliferation of the international trade in nuclear technology is "very rapidly becoming a major political issue in the United States", Mr Llewellyn King, Editor of *Weekly Energy Report,* told the *Financial Times* conference on nuclear power last week. Hearings set for July 20 on the subject would bring it into the front line, and if proliferation became an issue in the coming elections, he predicted, there would be a "de facto moratorium on the export of nuclear technology", a change which would affect the world nuclear market. The issue was a "lively" one in Congress, and the President was "very concerned".

Reprocessing prospects

The prospects for the nuclear fuel reprocessing deal that British Nuclear Fuels Ltd (BNFL) is negotiating with Japan look "very good indeed", and there has been "very good progress" in negotiations with European countries for similar business, according to Mr Con Allday, managing director of the company. The deal, which involves BNFL's reprocessing facility at Windscale, attracted a good deal of publicity earlier this year, since when the French firm Cogema has been introduced on one side and changes have occurred in the team on the Japanese side. An Anglo-French mission recently visited Japan for talks.

Uranium fix

Canada is resisting the efforts of the US Justice Department, which has served subpoenas on two of the country's three major uranium producers, to investigate alleged attempts at price fixing. The chairman of one of the companies is also president of the Uranium Institute, the trade association representing the industry's producers and consumers which recently held its first annual general meeting in London. It has not been served with a subpoena, and stresses that its activity does not and would not include price fixing. Several companies in the United States have also been served with subpoenas.

Nature conservation

KENNETH MELLANBY

THE pressures on Britain's countryside increase, and so do the efforts of those concerned with wildlife conservation. Since the 1939–45 War, 146 National Nature Reserves covering nearly 120 thousand hectares have been designated, and voluntary organisations such as the Royal Society for the Protection of Birds, the National Trust, and the County Naturalists Trusts have obtained control of only slightly less ground. In these days of world shortages, and the need to produce more food in Britain to reduce imports and the balance of payments deficit, there is concern as to whether it is right to set aside so much land for the benefit of the minority of the population interested in our native animals and plants.

At a meeting recently organised by the Royal Society on the scientific aspects of nature conservation in Britain, two main topics were discussed. The first was the value of conservation as such; the second concerned the contribution of science, particularly ecology, to conservation and the management of nature reserves and other protected areas.

The conservation of the land, of water and of natural resources is clearly desirable, and wildlife may be looked upon as just another "resource". The difficulty is to give this a value, particularly a cash value. Many of the arguments about the economic importance of wildlife are unconvincing to the layman, and may prove counterproductive. It is true that several wild birds and plants may act as inexpensive and delicate indicators of pollution, but the important species are not confined to nature reserves. Wild plants have proved valuable in work in producing new crops, but it is difficult to argue convincingly that the gene pool of the Spring Gentian in upper Teesdale has a contribution to make to food production.

It is safer to base one's support for wildlife conservation on scientific, educational, cultural, aesthetic, recreational or even sentimental grounds. The scientific argument would perhaps appear to be the strongest, but even here the conservationist must not appear to claim too much. Nature reserves provide essential facilities for ecological research, and so make an important contribution to that science However, we may become involved in a circular argument: reserves are provided for research, which yield results which enable us to maintain those reserves so that they continue to provide facilities for more research. To the sceptic this may sound too much like "jobs for the boys". I believe that we conservationists should be honest, and admit that our motivation is not, mainly, economic. We should not be ashamed to admit that our interests are, at least partly, aesthetic and sentimental, and that we believe that conservation contributes to civilised living.

But if we do not claim that conservation is of economic importance, what do we say to those who complain that we are harming agriculture? Could not the quarter of a million hectares in different types of reserves be better used by our farmers? First, it should be noted that only a tiny fraction of these reserves is grade 1 or grade 2 farm land, suitable for arable cultivation. Secondly, we lose vastly greater areas, often of the best land, to housing, factories, motorways and airports. This loss now amounts to 30 thousand hectares a year; in four years the loss in area exceeds that of the 146 National Nature Reserves. The first priority should be to reduce, and eventually stop, this continuing erosion of our farmland.

In the meantime, conservationists are surely right in trying to acquire as many sites as possible. Modern farming, to be profitable, cannot afford to support wildlife except in marginal areas. We need reserves where wildlife has priority, and some areas should be on good farmland, which supports larger numbers of more species than the barren moors generally left to the conservationist. We certainly need to produce more food, but first let us cut out waste. Nearly a quarter of the food bought in our supermarkets ends up in our dustbins, and intensive livestock rearing wastes over ninety per cent of the rations fed. So long as these processes continue, conservationists need have few qualms when they designate new reserves, particularly as this land, unlike that used by industry, could easily be brought into fruitful cultivation in an emergency.

Electrostatic energy storage

SIR,—With shortages of oil and petrol clearly facing us, it is time to consider all other ways of storing energy effectively Although leading possibilities for automotive use include advanced electric batteries and specially designed flywheels, the search for materials (particularly polymers) with high dielectric strength and static dielectric constant must not be overlooked; it might lead to economically attractive electrostatic storage systems.

The efficiency in converting the stored electric energy to mechanical energy to turn wheels can confidently be expected to be very high—close to 90%. This means that substantially less energy (about 1/7) need be stored in a vehicle for range, speed and acceleration on a par with a petrol-burning system. There is no exhaust to pollute the air and even thermal pollution by wasted heat is reduced by a factor of 9 or so at the vehicle. Recharging can be done more rapidly and efficiently than conventional battery charging: a few minutes should suffice at a service station equipped with suitable rectifying equipment and electricity supply lines of industrial capacity. Alternatively, the domestic electricity supply is generally adequate for overnight charging. With programmed parallel–series switching the variation in operating voltage can be kept modest and the extraction of stored energy can be made nearly complete.

The stored energy density in a sheet of dielectric can be expressed as

$$D = 0.4427\times 10^{6}\, Ka^{2}$$

with D in kJ m^{-3} and a in V Å^{-1}; K is the low frequency dielectric constant. Many commonly used capacitor dielectrics have dielectric constants below 10, corresponding to strong ionic or more often to non-polar interatomic bonds. A class of metal titanate ceramics, however, has dielectric constants up to 12,000. But the dielectric strength is the more critical parameter and is sharply reduced by various impurities. In paper-thin sheets, appropriate to capacitor construction, high purity can be achieved in mica ($a\simeq 0.022$) and organic polymers ($a\lesssim 0.028$).

Applying the energy storage formula for mica with a dielectric constant of ~5 to 7, we might expect a storage capacity of 1,000–1,500 kJ per m^3 of mica. Commercial energy storage capacitors are listed up to 600 kJ m^{-3}, based on a waxed paper dielectric, so this level of energy density is close to commercial practice. Recognising that there will be some additional volume required for the thin electrodes and an outer casing, a comparable organic polymer capacitor should have approximately the density of water, and thus an energy density of 1–2 kJ kg^{-1}.

If we take the lead-acid storage battery, at 44 kJ kg^{-1}, as an aiming point, we would need to develop a material with the dielectric strength of the best plastic, incorporating enough polarisable sites to raise the dielectric constant above 130. This is a reasonable aim in economic terms as the lead-acid battery is already marginally adequate for electric cars and trucks.

A further discussion of promising materials and ideas for study has been prepared (ORNL Report TM-29, June 1976).

Yours faithfully,

Electrostatic energy discharge from humans

SIR,—The amount of electrostatic energy which can be stored in the capacitance represented by the human body does not appear to have been measured and reported in the literature. Besides being of phenomenological interest, this measurement could be important when considering the explosion hazard represented by anaesthetics and antiseptics when used in close proximity to electrostatically charged humans, such as in operating theatres and intensive care areas. In this regard, it has been suggested that ether vapour will explode when subjected to an electrostatic energy as small as 200 μjoules in magnitude.

An appreciation for the magnitude of the electrostatic voltage which the human body can be charged to; the capacitance represented by the human form; and the electrostatic energy stored by humans, can be obtained by discharging the body through a known resistance, and displaying the discharge curve on a storage oscilloscope.

The results obtained indicate that the electrostatic energy which the human body can store, and consequently dissipate, is in the order of 6.46±3.26 millijoules. The capacitance of the body is 65.9±12.1 pf, and the electrostatic voltages which the body can be charged to is 13,802±4,443 volts These measurements could be valuable when considering the role that the human body plays in the causing of explosions of volatile chemicals in hospital and industrial environments.

Yours faithfully,

A. E. MARBLE
D. MACVICAR

Competition 8

Du Pont's notepaper has "There's a world of things we're doing something about" imprinted on it, and the slogan for Rockwell International is "Where science gets down to business".

A prize of £10 is offered for the best one-sentence slogan (preferably tongue in cheek) for your (or anyone else's) laboratory, business or university The closing date for entries is August 31.

Competition 7 requested a modern headline for a scientific achievement, and there was a large entry, on fairly predictable themes. A. L. Mackay (London) receives honourable mention for "Prominent philosopher in public bath scandal". The £10 prize is shared equally between P. J. Fallon (London), for "Role of Earth probed by Pole", and C. F. Hammer (Wilmington, Delaware), whose "Bell discovers new use for wooden poles—wires to carry conversation over distances" seemed just right for the *New York Times.*

news and views

Interpreting protein electron density maps

from C. C. F. Blake

EVER since the subject began, protein crystallographers have been complaining that they work for a long time on a project without obtaining any significant information and then, literally overnight, they are overwhelmed with information The source of this surfeit of data is the electron density map of the protein which is calculated in the form of a three dimensional figure-field of electron density values that contains between 50,000 and 500,000 points, depending on the size of the protein and the resolution of the study. Although the figure-field will encompass one protein molecule, much of the data is redundant because it will inevitably include some volumes of liquid containing more or less-ordered water molecules, and parts of other (identical) protein molecules related by symmetry or simple translation to the central molecule.

In view of the vast amount of information present in the figure-field, total interpretation is not normally attempted, attention being naturally concentrated on the folding of the polypeptide chain and the location of side chains. This operation has always been carried out in the past by converting the figure-field into a stack of transparent sheets contoured in levels of equal electron density, and interpreted in terms of a physical molecular model This is, however, by no means straightforward, especially if an accurate model is required, because the ideal of building the model inside the electron density is a physical impossibility. After various laborious *ad hoc* methods had been used on the first proteins, a standard piece of apparatus—the optical comparator—was proposed by Richards (*J. molec. Biol*, **37**, 255, 1968), using the ingenious principle of optical superposition of the model and the contoured electron density map Although it is relatively easy to use, the comparator has certain disadvantages it is large and uses up valuable laboratory space; with larger proteins it becomes physically difficult to build the model, and some users have had difficulty with depth perception. Another problem associated with all physical models, however they are built, is the need to measure the spatial coordinates of all non-hydrogen atoms, a laborious process requiring some thousands to tens of thousands of accurate measurements. These coordinates are then returned to the computer, either for drawings to illustrate the structure, or for some kind of refinement process for improving their accuracy.

Since the current system requires very hard work to obtain a somewhat inaccurate model it seems desirable to seek an improved system, which clearly has to be computer based The most obvious improvement is to use a computer display system as an electronic Richards' comparator, as proposed by Katz and Levinthal (*A. Rev. Biophys. Bioengng*, **1**, 465–504; 1972). This requires expensive hardware and allows only a limited section of the map to be displayed for fitting at any one time. An alternative is to use the basic computer to attempt the appropriate pattern recognition on the figure-field in an automated or semi-automated procedure. This approach, whose development has been reported by Greer in a series of papers (Greer, *J molec. Biol.*, **82**, 279; 1974; **98**, 649; 1975; **100**, 427; 1976) has now reached the point where it has been used successfully to trace the main chain and produce a preliminary set of atomic coordinates of a Bence-Jones protein (Greer, *J. molec. Biol.*, **104**, 371; 1976)

The basic aim of Greer's approach is to reduce the electron density to a series of thin connected lines that trace the path of the polypeptide chain. Although the path of the polypeptide chain will be marked by a continuous string of above average density, in any real protein map it is by no means uniquely defined. Variation in thermal vibrations and possibly even of order will cause the level of the string of density to be quite variable, while disulphide bridges and strong intramolecular or intermolecular hydrogen-bond contacts will result in strong continuous features that do not represent the path of the main chain. These factors result in formidable problems in attempting to recognise and isolate the true main-chain density from these other similar, but spurious features, and Greer has had to develop a procedure that has a number of stages in each of which criteria have been evolved that successively eliminate density points which do not represent the main chain

The starting material is the electron density figure-field in a Cartesian coordinate system with a grid spacing of about 1 Å, that completely encloses a single molecule. The first operation is the elimination of all electron density points below a minimum value and "contouring" the remainder at equal intervals. The appropriate values are arrived at by inspection to give maximum main-chain continuity and a minimum of spurious cross connections. Starting with the lowest contour level, the remaining points are successively removed to leave a skeleton of lines that defines the basic connectivity in the map, using a three-dimensional generalisation of a method developed for processing micrographs of chromosome smears. This skeleton is then simplified by pruning easily distinguishable side chains down to the main chain, leaving a flag to mark the position of the α-carbon atoms At this point the description of the skeleton is transformed into a tree-like structure in which segments are defined as lines that lie between the tips or branch points in the skeleton; such a description restricts ambiguities to the points where segments meet. After this, all segments that represent parts of neighbouring molecules that obtrude into the Cartesian frame are removed to isolate a single molecule Simple loops in the skeleton are removed next by using simple rules to identify the true main-chain branch. The skeleton that remains represents primarily the main-chain and inter-main-chain bridges, possibly lacking one or two main-chain connections that were removed earlier. The final stage involves putting the skeleton through a process that selects the main chain on the basis of length and the presence of side chains, starting with the longest segment and attempting to add other segments to each end. This is an iterative procedure that includes examining skeletons calculated at lower electron density to locate weak main-chain connections eliminated from the main skeleton. Wisely, manual intervention is allowed for when the programme reaches an ambiguity that cannot be resolved easily.

Using the procedure on a 3-Å resolution map of the Bence-Jones protein Rhe, Greer has shown that it defined a main-chain line some 433 Å long, produced provisional coordinates for 113 α-carbon atoms, defined the basic β-sheet structure characteristic of Bence-Jones proteins and also found a short segment of α-helix. Even at this stage it is clear that the technique could be valuable and it seems probable that it can be developed further. Although some crystallographers will see this as a further encroachment of the computer into what they consider to be their proper province, most will note its real value in giving more time (and possibly a better start), for the important task of getting an accurate description of the molecule through which the biological problems can be solved. □

Hydrogenases and efficiency of nitrogen fixation in aerobes

from R. O. D. Dixon

WITH the high energy, and thus financial, cost of nitrogen fertilisers it is now important to rely, where possible, on microbial nitrogen fixation. The fixation of nitrogen by microorganisms occurs with varying efficiency in terms of substrate consumed for each nitrogen fixed. To use microorganisms to the best advantage it is well that we be able to identify factors which lead to greater efficiency of nitrogen fixation and thus to select the most efficient organisms.

It is known that metabolic energy in the form of ATP and reducing power is wasted, by the enzyme nitrogenase reducing protons rather than nitrogen. Evolution of hydrogen occurs with nitrogenase from all nitrogen-fixing microorganisms tested so far *in vitro*, although it has not been possible to test the extent to which this wastage occurs *in vivo* in most organisms because of the complicating presence of hydrogenases. In anaerobic organisms there is a hydrogenase which evolves hydrogen simultaneously with the nitrogenase whereas in aerobes, such as *Azotobacter*, hydrogen is taken up by a hydrogenase.

In experiments in which it was thought that the hydrogenase had been inhibited by carbon monoxide, no hydrogen evolution was detected from *Azotobacter*. It was thus suggested that, in this organism, the nitrogenase, atypically, did not reduce protons (Postgate, in *The Chemistry and Biochemistry of Nitrogen Fixation*, 161–190, Plenum, New York, 1971). This view, which was not universally accepted, has now been shown to be erroneous by Smith, Hill and Yates (page 209 of this issue of *Nature*) who report that the *Azotobacter* nitrogenase does not in fact differ *in vivo*, from that of the other nitrogen fixers. They confirm that the lack of hydrogen evolution from intact bacteria is due to hydrogen uptake by a hydrogenase.

That the hydrogen, taken up by the hydrogenase, may be put to some use was shown some time ago by Hyndman *et al.* (*J. Bact.*, **65**, 522–531; 1953). They showed that the hydrogen taken up by *Azotobacter* was oxidised with consequent synthesis of ATP. Similar observations were made more recently with hydrogenase in *Rhizobium* bacteroids (Dixon, *Arch. Mikrobiol.*, **85**, 193–201; 1972). Possession of this hydrogenase enables these aerobic organisms to recoup some of the ATP expended on wasteful evolution of hydrogen by nitrogenase. The suggestion was made earlier (Dixon, in *Nitrogen Fixation by Free-living Microorganisms* (edit. by Stewart, W.D.P.), Cambridge University Press, 1975), and is now reiterated by Smith *et al.*, that this reutilisation of hydrogen with ATP formation is the reason for the greater efficiency which has been found for *Azotobacter* nitrogen fixation over that of anaerobes such as *Clostridium* (Hill, Drozd, and Postgate, *J. appl Chem. Biotechnol.*, **22**, 541–558; 1972).

Although the presence of hydrogenases in free living organisms has precluded the investigation of the level of wastage by the evolution of hydrogen, the lack of hydrogenase in some root nodule associations has enabled Schubert and Evans (*Proc. natn. Acad. Sci. U.S.A.*, **73**, 1207–1211; 1976) to estimate the degree of efficiency of the fixation of nitrogen in a number of such associations. The more efficient associations, which included all the non-legume root nodules in the study, showed evidence of a hydrogenase which takes up the hydrogen evolved. The wastage of ATP and reducing power by evolution of hydrogen is estimated to vary between 40 and 60% of the total used by nitrogenase in those associations in which hydrogenase was not a complicating factor.

Schubert and Evans calculate that with a wastage of 50%, reutilisation of hydrogen could double the amount of nitrogen fixed in cases where the energy supply is limiting. It has indeed been demonstrated in a number of cases that the supply of photosynthate from the plant limits nitrogen fixation by root nodules. Although this calculation would seem to be optimistic, if one bears in mind that the estimate of molecules of ATP utilised, per pair of electrons transferred through nitrogenase for hydrogen evolution, is three to four and the P/O ratio obtained from hydrogen uptake is not likely to be better than two, substantial savings can be made. This would be reflected, as Schubert and Evans point out, either in an increase in dry matter yield, where photosynthate is not limiting, or in an increase in nitrogen fixed. Thus selection of a strain of *Rhizobium* which possesses this hydrogenase may pay dividends in the yields of some legume crops.

Much work has been done and is being pursued on the legume–root nodule association in order to understand the infection process and nodule development, with the long term aim of transferring nodulating capability to other agricultural crops, whereas little attention has been paid to non-legume associations. But the greater efficiency of nitrogen fixation of non-legume associations shown in the data of Schubert and Evans suggests that it may be well to give them more attention than in the past. □

Irregular associations

from E. G. Richards

FOR nearly a decade it has been known that complementary trinucleotides do not associate detectably. So, we may ask, how does the anticodon on the tRNA bind with such specificity to messenger triplets on the ribosome? Part, at least, of the answer must lie in the tRNA, for trinucleotides complementary to anticodons of tRNA associate with the latter and, more dramatically, as Eisinger showed some years ago, pairs of tRNA molecules with complementary anticodons bind together with an association constant as high as 10^6 M^{-1}.

The purist may wonder what relevance the participation of tRNA molecules in these unnatural acts may have to tRNA–messenger interaction but Grosjean, Söll and Crothers have come up with some interesting suggestions (*J. molec. Biol*, **102**, 499; 1976).

When such pairs of tRNA molecules interact, they do so with a small (0.1% of the total) absorbance change which

Regulatory genes in fungi

from a Correspondent

THE paper by Arst in this issue of *Nature* (page 231) marks another step in our understanding of regulation of gene action in the mould *Aspergillus nidulans.* In 1970, Hynes and Pateman (*Molec. gen Genet*, **108**, 97–106, 107–116) reported mutants which identified a gene whose product seemed to act as a positive regulator of the structural gene for amidase (*amdS*). Now Arst reports that this regulatory gene—now called *intA* for integrator—also regulates expression of two genes concerned with ω-amino acid metabolism. These latter two genes, *gatA* and *gabA*, code, respectively, for an inducible transaminase acting on β-alanine, γ-aminobutyrate or δ-aminovalerate and a permease for the same ω-amino acids. The three genes under control are all unlinked to *intA* and to each other. It seems that various mutations in *intA* can affect the control of *amdS, gatA* and *gabA* differentially, and can also be associated with changes in the relative responses to γ-aminobutyrate and β-alanine as effectors. The conclusion is that the *intA* product interacts with each of the three genes (or with controlling regions associated with them) and also with various small molecular effectors, and that these specificities can be altered by mutation. Arst draws attention to the similarity between *intA* and the type of integrator gene proposed by Britten and Davidson in 1969 (*Science,* **165**, 349–357) as part of an influential general model for regulation of gene action in eukaryotes.

Arst's report, together with earlier work, shows that sets of unlinked genes can be simultaneously subject to more than one system of integrative regulation. Arst and Cove and their colleages (for example, *Molec. gen. Genet.*, **126,** 111–141; 1973) had already described in *Aspergillus* a regulator gene, called *areA*, which is concerned with nitrogen catabolite repression, and which regulates the action of several other genes with functions in the generation of ammonium ion. A type of mutant allele, called *areA*^{r}, represses these other genes (including the amidase gene) even in the absence of ammonia. "Constitutive" alleles of *intA* can nullify the repressing effect of *areA*^{r}, the positive integrative control in this case over-riding the negative. In addition, one can have positive gene-specific regulation, acting in parallel with the "integrator" regulation. Thus, another regulatory gene, *amdA,* is found by Arst to act positively on *amdS* (more or less additively with *intA*) with no effect on *gabA* and *gatA*

The regulation of nitrogen metabolism in *Aspergillus,* thanks mainly to the work of J. A. Pateman in Glasgow, Arst (with D. J. Cove and C. Scazzocchio) in Cambridge, M. J. Hynes in Australia and P. Weglenski in Warsaw, is becoming an extremely complex story—excessively so, perhaps, in the opinion of some. But the complexity is there in the eukaryotic cell. Attempts to unravel the network of gene interactions are bound to produce something of a tangle at the outset, but perhaps some general features are beginning to emerge which will eventually fall into place in a higher-order pattern.

Grosjean *et al.* were able to monitor in temperature jump relaxation experiments. This absorbance change shows the right spectral distribution to be expected from the base pairs presumed to be formed, and is not manifest when the two anticodons are not complementary Moreover, the three complementary bases must be centred in the middle of each seven-membered anticodon loop for the reaction to be appreciably manifest. Thus, for interaction, the anticodons *per se* must be complementary, and complementarity between other bits of the anticodon loops does not help.

Returning to the temperature jump results, the authors found that the rate constant for the association reaction was close to that expected for the association of complementary trinucleotides, and, furthermore, virtually temperature independent. The surprise comes in the rate constant for the back dissociation reaction which was six orders of magnitude slower than expected. It follows that the equilibrium constant is 10^6 times higher than expected.

More detailed analysis showed that the entropy of interaction was not very different from that expected for trinucleotide interaction, but the enthalpy change was about −25 kcalories, which is about 10 kcalories larger than expected. This difference of 10 kcalories is sufficient to account for the factor at 10^6 and is at the kernel of the enhanced anticodon–anticodon interaction. This in itself suggested that stacking interactions were involved.

Pushing the investigation further, Grosjean *et al.* studied the interaction of *Escherichia coli* tRNA$^{\text{Glu}}$ with yeast tRNA$^{\text{Phe}}$ in the presence of EDTA, in which conditions the former species is in the denatured conformational state. The association was still observed, suggesting that the structural features which distinguish the two conformer states are not important to the association. Similarly the removal by specific cleavage of the first 16 nucleotides from the 5′ end of the tRNA$^{\text{Phe}}$ did not alter the interaction. On the other hand, fragments obtained from both these species such that anticodon helical arms could not form, still associated but with a constant reduced by about two orders of magnitude—leaving an enhancement of four orders still to be accounted for.

The remaining factors were deemed to reside in the "dangling ends" or the residual four bases in the anticodon loop that are not involved in the anticodon itself Grosjean *et al.* point out that the sixth base in the anticodon loop (that is the one at the 3′ end of the anticodon) is frequently modified. They go on to show that the association constant varies for species with similar anticodons but differs in the nature of the sixth base, and, in particular, that excision of the Y base from this position in tRNA$^{\text{Phe}}$ leads to a substantial reduction in the enthalpy of association.

Grosjean *et al.* tie all these observations together by postulating that the enhanced association constant and the increased enthalpy of association originates from the stacking of the two anticodon arm helices on either side of the helical region formed by the anticodon–anticodon interaction, with the 3′ dangling ends stacked up as jam in this three layer cake. I choose this analogy carefully since jam is well known to be sticky.

We are finally left with the thought that something similar happens in the codon–anticodon interaction. Maybe the ribosome holds the relevant portion of the messenger in a configuration similar to that in the tRNA and allows the interaction to be similarly stabilised by stacking.

These results also imply that the anticodon helical arm exists in both the native and denatured forms of *E. coli* tRNA$^{\text{Glu}}$. Further evidence of the similarities and differences between these two forms of tRNA comes from a paper by Jones, Kearns and Muench (*J. molec Biol.*, **103**, 747; 1976) who worked with *E. coli* tRNA$^{\text{Trp}}$. They measured the low field nuclear magnetic resonance (NMR) spectrum of the native form of this species and assigned to their satisfaction all parts of the 11 5–14.5 p.p.m. region to one or other structural feature expected of the clover leaf model in its surmised tertiary structure. There were thus 19 base pairs, a protected U or G and two tertiary base pairs including A_{14}–s^4U_8. The agreement between their experimental spectrum and that computed from these assignments was very reasonable. They then repeated the process for the denatured form and considered in detail the difference NMR spectrum between the two. They succeeded again in demonstrating a reasonable agreement between calculated and experimental spectra. The final result is a model for the denatured form in which stem, TUC arm and anticodon arm remain intact but the DiHU arm is undone and the anticodon arm extended by some of the original DiHU arm bases pairing with bases in the extra arm. This extension of four base-pairs involves one bulged out G. This model they argue is also consistent with the pattern of kethoxylation of both the native and denatured forms. In an argument too complex to repeat here they also consider and reject other possible pairing schemes for the denatured form.

Besides being consistent with their own data the model for the denatured form has several attractions. The small number of base pairs that needs to be undone for either form to revert to the other is consistent with the ease of this interconversion. Furthermore, if it is assumed that *E. coli* tRNA^{Trp} has a tertiary structure similar to that of yeast tRNA^{Phe} as vouchsafed by X-ray diffraction analysis, then this interconversion can be readily envisaged to occur with but minimal disruption of the tertiary structure.

If all this is accepted we can begin to point at those parts of the structure that are involved in the biological activities that are knocked out when the molecule is denatured. □

Meteoroid swarms colliding with the Moon

from David W. Hughes

METEORIC dust particles are continually striking the Moon with velocities between 2.4 and 74 km s^{-1}. On impact they lose their considerable kinetic energy and excavate a crater thus producing a large quantity of hot ejector most of which subsequently falls back to the lunar surface but some of which exceeds the escape velocity and moves off into space. A lunar seismic disturbance is also produced. The latter can be detected by the passive seismic network deployed by the Apollo astronauts. This consists of four stations arranged around an approximately equilateral triangle with sides about 1,100 km long. The Apollo 15 seismometer makes the northern apex at Hadley-Appenines, Apollo 16 is in the east in the crater Descartes, and the west apex has Apollo 12 in Oceanus Procellarum and, 180 km away, Apollo 14 at Fra Mauro. Each station has three long period (>1 s) seismometers, sensitive to motion along three orthogonal directions, and a fourth short period (<1 s) seismometer sensitive to vertical motion. Each can detect a ground movement of about 0.05 nm.

Fortunately lunar scientists think that the seismic signals produced by meteoroid impacts can be distinguished from those caused by moonquakes. Impact events have sharper first signal rise times, indistinct shear wave arrivals and lower frequencies in the wave train. This is due to the fact that the impact waves must traverse the surface scattering zone twice between the impact point and the seismometer. Moonquakes, caused by tectonic strains within the lunar interior cross the zone only once so the energy in their seismic wave is less diffuse.

During the 924 days between January 1, 1973 and July 13, 1975 the seismic network detected 815 signals interpreted as being caused by meteoroid impacts. These have been statistically analysed by Duennebier, Nakamura, Latham and Dorman (Geophysics Laboratory, University of Texas) in their recent paper in *Science* (**192**, 1000; 1976). If an event is detected at only one seismometer it is regarded as "small". The signal amplitude is probably proportional to $E^{1/2}/r$ where E is the energy of the meteoroid and r is the distance between the sensor and the impact point, so most of the small events are caused by impacting particles with masses between 50 and 10^3 g, the larger events, detected at two or more stations, being caused by 5×10^3 to 5×10^4 g meteoroids. The authors find that a plot of impact rate as a function of time shows several sharp peaks in activity. Also, the frequency of intervals where there are no impacts is significantly more than expected—expected, that is, if the meteoroids are scattered randomly in space and the resultant impact rates follow a binomial distribution. Duennebier *et al.* conclude that some of the objects in the 50 to 50,000 g size range are not distributed randomly in space but occur in swarms. One of the more impressive swarms detected by the network was estimated to be about 2×10^7 km across and have a total mass between 10^{13} and 10^{14} g.

Could these peaks in the rate curve be caused by the Moon passing through a stream of particles produced by a decaying or decayed comet? Meteor showers caused by just such a process are common on Earth. The problem is that only about 10% of the mass in a meteor stream is made up of particles with individual masses over 50 g (according to Hughes, *Space Res* XV, 565; 1975). A considerably smaller percentage of the sporadic Solar System dust cloud is made up of these large particles, however, so the meteor streams should stand out prominently above the background Now 50 and 50,000 g particles impacting with the Earth's upper atmosphere at around 40 km s^{-1} produce visual meteors of magnitude about −4 and −12 respectively and an increase in flux of these very bright meteors and fireballs has been noticed during meteor showers. Meteor streams are always detected from Earth at the same solar longitude (about the same time each year) and Duennebier *et al.* note that the lunar events show no yearly pattern. The fact that the Moon oscillates by 3.8×10^5 km about the Earth's orbit does not help to get over this problem as meteor streams such as the Perseids and Geminids are 2.0×10^6 and 1.0×10^6 km wide. Both these streams are rich in fireballs.

It was also noticed that the mass distribution of the incident particles changed during the high rate events, the percentage of smaller objects being larger in the swarms than during the normal sporadic influx. Unfortunately this is exactly the opposite to what is observed with visual meteor showers, where the percentage of large particles increases.

Two of the maxima occurred on consecutive months, near new Moon, whereas the June, 1975 maxima occurred at full Moon. This contrasts with the timing of the moonquakes observed at the Apollo 17 site (Cooper and Kovach, *Proc. Lunar Sci. Conf 6th*, 2863; 1975) which appear to be closely correlated with the 29-d lunar month and the 300 K temperature variation of the lunar surface layer that occurs between mid-day and midnight.

So these data reveal something of a mystery. Large moonquake rates result, according to the authors, from the impact with the Moon of swarms of particles with masses greater than 50 g. Should similar swarms be seen on Earth? The answer is no, because even the peak lunar activity only corresponds to an infall of one large meteoroid every 3 days over an area 100 km in radius. The converse though is puzzling. The annual meteor streams seen on Earth contain a significant flux of particles in the mass range supposedly detected on the Moon. This flux also exceeds the sporadic (non-shower) flux by nearly an order of magnitude. So why haven't these been observed in lunar seismic data? Using the influx rates for the large meteoroids which produce fireballs in the Earth's atmosphere, obtained from the American Prairie Network of all-sky cameras (McCrosky and Ceplecha in *Meteorite Res*, 600 (edit. by Milman, P.,) D. Reidel, Dordrecht, 1969), about

250 particles with masses greater than 50 g should hit the Moon each day. Even going to the upper limit (50,000 g), of Duennebier *et al.*'s mass range the rate is about 10 per day. This compares with the maximum rate of 12 events per day observed by the seismic network. If meteoroid impacts are being detected the major meteor showers should stand out clearly above the sporadic background. The fact that Duennebier *et al.* are not seeing these showers introduces the possibility that they are seeing something else. ☐

Metals in proteins

from S. D. Dover

THE environment of metals in metalloproteins is of growing interest with the advent of synchrotron radiation. As distinct from crystallographic studies, which reveal the whole molecule, X-ray absorption measurements in the neighbourhood of the absorption edge of a metal are indicative of the local environment.

The use of synchrotron radiation as a tool for studying that environment is probably at the beginning of its exponential growth phase. In this application a tunable source of X radiation is required so that the spectrum can be observed. Coventional tubes are designed to emit most of their X-ray energy in the characteristic radiation line. The white radiation background, for a similar wavelength spread, has a much lower intensity. This means that the power available from the synchrotron over a whole range of wavelengths is several orders of magnitude greater than from laboratory sources.

This factor makes it possible to measure in an acceptable time the X-ray absorption spectra of systems where the absorber is relatively dilute (as in metalloproteins). Results from the Stanford Synchrotron Radiation Project (SPEAR) have been reported (*Proc natn. Acad. Sci. U.S.A.*, **72,** 2340; 1975) where gains in speed of 10^4–10^5 over X-ray tubes have been obtained. For example, the spectrum for haemoglobin over a 400 eV range was measured at 1 eV steps in only 20 h. This gave an acceptably low noise compared with the modulation of the X-ray absorption.

It is the modulation of the absorption spectrum that is of interest. The spectrum of a free metal consists of a low absorption region below the absorption edge where the incident photon is insufficiently energetic to excite the K electron. With increasing energy of X rays, the absorption edge is reached as the K electron can be excited to empty bound states. Beyond the edge itself the photon energy is sufficient to cause the emission of a photoelectron. The absorption tends to decrease monotonically from the absorption edge.

In contrast the spectrum of a bound metal in this region (the region of the extended X-ray absorption fine structure, EXAFS) is affected by the photoelectron being scattered back to the metal emitter by neighbouring atoms, inhibiting absorption. Instead of decreasing monotonically, the spectrum is modulated as the wavelength of the photoelectron varies with the wavelength of the X-ray photon. It is as if the photoelectron is acting as a diffraction probe for the environment of the metal. The back-scattering from surrounding atoms will have the appearance of interference fringes according to their distances from the metal and the photoelectron wavelength. Theoretical analysis of the fine structure of the spectrum has been successful in terms of the atomic environment for metals themselves (*Adv. X-ray Anal*, **13,** 248; 1970) and the iron-sulphur system in rubredoxin (*Proc. natn. Acad. Sci. U S.A.*, **72,** 4003; 1975). Work is continuing on haemoglobin and metalloporphyrins (*Proc. natn. Acad. Sci. U.S.A.*, **72,** 2340; 1975) where the results from the porphyrins can be used in the interpretation of the environment of the haem iron.

The absorption edge itself is being studied in model compounds (*Proc. natn Acad. Sci. U.S.A.*, **73,** 1384; 1976) where the fine structure and position is affected by the available bound electronic states. These and other model compound studies together with those of metalloproteins provide the possibility of examining the electronic situation of metals in proteins, and the two regions of the X-ray absorption spectrum together hold the promise of revealing the whole local environment. ☐

Fission of medium weight nuclei

from P E. Hodgson

THE fission of heavy nuclei such as uranium and plutonium is a well known phenomenon of practical importance. In special circumstances lighter nuclei can also undergo fission, and evidence for the fission of nuclei of mass around 80 has recently been found by Braun-Munzinger and colleagues (*Phys. Rev. Lett.*, **36,** 849; 1976).

The experiment giving evidence of such fission is the interaction of 140 MeV ^{32}S ions with ^{50}Ti. This type of interaction has been studied for many years in order to determine the characteristics of heavy ion reactions, but the particular feature of the new experiment is an array of electronic counters that facilitates determination of the masses and energies of two of the products of the reaction. For

The cytonet protein

IN his report on the recent EMBO symposium, Bretscher (*Nature*, **261,** 336; 1976) refers to the protein which Pearse (*J. molec. Biol.*, **97,** 93; 1975; *Proc. natn. Acad. Sci. U.S.A.*, **73,** 1255; 1976) has shown to be associated with vesicle "coats". In separate publications on this same material in the biochemical and neuroanatomical literature, an important correlation appears to have gone unnoticed. Gray (*J. Neurocytol.*, **1,** 363; 1972; *Brain Res.*, **62,** 329; 1973) examined coated vesicles in presynaptic terminals in the central nervous system and concluded that the coat material is structurally indistinguishable from a fibrous network filling the intervesicular cytoplasm. He also noticed that coated vesicles are surrounded by a clear space which he interprets as a retraction zone caused by fracture of an extensive cytoplasmic network, part of which has artefactually collapsed onto the vesicle forming the coat. The coat then appears to be a distorted fragment of a diffuse yet discrete cytoplasmic organelle composed of a fibrous reticulum which Gray called the 'cytonet'.

Gray (*J. Neurocytol.*, **4,** 315; 1975) later repudiated not only vesicular coats but the entire cytonet structure as artefactual, thinking it to be composed of denatured protein complexes. However, Pearse's discovery that vesicular coats contain essentially one protein supports an interpretation of the cytonet as a distinct supramolecular structure. Since it pervades the cytoplasm of many cell types it seems likely to play some role in the spatial organisation of cytoplasmic components, particularly of organelles such as synaptic vesicles. It thus seems important that the protein which coats isolated vesicles should be considered in its broader association with the cytonet, rather than in the limited context of "coated vesicles" which subcellular fraction studies imply Pearse's proposed name for this protein (clathrin or "coat substance") is a misnomer. If the molecule must have a name 'cytonexin' would be better.

A. J. MATUS

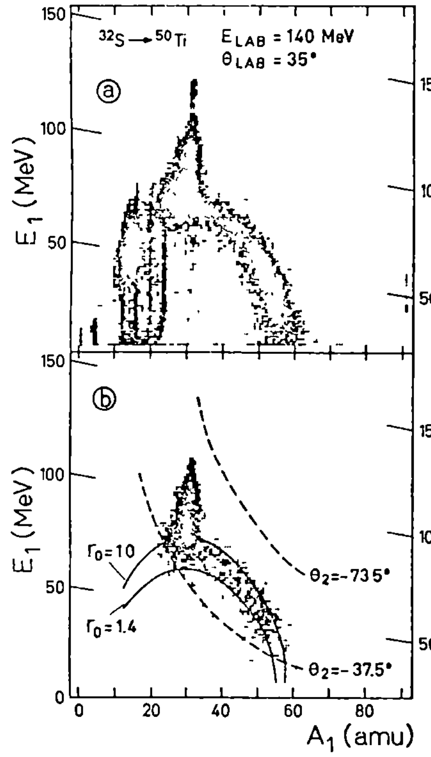

Fig. 1 Plot of the energy and mass number of particles emitted from the interaction of 140 MeV ^{32}S with ^{50}Ti. The top diagram shows all particles and the lower one only those emitted in coincidence with a second particle entering an ionisation chamber. The solid lines are calculated for the electrostatic repulsion of two spheres and the dashed lines are the kinematic constraints due to the detector geometry.

each interaction it is possible to measure the energy (E_1) and mass (A_1) of one of the reaction products by a time-of-flight telescope set at 35° to the incident beam and then the energy and energy loss in an ionisation chamber of a second particle emitted on the opposite side of the beam at the same time as the first, together with its angles of emission in and normal to the scattering plane.

Some of the results are shown in the figure in which each point represents a particle of energy E_1 and mass A_1 detected by the time-of-flight telescope. The top part shows all particles and the lower part only those emitted in coincidence with a second particle entering the ionisation chamber.

In these plots, the vertical lines around $A = 32$ correspond to the incident ^{32}S ions that have undergone peripheral elastic or quasielastic interactions with the loss or gain of a few nucleons. These interactions have been extensively studied and are now quite well understood. The broad band of points extending from $A \approx 32$ to $A \approx 50$ corresponds mostly to particles coming from the fission of the compound nucleus with $A \lesssim 82$ into two fragments of similar mass.

This identification is made by calculating the kinetic energies for the electrostatic repulsion of two charged spheres separated by $\{r_0(A_1^{1/3}+A_2^{1/3})+2\}$ fm for $r_0 = 1.0$ and 1.4; with the lighter fragments following the stability valley. The results of this calculation are shown by the solid lines in the figure, and they follow the experimental distribution very well.

Confirmation of this comes from the identification and kinematic correlations of the coincident particles. The ionisation chamber measurements of the second particle give its charge Z_2, and assuming its mass is $A_2 = 2Z_2+1$, the total mass of the fissioning nucleus is A_1+A_2. For all values of Z_2 between 12 and 16 the average value of A_1+A_2 is between 78.2 and 79.2 compared with the known total $A = 82$. This indicates that on the average about three nucleons are lost in the reaction. The mass distribution of the fission products is uniform from $A \approx 35$ to $A \approx 55$.

Additional studies of the energy distributions of the secondary particles also confirmed that fission had taken place. The correlation between A_1 and the angle of emission of the second particle showed that several nucleons are evaporated during the reaction, but it was not possible to distinguish between nucleons emitted before or after the fission process.

This experiment gives the first definite evidence for fission in this mass region and provides a way of studying the fission dynamics of highly excited nuclei with large angular momenta. ☐

Suspicious husbands

by John Krebs

On evolutionary grounds we would expect husbands to be suspicious. If a male is about to spend considerable time and effort in helping his mate to rear young he ought (in evolutionary terms) to check carefully that the young carry his genes. Male lions and langurs may even go to the extreme of killing off all the extant babies when they first take over a new harem: this ensures that the females will only rear children of the new group leader. The female herself, being equally related to her offspring regardless of the father, is not necessarily averse to infidelity.

While one can easily amuse oneself by developing such arguments as the logical outcome of the rules of natural selection (and perhaps even speculate on human analogies) it is not often that one comes across an experimental test. However, Erickson and Zenone (*Science*, **192**, 1353–54; 1976) have recently shown that male ring doves behave exactly as predicted by the theory.

The male ring dove shares with his mate the parental duties of nest building, incubation, and feeding the young, and so should be suspicious of a female which might have been inseminated by another male. The basis of Erickson and Zenone's experiment was the well established observation that male courtship displays have an important effect in stimulating ovarian activity. After a certain amount of courtship from a male, the female ring dove secretes ovarian steroids which cause her to start the so-called nest soliciting display, indicating her readiness to build a nest. Erickson and Zenone tested the reaction of 35 males to two groups of females: one that had been pre-exposed to courting males and brought into nesting condition, and one that had been kept in isolation. The first group of females immediately started nest soliciting when brought into contact with the test males, while the others did not. The reaction of the males was clear: they showed more aggression and less courtship towards the 'sexed up' females. Thus, as the theory predicts, males were suspicious of females that gave away the fact that they had been consorting with other males, and could have been fertilised by them. ☐

Haemopoiesis discussed

from J. J. T Owen

A symposium on Haemopoiesis in Vertebrate Embryos was held at the Institut d'Embryologie, Nogent-sur-Marne, France, on June 14–16. It was sponsored by the Delegation Generale à la Recherche Scientifique et Technique, Centre National de la Recherche Scientifique and the International Society of Developmental Biologists.

Many meetings these days seem to concentrate on highly specialist topics; perhaps it may be said that we learn more and more about less and less. This meeting was different and the organising committee should be congratulated on getting together scientists from various disciplines including embryology, immunology and haematology.

E. Cooper (Los Angeles) opened the meeting with an account of the evolution of blood cells and pointed out that the most primitive blood cell, a protohaemocyte, was involved in phagocytosis and nutrition. A lively debate followed about the origins of haemopoietic stem cells during ontogeny—an important topic that has generated a good deal of heat since the days o Maximow In particular, the origins thymus lymphocytes attracted spe interest—do they arise from the thymic rudiment itself or from blood-borne stem cells? E. P. Volpe (Tulane University) and N. Cohen (Basel) argued that experiments in which tissue primordia were transplanted between frog embryos of different ploidy states, proved that thymus lymphocytes are derived by differentiation of cells intrinsic to the thymic rudiment itself. Furthermore, Volpe suggested that a similar situation may exist in birds and mammals. But the elegant transplantation experiments of N. Le Douarin and her colleagues (Nogent-sur-Marne), using the structural differences between quail and chick nuclei as markers, demonstrate clearly that lymphocytes of the thymus and the bursa of Fabricius are derived from blood-borne stem cells. In addition, P. Deparis and A. Jaylet (Toulouse) and J. Charlemagne (Paris) presented evidence that thymus lymphocytes of newts and salamanders are of blood-borne origin. Hence, either there are fundamental differences in the pattern of lymphopoiesis among amphibia or, perhaps more likely, there is a common phylogenetic pattern involving migration of blood-borne stem cells to organs such as thymus. Volpe's results are compatible with the latter notion if stem cell migration occurs early in ontogeny and is restricted in time, as demonstrated by Le Douarin.

The source of blood-borne stem cells was also debated. It has been suggested that all haemopoietic stem cells are derived from yolk sac (Moore and Metcalfe, *Br. J. Haematol.* **18,** 279; 1970). F. Dieterlen-Lievre (Nogent-sur-Marne), however, demonstrated convincingly for the first time that definitive erythropoietic stem cells are derived from other sources. Yolk sac cells can populate the thymus, but they probably require a previous sojourn in the bone marrow (O. Stutman, New York).

The remarkable sequence of cellular and biochemical events which occurs during embryonic erythropoiesis—changing erythroid cell populations, changing haemoglobins and changing sites of erythropoiesis—was examined by several workers. J. Samarut *et al.* (Lyon) demonstrated the existence of separate erythroid stem cells specific for foetal and adult erythropoiesis respectively. Thus the situation contrasts with the synthesis of various immunoglobulin classes in B lymphocytes, which probably occurs in a single cell line (see Cooper below). J. Godet *et al.* (Lyon) identified membrane antigens specific for embryo and adult erythryocytes and A. Fantoni (Rome) showed that erythroid cells undergoing terminal differentiation in the 10–14-d mouse embryo synthesise haemoglobin by translating preformed long-lived messengers and that ageing leads to messengers which are unsuitable for terminating translation, thus resulting in reduced haemoglobin synthesis. The role of long-lived messengers in erythropoiesis leads one to wonder whether they may not operate in lymphopoiesis—perhaps explaining how a single lymphocyte can express two immunoglobulin classes at the same time. R. A. Rifkind (New York) discussed the regulation of foetal erythropoiesis. While erythropoietin serves as a cell-specific growth regulator (? at a proerythroblast stage), the rate of terminal differentiation is controlled at a more distal step along the erythroid pathway. In addition, changes in the composition of erythroid chromatin proteins probably have an important regulatory role (V. M. Ingram, Massachussetts Institute of Technology). R. Jacquot (Reims) and O. Gallien-Lartigue (Orsay) described new observations on the effects of glucocorticoids on foetal erythropoiesis.

The ontogeny of the immune response with its important implications for the generation of diversity of responsiveness was discussed next. L. Du Pasquier (Basel) pointed out that a broad range of antibody diversity appears early in amphibian development when the animals possess a small number of lymphocytes. This interesting observation is somewhat surprising in view of the restricted responsiveness of individual lymphocytes to antigen as envisaged by clonal selection and established by experiment. M. Cooper (University of Alabama, Birmingham) and P. Kincade (New York) showed that heterogeneity of responsiveness in terms of specificity and class of antibody is generated in the avian bursa of Fabricius from day 12 of incubation. Evidence that various immunoglobulin classes are generated within a single cell line by a preprogrammed switch mechanism in the bursa is convincing. On the basis of antigen binding studies, Cooper also suggested that specific clones of antigen-binding cells develop in a fixed sequential pattern which is not influenced by exogenous antigen. He interpreted this data as favouring a model in which individual stem cells give rise to multiple clones of B lymphocytes by a predetermined pattern of sequential expression of V-region genes. P. Toivanen (Turku, Finland) also pointed to the importance of the bursa which he showed was an important source of cells able to reconstitute immunodeficient chicks.

The importance of a circulating thymic factor (TF) in T-cell differentiation was discussed by J. F. Bach (Paris). This factor has been shown to possess several biological activities including restoration of suppressor and cytotoxic T-function in thymus-deprived mice. Its effect may be mediated by prostaglandins as well as cyclic AMP (M. A. Bach, Paris). TF seems to be one of the most functionally active factors of the various putative thymic hormones that have been described and so its further study is of considerable interest; however, the target cell for the action of these factors is as yet unclear and F. Loor (Basel) described studies with nude mice which suggested that T-cell differentiation begins at a prethymic level. Le Douarin *et al.*, however, presented evidence that stem cells which have already settled in the bursa can migrate to and differentiate in the thymus. Does this mean that stem cells which would have become B lymphocytes can instead become T cells if they are in the thymic microenvironment? Whatever the answer to these problems it is likely that various differentiation pathways are involved in the generation of T-cell subsets which were described in the thymus by M. Papiernik (Paris) and in the periphery by P. Häyry (Helsinki). Moreover, to obtain full functional maturation as described by R. Auerbach (University of Wisconsin, Madison), it seems likely that cell proliferation will be a crucial step as has been found in erythroid maturation by Rifkind.

In summary, the meeting was important in defining somewhat neglected areas for future study. In particular, most participants found the interdisciplinary approach of considerable value. □

A hundred years ago

Mr. Cross on Monday received a very numerous deputation from the British Medical Association, who laid before him their views with regard to the Vivisection Bill now before Parliament. These opinions were conveyed by Mr. Ernest Hart, Mr John Simon, Dr Wilks, senior physician of Guy's Hospital, and Sir W. Jenner, who raised his voice against a measure which would place men of science under police supervision, and would lay a ban upon them for inflicting cruelties on the lower animals when ten thousand times greater cruelties were inflicted by those who were going to pass this Bill. Such conduct would make those who passed it objects of scorn to all the scientific men in Europe. The Home Secretary, in reply, pointed out that the Bill was framed practically in accordance with the views of the Royal Commission, and that whether the Bill passed now depended entirely upon the line of conduct pursued by the medical profession.

R. G. Strom
Radiosterrenwacht, Dwingeloo, Netherlands

A. G. Willis
Sterrewacht, Leiden, Netherlands

A giant radio source with an unusual Z-shaped structure extending over nearly one degree on the sky has been detected around the nearby elliptical galaxy NGC315. The source has structure aligned with the minor axis of the optical galaxy on linear scales ranging from a few tens of kpc to ~ 1.7 Mpc. There is also a bright compact (<48 pc) source with an opaque radio spectrum located in the galactic nucleus. The physical properties of the extended emission are compared with those of the other three well studied giant radio galaxies—DA240, 3C236 and Centaurus A. The configurations of the giant systems with respect to their parent galaxies suggest that they are not produced by a gravitational slingshot process. The unusual morphology of the source is readily explained in terms of the rotating-beam model of Henriksen and Bridle.

WE report new radio observations of the bright (m_{pg}= 12.5 mag) elliptical galaxy NGC315 which reveal emission close to the minor axis of the galaxy over nearly 1° on the sky. This evidence suggests that it is a giant radio source some 1.7 Mpc in extent, at a distance of 100 Mpc. Only 3C236 has a linear size substantially larger than this.

Radio emission from NGC315 was first detected by Davis[1] in a 1.4-GHz survey where it was catalogued as DW0055+30. In the BDFL catalogue[2] of intense sources at 1.4 GHz it was included in the set of "confused fields", which have high probabilities of being multiple sources of large angular extent. Recently, Fanti *et al*[3] have presented a detailed study of the central radio source. We have mapped approximately one square degree around NGC315 at high sensitivity using the resurfaced Arecibo reflector at 2.38, 1.41 and 0.43 GHz and the Westerbork synthesis telescope at 0.61 GHz. The results confirm that NGC315 is associated with emission features at least 30′ and probably 1° in extent. High resolution maps of the central region have also been made with the NRAO 4-element interferometer at 2.7 and 8.1 GHz.

Radio structure of the source

Figure 1 shows contours of the emission around NGC315 observed at Arecibo with the system parameters listed in Table 1. The central source coincides with the visible galaxy and is joined by a bridge of emission to the peak of an extended feature ~16′ to the north-west in position angle −48°. The central source, the bridge and this north-preceding extended feature comprise the confused region

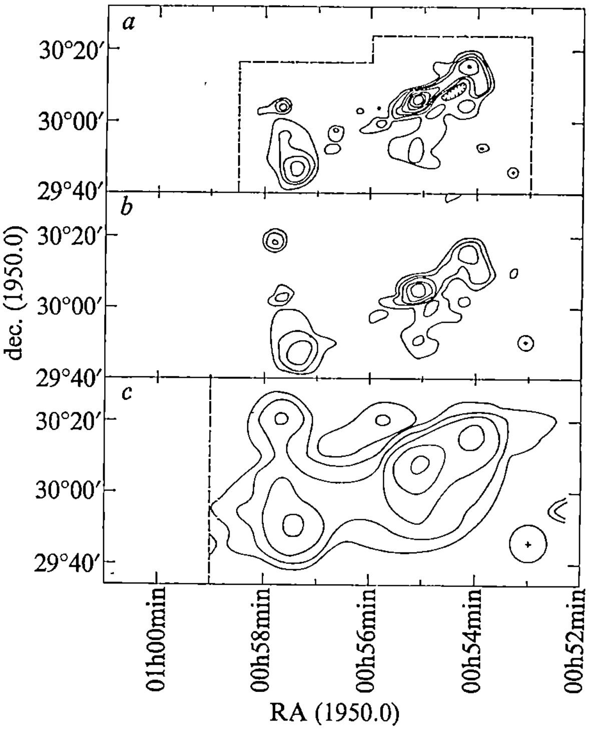

Fig. 1 Contours of the emission around NGC315 observed at Arecibo at three frequencies. *a*, 2.38 GHz, contours at 12.5, 25, 50, 100, 200, 400 and 800 mJy per beam. *b*, 1.41 GHz, contours at 50, 100, 200, 400, 800 mJy per beam. *c*, 0.43 GHz, contours at 125, 250, 500, 1,000, 2,000 mJy per beam. The dashed lines delimit the mapped regions and the half-power beamwidths are shown as the circles in the lower right corner of each map.

Table 1 Arecibo system parameters

Frequency (GHz)	Beamwidth (arc min)	System temperature (K)	Bandwidth (MHz)
2.38	3.0	42	20
1.41	4.0	120	10
0.43	10.0	120	2

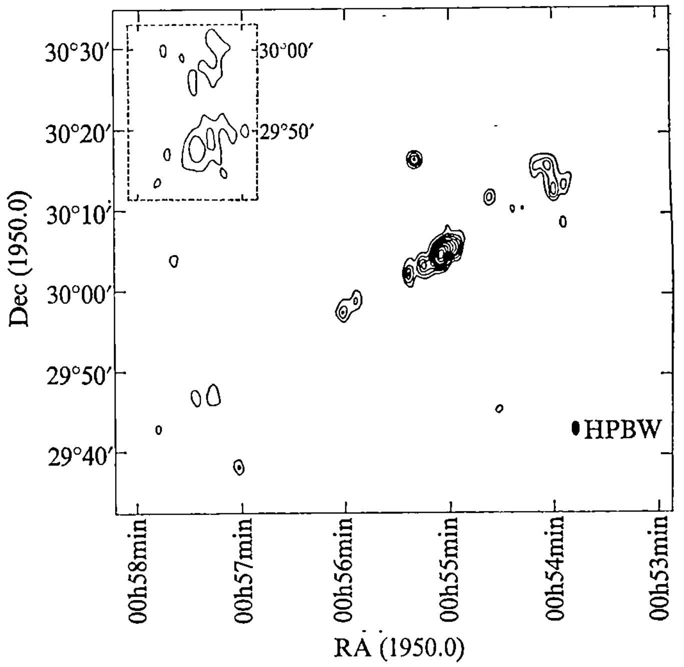

Fig. 2 Contours of the 0.61-GHz emission around NGC315 observed at Westerbork with 1′ (α) × 2′ (δ) resolution. Contours at 25, 50, 75, 100, 150, 200, 300, 400, 500, 750 and 1,000 mJy per beam. The insert, displaced in declination only and with the same contour values, shows the south-eastern lobe when convolved to a resolution of 2′ (α) × 4′ (δ). The maps have not been corrected for attenuation by the 1.4° primary beam.

noted by BDFL. The continuity of the radio emission from the galaxy to the extended feature leaves little doubt that all of this emission is related to NGC315. The 2.38-GHz map also clearly shows a spur of emission extending for >15′ SE of NGC315 towards the peak of a second emission feature located at 35′ from the galaxy in position angle 122°. This 'spur' is also visible, though less well defined, on the 1.4-GHz map; its alignment with the south-following feature suggests that the entire emission complex is associated with NGC315.

It is unlikely that the region is confused by foreground galactic features since the galactic latitude of the source is −32°. The probability of finding two unrelated extended features of this intensity aligned with 'bridge' and 'spur' protruding in nearly opposite directions from NGC315 is also very small. Inspection of the Palomar sky survey prints of the field shows that no other galaxies of brightness comparable to NGC315 are located within the extended radio features. The 14.1-mag galaxy NGC311 at 00 h 54 min 49.6 s, +30° 00′ 35″ (L. L. Dressel and J. J. Condon, unpublished) lies near the weak emission ~6′ from NGC315 in position angle ~220°, so this emission may not be related to NGC315. With this exception it is very probable that the entire extended structure shown in Fig. 1 is a single radio galaxy of exceptional angular extent.

The Westerbork telescope works at a frequency of 0.61 GHz, a synthesised beamwidth of 1′×2′, a system temperature of 350 K, a bandwidth of 4 MHz, a shortest baseline of 54 m, with increments of 72 m up to 1,422 m and an average HA of cuts of −76°, −35°, −1°, +37° and +77°. Observations consist of 12-min measurements made at five different hour angles. The resulting synthesised beam has radial grating responses which have been removed from the map by the usual CLEAN[4] procedure. The map in Fig. 2 shows a strong unresolved central component with a near-in extension of 2′ directed north-west and a longer but less intense counter component pointing south-east. Further to the south-east (near 00 h 56 min, +29° 58′) a small feature appears which is also well aligned with the major axis of the extended central emission. A ridge in the north-preceding component running nearly transverse to the source major axis is apparent. The south-following component, though heavily resolved, becomes clearly visible when the data are convolved to a 2′×4′ beam. Considering their different resolution and sensitivity, the Westerbork and Arecibo maps are in excellent agreement.

Figure 3 shows structure on a scale of ~90″ detected at 2.7 GHz near the unresolved nuclear source, which has been subtracted from this map for clarity. This structure is elongated along the position angle 133±3°, and is ten times brighter north-preceding the nucleus of NGC315 than on the south-following side at this resolution. In spite of the change in frequency, the structure seems similar to that shown in the 1.4-GHz map[3]. The emission, whose linear scale is ~50 kpc, comparable with that of some ordinary radio galaxies, comprises the most intense parts of the bridge and spur detected in the measurements at Arecibo and Westerbork. It also lies within NGC315, which has a diameter of 65 kpc and whose projected minor axis of 132±4° is close to that of the radio axis from ~50 kpc to 1.7 Mpc.

Comparison with other giant radio galaxies

Table 2 summarises the physical parameters of NGC315 using $z=0.0167$ (ref. 5) with the Hubble constant taken as 50 km s^{-1} Mpc^{-1}. The separation of the components places this radio source in the class of giant radio galaxies such as DA240, 3C236 and Centaurus A. Physical parameters[6] for these other sources are also given in Table 2.

As in the other giant sources, NGC315 contains a compact radio component located within the visible galaxy. An unresolved (<0.1″) source with an opaque spectrum

Table 2 Parameters of extended components of giant sources

	NGC315		DA240	3C236	Cen A
	North-preceding	South-following	Average	Average	Average
α(1950.0)	00 h 54 min 11±1 s	00 h 57 min 21±1 s	—	—	—
δ(1950.0)	30° 15′30″±1′	29° 46′ 10″±1′	—	—	—
Flux density (2.38 GHz)	0.55	0.45			
Projected distance from galaxy (kpc)	450	980	600	2,700	400
Volume (kpc^3)	1.3×10^6	2.2×10^6	2.7×10^8	1.3×10^9	9.9×10^7
Spectral index α	−0.52	−0.53	−0.77	−0.60	−0.6
Luminosity (W) 10 MHz–10 GHz	6.4×10^{33}	5.2×10^{33}	1.3×10^{35}	4×10^{35}	8×10^{34}
Minimum internal energy (J)*	6.0×10^{50}	6.7×10^{50}	1.4×10^{52}	5.4×10^{52}	9×10^{51}
Equipartition magnetic field* (gauss)	1.3×10^{-6}	1.1×10^{-6}	1.5×10^{-6}	1.2×10^{-6}	1.0×10^{-6}

*Assuming equal energies in protons and electrons, and that the source volume is uniformly filled.

coincides with the nucleus of NGC315 to within the ~3″ uncertainty in the optical position (ref. 3, and L. L. Dressel and J. J. Condon, unpublished).

The physical parameters of this nuclear source are given in Table 3. We can compare the 2.7-GHz and 8.1-GHz flux densities of the nuclear source with the values tabulated in ref. 3. This shows that the spectrum flattens out between 5 GHz and 8.1 GHz, if the source has not varied.

As in the other giant radio galaxies, the outer components of NGC315 are substantially extended transverse to their axis of separation from the optical galaxy. The NRAO interferometer observations show that neither peak in the outer components contains structure <5″ in extent stronger than 20 mJy at 2.7 GHz, and the Westerbork observations show there are no features <1′ stronger than 60 mJy at 0.61 GHz in the south-following component. The faint extensions of the outer components show an unusual symmetry with respect to the galaxy. The more distant, south-following component subtends the same angle (~40°) at the galaxy as does the closer, north-preceding component. The outer isophotes of both components are extended almost at right angles to the line joining their peaks, but in opposite directions. As the emission bridge and spur point towards these peaks, the overall form of the structure is best described as a Z shape whose extremities are equal arcs centred on the galaxy.

The extended features of the source seem to have a spectral index $\alpha=-0.5\pm0.2$ with little variation across the entire source except for the nuclear component. There is some indication from the 0.43-GHz map that the northwards extension of the south-following component may have a steeper spectrum than the rest of the source, but the present data do not allow us to place firm constraints on spectral index variations with size scales $\lesssim 5'$.

Discussion

As in the giant system 3C236 (refs 6, 7 and 8) the radio emission is elongated along the projected minor axis of the optical galaxy both far from NGC315 and near its nucleus. This is at variance with the gravitational 'slingshot' model of source formation[9] unless we make the unconventional assumption that NGC315 and 3C236 are both prolate rotators, so that their minor axis lies in their rotational equators Even then the observed alignments of their inner and outer radio structure would be statistically implausible. As the rotation axis of the giant source Cen A is known to lie near the overall elongation of both its large and small scale radio structure[10], the orientations of giant radio sources relative to their galaxies seem generally to conflict with a slingshot model for their origin. This contrasts with the orientations of double radio galaxies of 'normal' dimensions, which show no strong preference for galactic minor axes[11,12].

Fig. 3 Contours of the 2.7-GHz emission near the nucleus of NGC315 observed with the NRAO interferometer, after subtraction of the bright nuclear component (see Table 3) at the position marked by the cross The contour interval is 12 mJy/beam. The ellipse in the lower right corner indicates the half-power beamwidths, which are 11.4″ × 4.9″ with the major axis along position angle 138°. The dotted ellipse indicates the extent of the visible galaxy on the E print of the Palomar Sky Survey

Minimum internal energy*	1.5×10^{46} J
Equipartition magnetic field*	$>10^{-3}$ gauss

*With assumptions as in Table 2.

The unusual Z-like configuration and rotational symmetry of the outer components with respect to NGC315 suggest that the development of a classical 'double' structure has been modified either by a mechanism acting on the components outside the galaxy or by a perturbation of the primary collimation mechanism producing the double structure. The source morphology could, for example, be produced by diffusion of particles and fields governed by asymmetries in the environments of the components such that material near the peak of the northern component can diffuse more readily towards the south, and vice versa. The fact that both components subtend the same angle at NGC315 would, however, require a specially contrived slab-like symmetry in the environment, extending over nearly 2 Mpc near the galaxy. Unless we regard the symmetrical appearance of the source as fortuitous, it is more attractive to consider an interpretation in which the primary source-collimating mechanism appears to have rotated on the sky during the lifetime of the radiating particles.

Such a rotation is implicit in the model of extended sources recently advanced by Henriksen and Bridle (to be published), in which relativistic particles are beamed from radio galaxies into double-source components along magnetic flux ropes which are rigidly coupled to the rotation of the central regions of the galaxies. In their model, the outer source components are produced where the rigidity of the rotating beams fails because their rotational velocity approaches that of light. The Z-shaped morphology of the NGC315 source can be understood on the Henriksen–Bridle model if the relativistic beams make an angle of ~20° with the rotation axis of the central region of NGC315, and the rotation rate of this region and thus of the beams is $\sim10^{-14}$ s^{-1}. The outer extensions of the source components would then be explained as trails of particles and magnetic field left behind around the orbits of the beam ends over $\sim10^{7}$ yr. As ejection of the beams near the galactic rotation axes favours the formation of giant sources, the orientational correlation observed for radio galaxies of different linear sizes is also consistent with this model. A detailed discussion of NGC315 in relation to the rotating-beam model will be given elsewhere (Henriksen and Bridle, in preparation).

It should be noted that this giant source has been recognised by the same observational procedure as were DA240 and 3C236, namely sensitive mapping of a confused field from the BDFL catalogue at resolutions of the order of a few arc min. As the BDFL confused fields are an essentially complete sample of such regions at 1.4 GHz, it is unlikely that radio galaxies of large angular size comprise $>5\%$ of extragalactic sources stronger than 2 Jy at 1.4 GHz, and possibly comprise substantially less than this. Although they are valuable testing grounds for theories of radio galaxies, the giant systems probably do not represent a numerically important source population that is absent from catalogues such as that of BDFL.

We thank Dr G. W. Brandie for assistance with the NRAO observations. This work was partially supported by the NRC of Canada The NRAO is operated by Associated Universities, Inc. under contract with the NSF The Westerbork Synthesis Radio Telescope is operated by the Netherlands Foundation for Radio Astronomy with financial support from the Netherlands Organisation for the Advancement of Pure Research.

Repeated sequence specific to human males

Howard Cooke

MRC Mammalian Genome Unit, University of Edinburgh, West Mains Road, Edinburgh EH9 3JT, UK

Restriction enzyme analysis and nucleic acid hybridisation show that there is a repeated sequence in human male DNA which is not present in human female DNA. This sequence is shown to constitute about 50% of the DNA in the Y chromosome and is a simple tandemly repeated DNA.

THE contribution of DNA sequence organisation to chromosome structure and function has been the subject of much speculation[1-3], but there is still very little concrete evidence to relate to the theories As a starting point, it is useful to know the location of specific sequences within the chromosomes. The technique of *in situ* or cytological hybridisation has been applied successfully to repetitive sequences such as satellite DNA, ribosomal DNA, 5S DNA and other sequences of this type[4-6]. The method is especially powerful when applied to polytene chromosomes where even single copy genes can be located One limitation of the method is that it is designed to locate sequences which can be purified as either RNA or DNA. Different methods are needed if the aim is to analyse the composition of a particular chromosome. For this it would seem necessary to isolate the chromosome It is difficult to purify individual chromosomes at present, but they can in many cases be separated from the rest of the complement by the formation of heterokaryons[7]. Comparative methods can then be used to analyse the sequences on the odd chromosome.

A comparable situation exists when one sex has a heterogametic sex chromosome In principle this chromosome can be studied by comparison of male and female. The experiments reported here use this approach to study the DNA of the human Y chromosome

Repeated sequence specific to the Y chromosome

When human DNA is digested with a number of restriction enzymes and the products analysed by electrophoresis on Agarose gels, two enzymes, *Eco*RI and *Hae*III[8,9], produce prominent bands. The sizes of the *Eco*RI bands are 320 and 640 base pairs[10] The band pattern with *Hae*III is more complicated, with at least fifteen bands between 100 and 2,000 base pairs (Fig. 1). A comparison of male and female human DNAs after digestion with *Hae*III showed that there are two bands which are found only in DNA from males. As a check DNAs from 12 individual placentae were sexed by restriction in a blind test. The correct sex was predicted from electrophoresis of *Hae*III digests of the DNA in all 12 cases.

The fraction of the total DNA in the male specific bands was estimated by adding known amounts of linear SV40 DNA to total human DNA which had been digested with *Hae*III (*Eco*RI digestion of SV40 closed circular DNA was used to produce linear SV40 DNA molecules[11]). The areas in the male specific bands and in the SV40 bands were compared by microdensitometry of photographs of ethidium bromide fluorescence[12]. The peak area of the SV40 band was proportional to the amount of this DNA added to the total human DNA. By this method the larger male specific band was estimated to be 0 4±0.1% (ten measurements) of the total DNA in both a placental male DNA and DNA from a male derived neuroblastoma cell line. In an identical experiment DNA from a lymphoid XYY line was found to have a large male specific band which was 0.75±0.1% (five measurements) of the total DNA.

The smaller of the male specific bands is more difficult to quantify because of the higher background of other DNA sequences at this molecular weight, it constitutes about 0.2% and 0.4% of the total DNA respectively. The lymphoid XYY cell line used here has a karyotype which is near normal apart from the presence of two large chromosomes which fluoresce brightly when stained with quinacrine Doubling the number of Y chromosomes doubles the proportion of the total DNA present in both the large and the small male specific bands, and this strongly implies that the sequence is present on the Y chromosome itself.

Differences have been found in the amount of Y chromosome fluorescence but no significant differences in the amount of the male specific bands could be detected between male DNA samples from six different placentae and four cell lines The method is, however, not sensitive enough to detect small differences.

Fragment lengths were measured by gel electrophoresis on slab gels with marker DNAs in adjacent slots λ.cDNA restricted with *Eco*RI was used as a standard for the larger bands[13] and *Eco*RII digested mouse satellite DNA for the smaller bands[14] Band sizes are given in Fig. 1. The larger of the male specific bands is not separable from the smallest λ.*Eco*RI band when the two DNAs are analysed on the same gel slot Its molecular weight is 2.24×10^6, the smaller of the male specific bands has a molecular weight of 1.6×10^6.

The human diploid nucleus contains 3.5×10^{12} daltons of DNA[15]. From these values, from the fraction of the DNA present in each of the two male specific bands and from

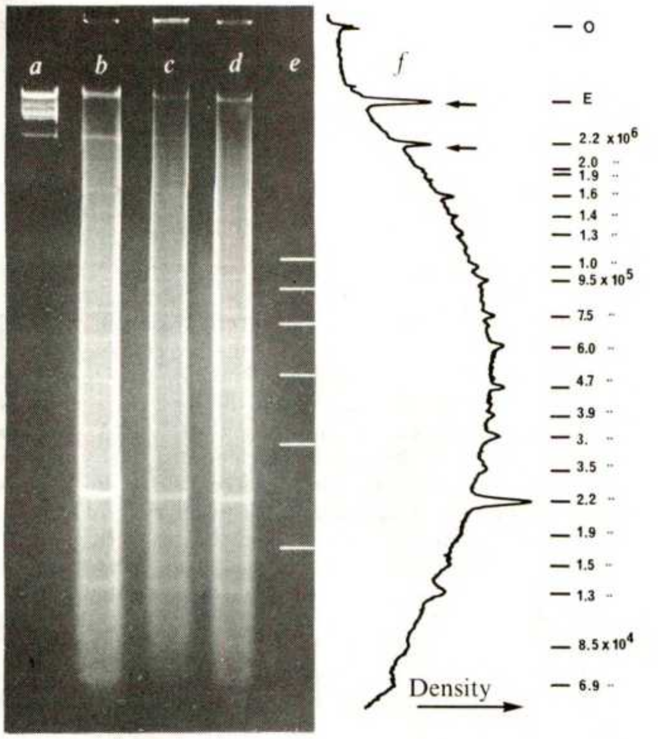

Fig. 1 DNAs restricted with different restriction enzymes after electrophoresis on a 2.5% Agarose slab gel. The gel was made up and run in 15 mM Tris, 18 mM NaH_2PO_4, 0.5 mM EDTA (*p*H 7.8) with a voltage gradient of 7 V cm^{-1} for 4 h. *a*, 0.2 microgrammes of λ.cDNA digested to completion with *Eco*RI in 10 mM NaCl, 10 mM MgCl, 10 mM 2-mercaptoethanol; the DNA was heated to 70 °C for 10 min after digestion to melt the sticky ends of the phage DNA. *b*, 10 µg of DNA from GIL cultured cells (this is a lymphoid cell line with two Y chromosomes—a gift from M. Steel). This DNA was digested to completion with *Hae*III in the buffer as in *a*. *c*, 10 µg of DNA from a male placenta digested with *Hae*III as in *b*. *d*, 10 µg of DNA from a female placenta digested as in *b* and *c*. *e*, 0.01 µg of mouse satellite DNA partially digested with *Endo*R *Eco*RII; the mouse satellite bands in this track were too faint to reproduce and so their positions were blocked in for this photograph. *f*, a trace of the pattern shown in slot *b* and reproduced at the same scale; the male specific bands are indicated by arrows and sizes in daltons of the principal bands given in the right hand column. O, origin of electrophoresis; E unresolved DNA.

their repeat length the number of copies of the sequences can be calculated as 6.2×10^3 for the large band, and 4.4×10^3 for the smaller band.

Restriction of fractions from a Ag–Cs_2SO_4 gradient followed by gel electrophoresis showed a considerable enrichment for the larger of the male specific bands on the light side of the main band DNA (Fig. 2). The smaller of the bands was not enriched in these fractions showing that the two bands arise from different repeated sequences. This is the region of the gradients which would be expected to contain human satellites III and IV[16].

Other restriction enzymes

Fractions from Ag–Cs_2SO_4 gradients which were enriched for the large male specific band were recycled on identical gradients to give further purification. This DNA was digested with a number of restriction endonucleases to attempt to map restriction sites within the *Hae*III repeat length. Seven other restriction enzymes were available, *Eco*RI, *Eco*RII, *Hae*I, *Hae*II, *Hin*dIII, *Hpa*II and *Bam*I[17]; of these only *Eco*RI gave a distinct band. This had the same mobility as the larger *Hae*III band, but had about one third the intensity. Double digestions with *Hae*III and the enzymes listed above confirmed that the *Hae*III repeat did not contain any of these restriction sites at a frequency high enough to give visible bands. The result with *Eco*RI suggests, however, that a subset of the repeated sequence contains *Eco*RI sites at the same spacing as the *Hae*III sites. At present it is not possible to say whether the two sites are on the same or separate molecules.

The resistance of this DNA fraction to such a wide range of restriction enzymes is to be expected since it is shown by sequence analysis described below to consist of a short repeat.

Isolation

As the 2.24×10^6-dalton fragment is not cleaved by a large number of restriction endonucleases, restriction with these enzymes can be used to remove most other sequences from the fragment partially purified by sizing. Human male DNA digested by *Hae*III was fractionated on a preparative gel electrophoresis apparatus (E. M. Southern, unpublished) and the DNA in the size class from 2 to 2.5×10^6 daltons taken, purified by CsCl centrifugation and concentrated. This DNA was then digested with *Hin*dIII, *Bam*I and *Eco*RII and fractionated on an Agarose slab gel. The male specific band was 70 to 80% pure as judged by microdensitometry of the gel photographs. The band was cut from the gel and the DNA recovered on to hydroxyapatite[12]. Male specific DNA was isolated in this way rather than by Ag–Cs_2SO_4 centrifugation because larger quantities of DNA could be used; the method is also faster and less expensive than centrifugation in Cs_2SO_4.

Homology with other sequences in male and female human DNA

It is clearly of interest to see whether the large male specific band has any sequence homology with other fractions both

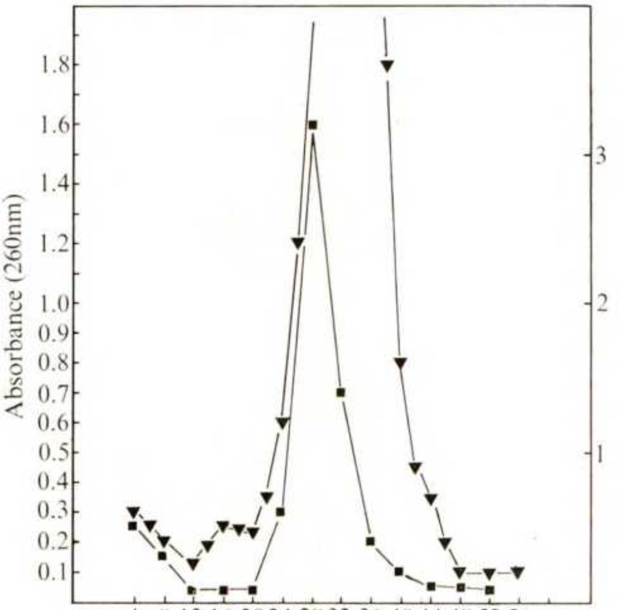

Fig. 2 Preparative Ag^{2+}–$CsSO_4$ centrifugation of human male DNA from placenta was carried out essentially as in ref. 21. Human male DNA was dialysed exhaustively against 0.1 M Na_2SO_4. Gradients were made up in 5 mM $Na_2B_4O_7$ (*p*H 9.3), 0.1 M Na_2SO_4, the silver to DNA phosphate ratio was adjusted to 0.2 and the final density of the solution to 1.48 g ml^{-1}. Centrifugation was carried out in a MSE 8 × 40 rotor at 32,000 r.p.m. for 4 d. The gradients were fractioned with a float from the top and groups of four fractions were pooled, dialysed against 4 M NaCl and the DNA concentrated by pelleting at 30,000 r.p.m. in a MSE 10 × 10 rotor overnight. Each set of pooled fractions was then restricted with *Hae*III and the products analysed by Agarose gel electrophoresis. The pattern in each slot was traced on a Joyce–Loebl recording microdensitometer and the percentage of the total area under the curve present in the male specific band calculated for each fraction: ▲, absorbance at 260 nm; ■, percentage of total DNA present in the male specific band.

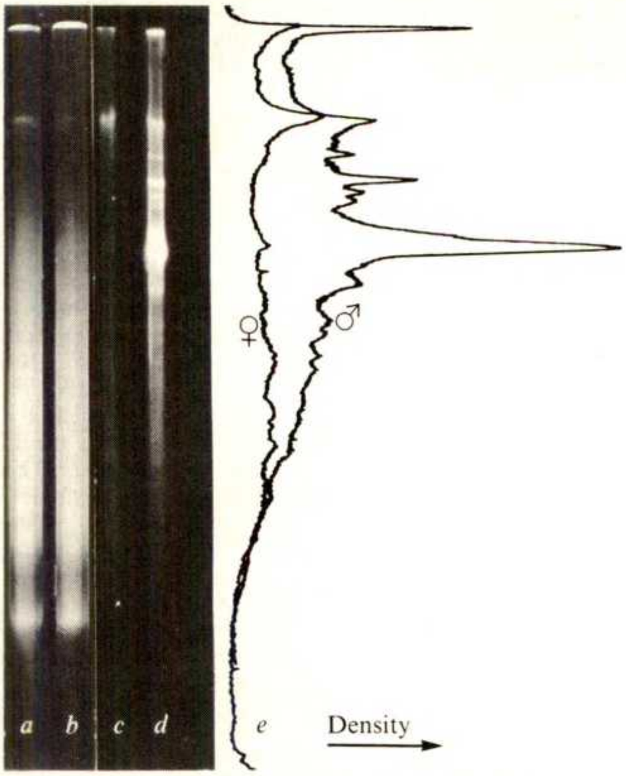

Fig. 3 Hybridisation of cRNA from the male specific band to male and female DNA. 80 μg of human male and female DNAs were digested to completion with *Hae*III then the fragments fractionated by electrophoresis on 0.8% Agarose tube gels, 1.0 cm diameter × 25 cm with a voltage gradient of 1 V cm^{-1} for 6 h. After electrophoresis the gel was photographed and the DNA fragments transferred to membrane filters as in ref. 20. Male and female DNAs were transferred simultaneously to one sheet of Millipore filter and this sheet of filter immersed for 18 h at 60 °C in a small volume (about 5–10 ml) of 2×SSC containing 0.01 microgrammes of ^{32}P-labelled cRNA with a specific activity of 2×10^8 d.p.m. μg^{-1}. After hybridisation and washing the filter was dried and autoradiographed. *a*, Gel containing female DNA before transfer to filter; *b*, gel containing male DNA before transfer to filter; *c*, negative of autoradiograph of hybridisation to female DNA; *d*, negative of autoradiograph of hybridisation to male DNA; *e*, microdensitometer trace of autoradiographs in *c* and *d*. *a*, *b*, *c*, *d*, and *e* are all reproduced on the same scale.

in male and female DNA. If, as has been suggested, tandemly-repeated sequences are involved in the meiotic pairing of chromosomes[18] it would seem unlikely that sequences related to the Y specific sequence will be found elsewhere.

Absence of an homologous band in the restriction pattern is not sufficient to rule out the possibility that female DNA contains a similar sequence. First, the method would not detect less than 1,000 copies and second, bearing in mind what is known about the evolution of repeated sequences[12,14,19], it is possible for related sequences to give completely different restriction patterns. A more sensitive and general test for sequence homology is given by molecular hybridisation and this method is especially convincing when applied to restriction fragments separated by gel electrophoresis[20].

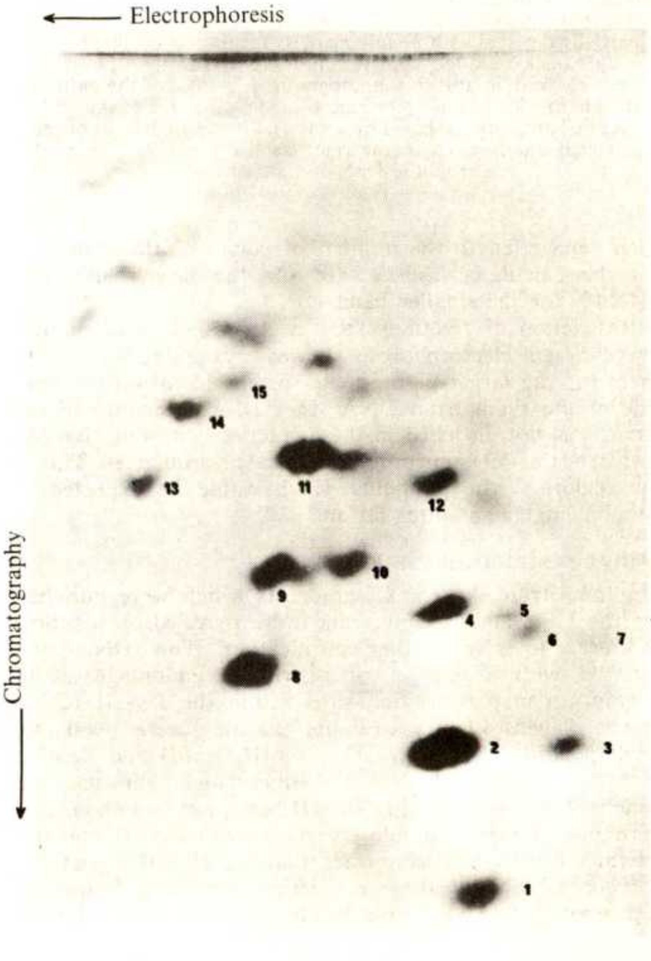
An RNA copy of the 2.2×10^6-dalton fragment labelled with ^{32}P was synthesised using *E. coli* RNA polymerase. As judged by microdensitometry this fragment was 70% pure. *Hae*III fragments of male and female human DNA were separated on Agarose gels, denatured and transferred to strips of cellulose nitrate filter. The cRNA was then hybridised to the DNA bound to the cellulose and the strip was autoradiographed using X-ray film. The results of such an experiment are shown in Fig. 3.

As expected, male DNA gives a very intense band of hybrid at the position corresponding to 2.2×10^6 daltons, with weaker bands at positions corresponding to 4.5 and 6.7×10^6 daltons, the predicted sizes for dimer and trimer of the 2.2×10^6 dalton fragment. In addition, there are two bands between 2.2 and 4.5×10^6 daltons, and a number of indistinct bands smaller than 2.2×10^6 daltons. The male specific band which can be seen in *Hae*III restricted DNA at 1.6×10^6 daltons does not hybridise the cRNA probe used here and so is not closely related to the larger male specific sequence, in agreement with the behaviour in density gradients.

In contrast, female DNA gives a much weaker and different pattern. It shows one weak band at the position of DNA which is not cleaved by the restriction enzyme and a very faint band at the position of the larger male specific sequence. The latter is almost certainly due to sequences in the cRNA which originate from this size class of DNA and are not removed in purification of the Y specific sequence. The hybridisation to undegraded DNA occurs in both male and female and could be caused by a cross reaction to a related sequence present in both male and female DNA which does not contain the restriction site.

These results suggest that in human male DNA there is a complex family of repeated sequences related to the 2.2×10^6-dalton DNA fragment. This complexity most probably reflects the structure of the sequences on the Y chromosome since they are not present in female DNA. The presence of dimers and trimers of the 2.2×10^6-dalton sequence suggests that divergence is taking place in a tandemly-repeated sequence in a similar way to the *Mus musculus* and *Apodemus* satellites[12,14].

Fig. 4 Autoradiograph of RNase T_1 digest of ^{32}P labelled cRNA complementary to the male specific band. The cRNA was synthesised as in ref. 21 using ^{32}P-labelled GTP with a specific activity of 2 Ci mmol^{-1}. Electrophoresis and chromatography was carried out as in ref. 21, followed by chromatography on polyethylene-imine cellulose thin layers.



Fingerprint analysis

Figure 4 shows a ribonuclease T_1 fingerprint of cRNA transcribed from the large male specific band using ^{32}P-labelled GTP[21]. There are a number of intense spots which fall mostly in the short sequence region of the fingerprint with very small amounts of radioactive oligonucleotides present in the position of the longer sequences. The more intense spots (numbered in Fig. 4) were cut from the fingerprint and subjected to sequence analysis by pancreatic ribonuclease digestion. Table 1 gives the sequences of the spots from the ribonuclease T_1 fingerprint and the percentage of total counts in the excised spots for each sequence. Sixty-seven per cent of the total activity counted was in three sequences, AG, UG, and A_2 UGG; many of the sequences present in smaller amount could be accounted for by base substitution into these sequences. Although it is not possible to derive a definitive sequence from this data it is clear that the sequence is a simple one which has diverged from a repeating oligonucleotide such as $(AGUGG)_n$. This is the pattern of divergence which has been found in a number of satellite DNAs[22,23].

Table 1 Sequences of spots from ribonuclease T_1 fingerprints

Spot no.	% Counts	Composition	Sequence
1	5.5	G	G
2	33.6	AG	AG
3	2.3	CG	CG
4	5.8	A_2G	AAG
5	0.58	ACG	ACG
6	1.32	ACG	CAG
7	0.25	C_2G	CCG
8	16.9	UG	UG
9	5.5	AUG	AUG
10	3.0	CUG	CUG
11	16.9	A_2UG	A_2UG
12	2.66	C_2UG or A_3G	A_3G
13	1.9	U_2G	U_2G
14	2.5	U_2AG	U_2AG
15	0.87	—	—

Spots on the fingerprint in Fig. 4 were located by autoradiography, cut from the thin layer and counted in toluene base scintillator. After counting, the oligonucleotides were eluted, digested with ribonuclease A and analysed by electrophoresis as in ref. 21.

Discussion

The human Y chromosome is about the same size as chromosomes 21 and 22, each of which contains about 0.82% of the absorbence of the diploid karyotype at 257 nm[24]. On the assumption that the Y chromosome contains a similar proportion of the total DNA the two male specific bands described here would account for 70% of the DNA in the Y chromosome. The mammalian Y chromosome has been considered to be largely genetically inactive on the basis of its heterochromatic appearance[25]. It must, however, have genetic activity since genes on the Y chromosome must switch development of the embryonic gonad towards production of a testis[26]. In addition there seems likely to be a gene, or a function of the testis-determining gene, responsible for production of the H–Y antigen in mammals[27,28]. These loci must either be pericentric or on the short arm of the Y chromosome in man since an isochromosome of the long arm of the Y chromosome does not cause testis formation[29].

At least some of the repeated sequences described above are likely to be on the long arms because of the correlation between repeated sequences and heterochromatin[30] or more simply because it is unlikely that the short arms could contain 70% of the Y chromosome DNA.

Four human satellite DNAs have been reported present on the Y chromosome but they are also found on a fairly large group of other chromosomes[31]. Clearly this is not the case for the sequence described here but neither the satellite DNAs nor this sequence have been sufficiently well characterised to rule out the possibility that this sequence is related to one or more of the human satellites. The lack of hybridisation to female DNA suggests that this sequence is not simply one of the satellite DNAs but the behaviour in Ag–Cs_2SO_4 density gradients suggests that it is possible that satellite I, III and IV could be contaminated with this sequence. This might explain some of the *in situ* hybridisation of these satellites to the Y chromosome.

The conclusion which is inescapable from the *in situ* hybridisation and the experiments reported here is that the human Y chromosome must contain very little apart from simple sequence DNA.

The functions of repeated and satellite DNAs remain unknown in spite of much work on the structure and organisation of this class of DNA sequences. There are two questions raised by the data reported here which have obvious significance in terms of repeated sequence function; why is there so much repeated sequence DNA on the Y chromosome and why is the sequence described here found only on the Y chromosome? One answer to the first question could be that since the male-determining genes must segregate during spermatogenesis they must be present on a chromosome. If these genes are coded by small amounts of DNA then perhaps it is necessary to add other DNA to produce a chromosome. The repetitive sequences may be such genetically neutral DNA.

A further consequence of the need to ensure that genes on the Y chromosome segregate is that no crossing-over with other chromosomes can be tolerated[32]. This requirement could provide the answer to the second question above if the presence of a set of sequences unique to the Y chromosome prevented chiasmata formation with other chromosomes. The X and Y chromosomes in man have a terminal association during diakinesis and first meiotic metaphase[33] which involves the short arms of both chromosomes[34,35] but which does not have the normal form of synaptenemal complex and at meiosis they form a special structure as in most mammals[36]. The Y specific sequences could either be involved in this behaviour or could be a result of it.

The genetic isolation of the Y chromosome might allow a unique set of repeated sequences to be produced either by saltation[22] or by sister chromatid exchanges[37]. The formation must have been fairly recent since DNA from male chimpanzees shows no homologous band in the restriction pattern with *Hae*III (K. W. Jones, personal communication). It is of course possible that related sequences without the restriction site are present.

The availability of RNA complementary to a human Y specific sequence should allow further study of the evolution and distribution of these sequences. Clearly this type of study can be extended to repeated sequences of other chromosomes by the use of DNA from mouse/human somatic cell hybrids which contain only a single human chromosome.

I thank E. M. Southern and P. M. B. Walker for many discussions of this work and for criticisms of the manuscript, and C. Gosden for her help with the blind test and in providing placentae. This work was supported by the MRC

Note added in proof: A human Y specific sequence has been purified by extensive hybridisation of male and female DNA (ref. 38). The authors found that there is a repeated sequence DNA which constitutes between 2 and 11% of the human Y chromosome. This sequence is most likely to be one of the sequences described here. The major difference between the results reported in this paper and in ref. 38 is in the amount of the Y specific sequence. Calculations of the amount of sequences by Kunkel *et al.*, are rather indirect and assume that all Y specific repeated sequences are recovered at each step of purification. Cumulative losses in the purification procedure could thus account for

an underestimate of the quality of Y specific repeated sequences present in the human genome.

Initiation sites of Rous sarcoma virus RNA-directed DNA synthesis *in vitro*

Linda M. Cashion, R. H. Joho, Margaret A. Planitz, M. A. Billeter & C. Weissmann

Institut für Molekularbiologie I, Universität Zürich, 8049 Zürich, Switzerland

Rous sarcoma virus DNA synthesis in disrupted virions is initiated mainly at a site about 200 nucleotides or less from the 5′ terminus, but other initiation sites throughout the RNA seem to be used as well. No AUG triplet occurs within a 5′ terminal segment of about 25 nucleotides.

THE RNA genome of avian oncornaviruses consists of two[1] identical RNA strands, each with a molecular weight of about 3×10^6 (about 10,000 nucleotides)[2-4]. During the early stages of the infective cycle the viral genome is transcribed into a complete double-stranded DNA copy of molecular weight 6×10^6 (ref. 5). When DNA is synthesised *in vitro*, however, in partially disrupted virus particles, the product is short, averaging only a few hundred nucleotides (see review by Green and Gerard[6]). Nonetheless, a small percentage of the DNA strands can reach a length of 1,500 to 4,500 nucleotides[7] or even the length of the viral RNA[8]. The short size of the bulk of the product is believed not to be due to nucleolytic scission of the DNA, since short DNA was also synthesised in reconstituted systems devoid of detectable nuclease activity[7,9]. A substantial fraction of the *in vitro* DNA product is complementary to a small region of the viral RNA[10,11], although sequences complementary to virtually all the viral RNA are present[10,12].

Several groups have reported that most or all DNA generated *in vitro* is attached to the 3′ end of a unique species of RNA primer[13,14] (tRNA^{Trp} in the case of Rous sarcoma virus RNA (ref. 15)) and that only one molecule of this primer is associated with each viral RNA subunit[16]. It therefore seemed reasonable to assume that DNA synthesis started close to the 3′ end of the RNA template and that premature chain termination gave rise to incomplete DNA strands with the properties described above. Recently, however, Taylor and Illmensee[16] reported that DNA transcription begins very close to the 5′ terminus of the RNA. This conclusion raised the question as to how sequences complementary to almost all the RNA are synthesised and how long DNA strands are generated.

We have examined the origin and the complexity of the DNA synthesised by disrupted Rous sarcoma virus, Prague B strain (Pr-B RSV), in the following way. The DNA was annealed with Pr-B RSV ^{32}P-RNA, and the hybridised RNA was characterised by digestion with RNase T_1 and identification of the resulting large oligonucleotides. The location on the viral RNA of the regions complementary to the cDNA could be determined from the physical map of large T_1 oligonucleotides of Pr-B RSV RNA established in our laboratory[17,18]. It was found that the most frequent DNA species corresponds to a region which is not more than 200 nucleotides in length and includes the 5′ terminus of the RNA. Several other non-contiguous regions of the viral RNA, notably one located in the middle of the molecule, were also represented in varying amounts. These findings suggest that the major initiation site is located near the 5′ terminus but that DNA synthesis may also originate at various other positions throughout the genome.

RSV ^{32}P-RNA complementary to RSV cDNA

DNA synthesised by partially disrupted Pr-B RSV particles in the presence of actinomycin D was purified and hybridised to Pr-B RSV ^{32}P-RNA. Hybridisations were carried out at two concentrations of DNA, the lower one to hybridise preferentially the more prevalent DNA species and the higher one to ascertain the overall complexity of the DNA. The preparations were treated with RNase T_1 and the RNase-resistant fractions were isolated by chromatography on Sephadex G-100. At the lower DNA concentration 4.7% of the RNA was hybridised and at the higher concentration 13.2%. A control which had been annealed to globin cDNA yielded 2.0% of the input radioactivity (mainly due to poly(A), see below) in the hybrid fraction. The same quantity of ^{3}H-labelled 70S Pr-B RSV RNA was then added to each sample as an internal standard to monitor the recovery of radioactivity throughout the subsequent analysis. The mixture was denatured and digested to completion with RNase T_1, and the products were separated by two-dimensional polyacrylamide gel electrophoresis.

A standard fingerprint pattern of 70S Pr-B RSV RNA is shown in Fig. 1*a*; the characteristic, large T_1 oligonucleotides which are numbered in the tracing (Fig. 1*a*′) have been characterised, and their relative order on the genome has been determined[17,18]. Figure 1*b* shows the oligonucleotides recovered after hybridisation at the lower DNA concentration: only two of the characteristic large T_1 oligonucleotides appeared as intense spots, namely T_{13} and to a lesser extent T_1. The identity of these oligonucleotides was ascertained from their pancreatic RNase digestion products (data not shown). Three further spots, T_{51}, T_{52} and T_{53}, were also prominent. These fragments

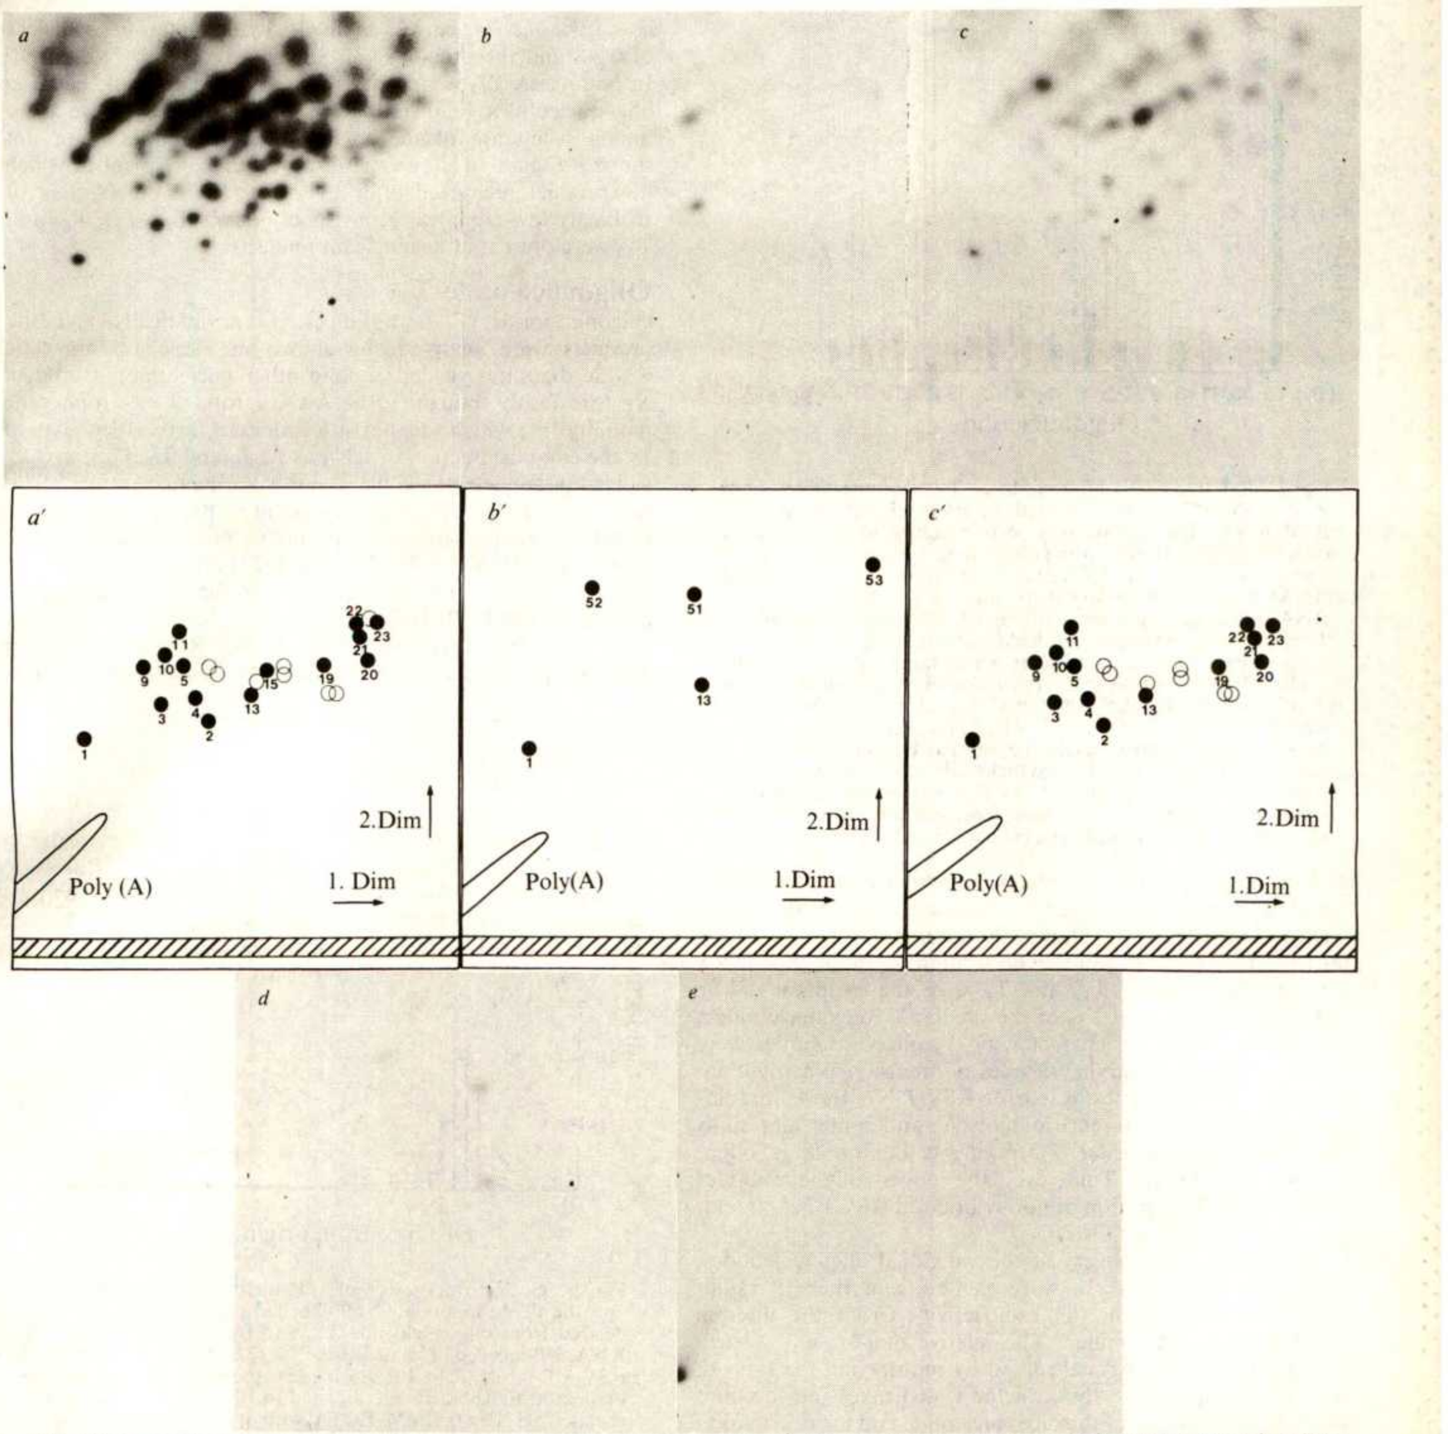

Fig. 1 Two-dimensional polyacrylamide gel electrophoresis of T_1 digests of Pr-B RSV ^{32}P-RNA recovered after hybridisation to different cDNA preparations. Rous sarcoma virus, Prague B strain (Pr-B RSV), was grown on chicken fibroblasts (Spafas, C/O, chf$^-$,obtained from R. Friis) as described[17], with the following modifications. Infected cells were passaged four or five times in Petri dishes and then seeded into Corning tissue culture roller flasks (490 cm^2, No. 25130) at a density of 3×10^7 cells per flask in 50–100 ml of Dulbecco's modified Eagle medium–10% Tryptone phosphate broth–5% calf serum. The virus was collected every 24 h and stored at −70 °C. Pr-B ^{32}P-RSV was prepared in roller bottles essentially as described[17]. Synthesis of Pr-B RSV DNA: Virus from 1 l of collected medium was concentrated by centrifugation for 60 min at 4 °C and 28,000 r.p.m. in the S30 Spinco rotor and suspended in 1 ml of 100 mM NaCl–50 mM Tris-HCl (*p*H 7.5)–1 mM EDTA. The concentrated virus suspension was incubated with 1 µl of β-mercaptoethanol and 0.3 ml of 1% NP 40 (w/v) for 5 min at 37 °C. The mixture was adjusted to 38 mM Tris-HCl (*p*H 8.0), 28 mM NaCl, 4.8 mM $MgCl_2$, 0.09 mM each dATP, dTTP, dCTP, and ^{32}P-dGTP (specific activity 3×10^3 c.p.m. nmol^{-1}), 24 µg ml^{-1} of actinomycin D (final volume, 2.1 ml) and incubated for 60 min at 37 °C. The preparation was then digested with 0.25 mg ml^{-1} of Pronase in the presence of 0.5% SDS for 15 min at 37 °C. After phenol extraction the combined aqueous phases were adjusted to 1% sodium acetate (*p*H 5) and precipitated with 2.5 vol of ethanol. After 2 h or longer at −20 °C, the precipitate was collected by centrifugation, redissolved in 250 µl of 50 mM NaCl–20 mM Tris-HCl (*p*H 8)–5 mM EDTA–0.1% sodium dodecylsulphate and chromatographed through a 0.6×8 cm column of Sephadex G-100 equilibrated with the same buffer. The excluded material was precipitated with ethanol, the precipitate dissolved in 100 µl of 0.2 M KOH, and digested for 16 h at 37 °C. The digest was neutralised and chromatographed through a 0.5×8 cm column of Sephadex G-100 in 20 mM Tris-HCl (*p*H 8)–0.1 M NaCl. The excluded material was precipitated with ethanol as above and dissolved in 20 mM Tris-HCl (*p*H 7.5)–5 mM EDTA. The yield in different preparations ranged from 0.3 to 1.5 nmol of incorporated dGMP. Analytical or preparative zonal centrifugation of the viral DNA was through a 4-ml 5–23% sucrose gradient in 50 mM Tris-HCl (*p*H 7.5)–0.2% SDS for 120 min at 55,000 r.p.m. and 15 °C in the SW60 Spinco rotor. A parallel tube was run with ^{125}I-labelled globin mRNA, Friend cell ribosomal ^{3}H-RNA and *E. coli* tRNA. Annealing reactions: 70S Pr-B RSV ^{32}P-RNA (specific activity > 10^6 c.p.m. µg^{-1}) was denatured in 20 mM Tris-HCl (*p*H 7.5)–5 mM EDTA for 1 min in a boiling water bath. Each annealing reaction mixture contained 2×10^6 c.p.m. of the denatured Pr-B RSV ^{32}P-RNA, DNA as indicated below, 0.5 M NaCl, 0.01 M Tris-HCl (*p*H 7.5) in 100 µl and was incubated for 4 h at 66 °C. The solution was diluted to 0.25 M NaCl (200 µl) and digestion carried out with 4 U of RNase T_1 (Calbiochem) for 30 min at 37 °C in the presence of 25 µg of yeast RNA (purified by phenol extraction). After phenol extraction the aqueous phase was chromatographed on a 1×16 cm column of Sephadex G-100 in 0.5 M NaCl–0.01 M Tris-HCl (*p*H 7.5). To the pooled excluded fractions were added Qβ RNA (100 µg) and 70S Pr-B RSV ^{3}H-RNA (2.5×10^5 c.p.m., specific activity > 10^6 c.p.m. µg^{-1}) as carrier and internal standard, respectively. The nucleic acids were precipitated twice with ethanol, taken up in 6 µl of 20 mM Tris-HCl (*p*H 7.5)–2 mM EDTA, sealed in a capillary, heated for 1 min in a boiling water bath and chilled. The RNA was digested with 16 U of RNase T_1 in 10 µl of the same Tris-EDTA buffer for 30 min at 39 °C. The products were subjected to two-dimensional polyacrylamide gel electrophoresis as described[17]. The autoradiograms are of the following samples: *a*, Total T_1 digest of untreated Pr-B RSV ^{32}P-RNA, directly subjected to two-dimensional polyacrylamide gel electrophoresis; *b–e*, were processed as described above; the DNA in the annealing mixtures was as follows: *b*, Pr-B RSV DNA, equivalent to 120 pmol of dGMP; recovery of ^{32}P radioactivity in hybrid, 4.2%; *c*, Pr-B RSV DNA equivalent to 500 pmol of dGMP; recovery in hybrid, 13.2%; *d*, Pr-B RSV DNA, equivalent to 80 pmol of dGMP; *e*, rabbit globin cDNA, $s_{20,w}$ about 9S (obtained from Dr Peter Curtis), 0.2 µg. *a′–c′* are tracings of *a–c*; *b′* also identifies the spots in *d*. The hatched bar in the tracing indicates the position of the gel strip from the first dimension.

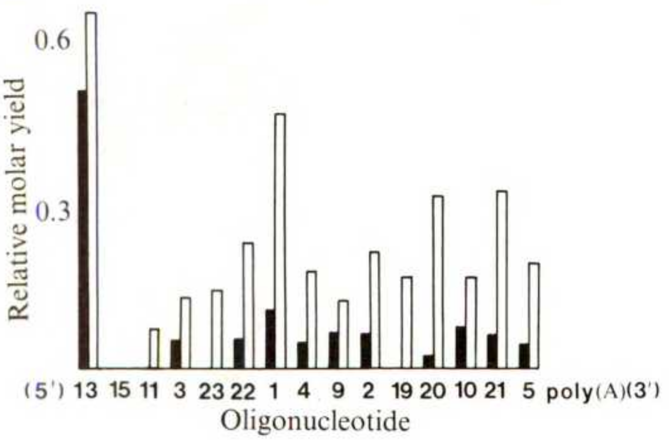

Fig. 2 Relative yields of some large T_1 oligonucleotides from Pr-B RSV ^{32}P-RNA recovered after hybridisation to Pr-B RSV RNA. The gel regions corresponding to the large T_1 oligonucleotides shown in the autoradiographs of Fig. 1*b* and *c* were excised, and the ^{32}P radioactivity (due to the hybridised RNA) and the ^{3}H radioactivity (due to the total Pr-B RSV RNA added as internal standard) were determined as described[17]. The relative recoveries were calculated by multiplying the $^{32}P/^3H$ ratio of each sample by a factor which takes into account the nucleotide composition of the particular oligonucleotide and the distribution of ^{3}H label between C and U, as described in the legend to Table 2 of ref. 17. The values (in arbitrary units; chosen to give approximately the estimated absolute yields) are plotted in the order of the oligonucleotide map as determined by Joho and Stoll (unpublished revision of the earlier map of Coffin and Billeter[17]). Solid bars represent the yields obtained after annealing at low, and open bars at high, DNA concentration.

had not been analysed or mapped previously since they are found in a gel region densely populated with smaller oligonucleotides. Figure 1*c* shows the fingerprint of T_1 oligonucleotides recovered after hybridisation at the higher DNA concentration. Again, T_{13} and T_1 were the strongest of the large and T_{51}, T_{52} and T_{53} of the smaller T_1 oligonucleotides; in addition almost all characteristic T_1 oligonucleotides were present, albeit with varying degrees of intensity. When globin-specific cDNA was substituted for RSV DNA the autoradiogram revealed the presence of poly(A) and some faint spots corresponding to smaller T_1 fragments but no large oligonucleotides (Fig. 1*e*). Thus, even the longest oligonucleotides generated by T_1 digestion of non-hybridised RSV RNA are not excluded by Sephadex G-100.

To measure the recovery of the individual oligonucleotides, the appropriate gel disks were excised, and the ^{32}P radioactivity as well as the ^{3}H radioactivity (from the internal standard) were determined. The relative molar yield of each ^{32}P-oligonucleotide was calculated by multiplying the ratio of its $^{32}P/^3H$ radioactivity by a factor which takes into account the base composition of the oligonucleotide and the distribution of ^{3}H label between UMP and CMP (see legend to Fig. 2 of ref. 17). The relative molar yields of selected large T_1 oligonucleotides which were well resolved on the autoradiogram and had been mapped earlier[17,18] (E. Stoll and R.H.J., unpublished results) are given in Fig. 2. Oligonucleotide T_{13}, which is recovered in highest molar yield (about 65% of the theoretical amount), had been mapped as the oligonucleotide closest to the 5′ end and, as shown below, in fact constitutes the 5′ terminus. Oligonucleotide T_1, which occurs in the next highest yield, is located in the middle of the map. After hybridisation at the lower DNA concentration the molar yield relative to T_{13} was 20% for oligonucleotide T_1 and 10% or less for all other nucleotides. At the higher DNA concentration the recovery of oligonucleotide T_1 was 70% compared with T_{13} while most other large oligonucleotides were present at 20 to 50%. Interestingly T_{15} and T_{11}, the two oligonucleotides closest to T_{13}, were barely detectable.

A similar protection experiment was performed with Pr-B RSV DNA fractionated on a neutral sucrose density gradient. Two fractions, one corresponding to a sedimentation coefficient of 0–4S and the other of 4–14S, were used for hybridisation. In both cases T_{13} was by far the most prominent of the large oligonucleotides, followed by T_1; T_{51}, T_{52} and T_{53} were again the most intense of the smaller oligonucleotides (data not shown). Figure 1*d* shows the result of an experiment in which the product recovered after hybridisation to cDNA was of strikingly low complexity; no spots besides T_{13}, T_{51}, T_{52} and T_{53} were present at a significant intensity.

Oligonucleotide T_{13}

Oligonucleotide T_{13} was digested enzymatically and the products were analysed. As shown in Table 1, pancreatic RNase digestion yielded, among other nucleotides, a product Xp (previously thought to be AAAC from its electrophoretic mobility[17,18]) which was not susceptible to further degradation by the combined action of RNases A, T_1 and T_2. This mixture yields mononucleotides from normal oligonucleotides. This resistance to digestion was reminiscent of the behaviour of the so-called capping group $m^7G^{5'}ppp^{5'}G^mpCp$ found at the 5′ terminus of RSV RNA by Keith and Fraenkel-Conrat[19] and Furuichi *et al.*[20]. To compare Xp with the authentic capping group, 30–40S Pr-B RSV ^{32}P-RNA was digested exhaustively with pancreatic RNase A, RNase T_1 and RNase T_2, and the digestion products were separated by two-dimensional electro-

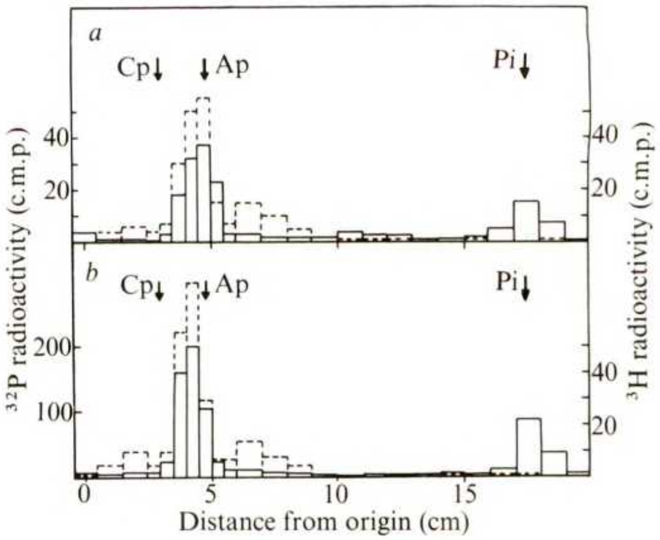

Fig. 3 Coelectrophoresis of ^{3}H-methyl-$m^7G^{5'}ppp^{5'}G^mpC_{OH}$ and the dephosphorylated ^{32}P-labelled putative capping group derived from oligonucleotide T_{13} and from 30–40S Pr-B RSV RNA. ^{32}P-labelled oligonucleotide T_{13} (7,000 c.p.m.) (*a*) and Pr-B RSV ^{32}P-RNA (3.4×10^6 c.p.m.) (*b*), prepared as described in the legend to Table 1 were digested in 10 µl of 7.5 mM sodium acetate (*p*H 4.5)–0.5 mM EDTA with RNase A (0.8 mg ml^{-1}) and a Takadiastase extract (containing RNase T_2 and T_1, about 80 U ml^{-1}, see ref. 32) for 2 h at 38 °C in the presence of 40–50 µg of yeast carrier RNA. The products were separated by two-dimensional electrophoresis as described by Adams and Cory[21]. In the case of (*a*) as well as of (*b*) a product (Xp and X′p respectively) with a mobility relative to Gp of 1.2 in the first, and 0.12 in the second, dimension was identified, in addition to the four standard nucleotides. X′p (990 c.p.m.) and Xp (225 c.p.m.) were eluted, mixed with 10 µg of yeast RNA and digested with 0.018 U of alkaline phosphatase from *E.coli* (Worthington) in 10 µl of 50 mM Tris-HCl (*p*H 8.8)–10 mM $MgCl_2$ for 60 min at 38 °C. The digests were mixed with about 1 A_{260} unit each of (3′)AMP and (3′)CMP, 0.1 µmol of unlabelled inorganic phosphate and ^{3}H-methyl-$m^7G^{5'}ppp^{5'}G^mpC_{OH}$ (about 2,000 c.p.m.; the preparation was a gift of Drs Furuichi and Shatkin) and subjected to electrophoresis on Whatman 3MM paper at *p*H 3.4 ^{32}P-phosphate was run in a parallel lane and located by autoradiography. The standard nucleotides were located in the ultraviolet light. Each lane, (*a*) and (*b*), was cut into strips which were placed in scintillation vials with 10 ml of toluene-based scintillator solution. ^{3}H radioactivity (— — — —) and ^{32}P radioactivity (————) were determined by scintillation counting. Background radioactivities (5 c.p.m. for ^{3}H, 9 c.p.m. for ^{32}P) were subtracted from each value.

Table 1 Digestion products of oligonucleotide T_{13}

RNases T_2+T_1+A	Pancreatic RNase A	RNAse U_2
0.82 Xp	0.8 Xp	0.8 X–C–Ap
5.4 Ap	3.0 A–Up	1.0 U–U–U–U–Ap
1.0 Gp	2.7 A–Cp	0.82 U–(C,U)–Ap
6.8 Cp	5.1 Cp	0.83 U–U–Gp
7.3 Up	5.1 Up	1.6 C–C–Ap
	1.0 Gp	1.0 C–Ap

Pr-B RSV ^{32}P-RNA (20×10^6 c.p.m.) was digested with RNase T_1, the products were separated by two-dimensional polyacrylamide gel electrophoresis and oligonucleotide 13 was extracted as described in ref. 17. Aliquots (1,000–3,000 c.p.m.) were digested with RNase U_2, pancreatic RNase A or with a mixture of RNases T_2, T_1 and A (for base analysis) as described[31]. The digestion products were separated at *p*H 3.5 on Whatman 3MM paper for base analysis and on DEAE paper in the other cases. The products of U_2 digestion were characterised by their mobilities and/or further digestion as for base analysis. The yields of all products were measured by scintillation counting. Molar compositions are relative to the underlined nucleotides; Xp, identified as the capping group (see text) contains five phosphate residues.

phoresis as described by Adams and Cory[21]. Oligonucleotide T_{13} was subjected to the same treatment in parallel. Pr-B RSV RNA yielded almost exclusively the four standard mononucleotides and about 0.042% of a product X′p with electrophoretic properties similar to those described for the capping group[21]. The mobility relative to Gp in the first dimension was 1.2, in the second 0.12; the corresponding values of Adams and Cory[21] were 1.1 and 0.092. Oligonucleotide T_{13} gave the four standard mononucleotides and 22.5% of a product Xp which had the same relative mobility as X′p. X′p and Xp were treated with phosphatase and subjected to one-dimensional electrophoresis. In both cases 22% of the radioactivity were released as inorganic phosphate (1.1 mol), and the residual oligonucleotides X'_{OH} and X_{OH} had the same electrophoretic mobility as authentic ^{3}H-CH$_3$-labelled.

$m^7G^{5'}ppp^{5'}G^mpC_{OH}$ was obtained from Dr A. Shatkin (Fig. 3). Digestion of X_{OH} and X'_{OH} with snake venom phosphodiesterase yielded inorganic phosphate and products with mobilities characteristic of 7mpG, pG and pC (data not shown). These experiments prove that oligonucleotide T_{13} contains the capping group and thus constitutes the 5′ terminus of Pr-B RSV RNA. From the data of Table 1 the partial sequence $m^7G^{5'}ppp^{5'}G^m$-C-C-A-(U_4A;U(C,U)A;2C_2A;CA)-U-U-Gp was deduced. Evidently the initiation codon A–U–G is not present within the first 25 nucleotides of Pr-B RSV RNA. It is of interest to note that in RAV-6 RNA the same capping group is associated with a large T_1 oligonucleotide of a somewhat different mobility which, with one exception, yields the same products as T_{13} on digestion with pancreatic and U_2 RNase and thus probably has a similar overall structure.

Initiation sites

We have demonstrated, by a new experimental approach, that a large proportion of the DNA synthesised *in vitro* by disrupted oncornavirus particles is complementary to a short segment of the viral RNA which contains the 5′ terminus, and a smaller proportion is complementary to almost all of the RNA sequences[10–12]. Our results confirm and extend the findings of Taylor and Illmensee[16]. These authors reported that the newly synthesised DNA, when isolated as a template–primer–product complex, is associated only with close to full-length, poly (A)-linked RNA and concluded that initiation occurs close to the 5′ end of the RNA. We found that a major fraction of *in vitro* cDNA with a sedimentation coefficient of 4S and less, that is, with chain lengths of certainly less than 200 nucleotides, hybridises to the 5′ terminal oligonucleotide (T_{13}) of Pr-B RSV RNA. The fact that the complexity of the RNA protected by the DNA is quite low, as judged by the appearance of only one large T_1 oligonucleotide in high yield and the virtual absence of the two T_1 oligonucleotides closest to the 5′ terminal fragment (T_{11} and T_{15}), argues against the possibility that the short size of our product was due to endonucleolytic cleavage (see also refs 7 and 9). Thus, the major initiation site must lie within 200 nucleotides from the 5′ terminus of the RNA, and the short size of the DNA could be explained if the 5′ end of the RNA constituted a termination point for a large part of the product transcribed *in vitro.*

DNA complementary to an RNA segment located in the middle of the genome was present at a level about 20% of the major DNA species, as judged by the relative amounts of oligonucleotides T_1 and T_{13} recovered after hybridisation at low DNA concentration. DNA sequences corresponding to other regions of the RNA, in particular close to the 3′ end, occurred each at less than 10% of the major species since in the hybridisation at high DNA concentration the characteristic large oligonucleotides were recovered with a yield half or less that of T_1. The occurrence of short cDNA species, corresponding to RNA segments located throughout the genome and present in significantly different amounts, suggests that DNA synthesis is initiated at not only one but more likely several additional sites throughout the RNA. Multiple initiation sites for cDNA synthesis have also been proposed by Rothenberg and Baltimore[22] for the murine leukaemia virus system. This proposal runs counter to the previous findings that all DNA synthesised *in vitro* initiates with the same nucleotide sequence at the 3′ end of a unique tRNA[13,14,15] associated with the 5′ end of 36S viral RNA[16]. The results were obtained, however, in the presence of only three deoxyribonucleoside triphosphates, that is, under conditions of limited synthesis, which might favour initiation at the main initiation site. Furthermore, in our experiments viral cDNA was synthesised in the presence of actinomycin D to suppress synthesis of double-stranded DNA[23,24]. cDNA synthesised in the presence of this drug (or of Mn^{2+}) has a higher complexity than that produced in its absence[12]; perhaps actinomycin favours the utilisation of minor initiation sites.

If DNA synthesis initiates at the 5′ terminal region by the addition of deoxynucleotides to $tRNA^{Trp}$, how does DNA synthesis originate at the other minor initiation sites? It has been assumed that the position defined by the 3′ terminus of the primer tRNA hydrogen-bonded[25–27] to viral RNA constitutes the attachment site for the RNA-dependent DNA polymerase. Panet *et al.*[28], however, have shown that the enzyme has a strong affinity for free $tRNA^{Trp}$; it is thus conceivable that a preformed polymerase–tRNA complex may initiate at many different sites, albeit with low efficiency. Alternatively (or in addition) a low level of initiation could occur at sites defined by the many other tRNAs[13,28,29] associated with 70S RNA, or possibly at the 3′ termini of accidental nicks in the 70S RNA, which could serve as primer template.

We do not know to what extent the *in vitro* findings with disrupted virus particles reflect the events which lead to the formation of a complete viral DNA transcript *in vivo.* If we assume, however, that the physiological initiation site is in fact located close to the 5′ terminus then one must postulate a transcription mechanism that allows polymerase molecules to continue elongation at the 3′ terminus, either of the same or a second molecule of the viral RNA. A model in which this feature is postulated was proposed by Cooper and Wyke[30]. Recently, it has been reported[7,8,22] that in appropriate reaction conditions the length of a small fraction of the cDNA synthesised by disrupted viral particles approaches that of the viral RNA. It will be of interest to ascertain whether DNA initiated at a site closer to the 3′ terminus is elongated extensively or whether DNA beginning close to the 5′ terminus is efficiently elongated across the (possibly ligated) gap between a 5′ and a 3′ terminus.

We thank Drs Furuichi and Shatkin for the gift of ^{3}H-methyl-$m^7G^{5'}ppp^{5'}G^mC_{OH}$ and Dr Curtis for rabbit globin cDNA. L.M.C. was supported by an NIH fellowship. This project was supported by the Schweizerische Nationalfonds.

Proviral sequences of baboon endogenous type C RNA virus in DNA of human leukaemic tissues

Flossie Wong-Staal, David Gillespie & Robert C. Gallo

Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Maryland 20014

Hybridisation of RNA from a baboon endogenous type C RNA virus to DNA from tissues of leukaemic patients indicates that a virus of this type is horizontally transmitted among humans. DNA from several patients with leukaemia hybridised 70% of the hybridisable RNA from baboon endogenous type C RNA virus (BaEV) and yielded hybrids of high t_m*, whereas DNA from normal human tissues hybridised only 23% of the BaEV RNA, and the* t_m *of these hybrids was lower.*

SEVERAL studies link type C RNA viruses to human leukaemia. These include the detection of subviral components within blood leukocytes taken from leukaemic patients[1–11], the transient release of virus-like particles from these cells in short term culture[12,13] and the rare isolation of infectious virus from cultured human cells[14–19]. Nevertheless, evidence for the viral aetiology of human leukaemia or, in fact, for the presence of oncornaviruses in humans has been limited by the inability to detect in fresh human tissues one component expected of virus-infected cells, namely, a DNA provirus related to a major portion of the genome of a type C RNA virus[20].

The detection of a DNA provirus requires the availability of an appropriate viral nucleic acid for use as a detection probe. Early studies suggested that Rauscher mouse leukaemia virus ($MuLV_R$) might yield a useful probe[8–11], but subsequent work indicated that the $MuLV_R$-related RNA sequences detected in leukaemic blood leukocytes might also exist in the blood cells of normal people[4] and that these sequences might be more closely related to that of the primate RNA tumour virus, simian (woolly monkey) sarcoma-leukaemia virus (SiSV)[4,6,7]. So far, neither RNA probes from SiSV nor from $MuLV_R$ have been used successfully to detect DNA proviruses in human tumour cells[4].

The isolation of infectious virus from cultured human cells has provided a new impetus in the search for provirus in human cells. In one instance[14,15] the viruses obtained from cultured human leukaemic cells consisted of a mixture of two type C viruses; one closely related to SiSV and one closely related to viruses obtained from apparently normal baboons, the baboon endogenous virus, BaEV[21–24]. This result prompted us to examine various tissues from leukaemic patients for BaEV-related provirus. Evidence for BaEV-related provirus has very recently been reported in DNA from the spleen of the one particular patient, patient HL23, with acute myelogenous leukaemia (AML)[25] whose cells in culture had released virus, the HL23 virus (HL23V)[14]. We present here detailed hybridisation results that demonstrate the presence of BaEV-related provirus in seven of the leukaemic tissues studied and its absence from normal tissues. Specifically, these leukaemic tissues were chosen because of earlier evidence for the presence of other viral components in them. We also show that DNA sequences distantly related to BaEV were found in both normal and leukaemic humans.

BaEV sequences in human DNA

Figure 1 shows that more of the sequences in RNA from BaEV hybridised to DNA from spleens or peripheral blood leukocytes of some patients with myelogenous leukaemia than to DNA of tissues obtained from normal humans. DNA from some leukaemic patients (HL23, HL49) hybridised faster to BaEV RNA than did DNA from other patients but by a C_0t of 2×10^4 (200 h) DNA from all of the leukaemic patients presented in Fig. 1 hybridised significantly more BaEV RNA than did DNA from normal humans. It was not possible to extend the hybridisations longer than 200 h because of RNA degradation (dashed line, Fig. 1). DNA from human NC37 cells infected by BaEV should contain one provirus per haploid genome[23,24], and in this case BaEV sequences were readily detected (Fig. 1). Since the hybridisation conditions used detected DNA sequences present in one or more copies per haploid genome, the low hybridisation obtained with DNA from normal humans, relative to leukaemics, suggests that the sequences in the leukaemic DNA do not result from amplification of normal human chromosomal genes. In fact, the BaEV sequences in the DNA of some leukaemic patients (HL7, HL11) were probably present less than once per cell, as judged by the rate of hybridisation with BaEV RNA ($C_0t_{1/2}\sim10^4$) (Fig. 1).

The experiments shown in Fig. 1 used a DNA : ^{125}I-RNA ratio of about 2×10^7 : 1 To determine whether this ratio represented an excess of BaEV-related DNA sequences, hybridisations were carried out with varied DNA : RNA ratios ($C_0t = 2\times10^4$) (Fig. 2). The percentage ^{125}I-RNA hybridised to DNA against the DNA : RNA ratio is shown in Fig. 2*a*. The results indicate that even at the highest DNA : RNA ratio examined, the percentage of the RNA hybridised was still increasing. The data of Fig. 2*a* were therefore subjected to a double reciprocal analysis and the resulting curves were extrapolated to the *Y* axis (where RNA : DNA approaches 0, DNA : RNA approaches ∞) (Fig. 2*b*), to estimate the fraction of BaEV RNA that may hybridise at infinite DNA excess. The results (maximum percentage of the BaEV RNA hybridised at infinite DNA) shown in Table 1 demonstrate that DNA from some leukaemics hybridised 70% of the hybridisable BaEV RNA whereas DNA from normal human tissues hybridised only 23% of the RNA at DNA excess. Most extrapolated values were close to actual values obtained with large (1 mg for example) DNA inputs; where this was not the case, the actual values obtained were used (values in parentheses). BaEV sequences in the DNA of one patient (HL54) were detectable by DNA titration analyses and especially by the double reciprocal representation (Fig 2*b*), although they were not detected in kinetics experiments. The analysis of DNA from four tissues of normal persons (Table 1) establishes the lack of BaEV sequences in the normal human genome. The possible existence of some normal tissues with BaEV sequences or many normal tissues with very rare BaEV sequences (less than one copy per cell) is not evaluated here and would indicate infection of normal individuals.

Lack of detectable SiSV proviral sequences

As we have noted, some biochemical studies have indicated that leukaemic cells may sometimes contain molecules related to components of woolly monkey (simian) sarcoma–leukaemia virus, SiSV (refs 1–7, 13–19, 25, 28–30) and four laboratories have reported the release of infectious virus related or identical to SiSV from cultured human cells[14–19]. The case of patient HL23 (refs. 14–16, 25) involved release of an SiSV-related virus in addition to a virus closely related to BaEV.

In earlier work[4,5], however, it was not possible to detect proviral DNA related to the genome of SiSV in leukaemic patients. Since the DNA titration experiments detected BaEV sequences in DNA from leukaemic patients, this assay was applied to RNA from SiSV. Figure 2*c* nevertheless shows that no proviral sequences related to SiSV could be detected in tissues of patient HL23. DNA from normal humans hybridised very little of the SiSV RNA at finite DNA inputs, relative to the amount of BaEV RNA that was hybridised (Fig. 2*c*). Although sequences very distantly related to SiSV RNA may exist, inordinate amounts of DNA would be required for the formation of stable hybrid structures. It seems, therefore, that if the human leukaemic cells are infected by SiSV, the infection does not involve the classical mechanism of inserting one or more proviral DNA sequence per transformed cell. It remains possible, however, that provirus related to SiSV will be found in other patients.

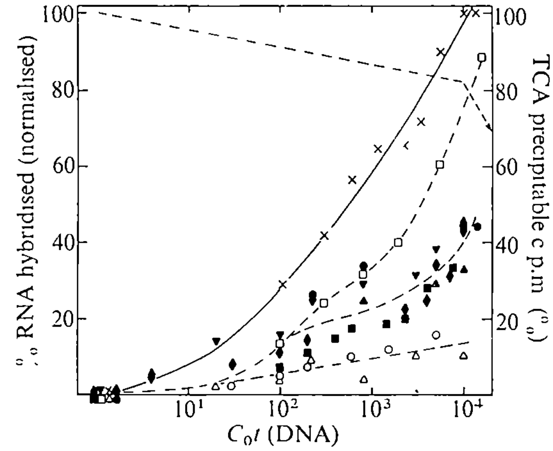

Fig. 1 Kinetics of hybridisation of BaEV RNA to cell DNA. Hybrids were formed between ^{125}I-RNA from BaEV (strain BAB8-K(FCf2TH)[9] (500–1,000 c p.m.; 10^8 c.p m μg^{-1}) and a 1×10^7- or 2×10^7-fold weight excess of cell DNA at 60 °C in 0.4 M phosphate buffer and monitored by resistance to RNase as detailed elsewhere[25]. Fifty-five percent of the RNA hybridised to DNA from normal baboons and all values have been normalised to this result. ×, Yellow baboon spleen (*Papio cynocephalus*); ○, NC37 human lymphoid cultured cells derived from a normal donor; □, NC37 cells infected by BaEV (NC37(BaEV)); ●, blood leukocytes of patient HL49, a 32-yr-old male Caucasian with CML (acute phase), a white blood cell (WBC) count of 1.4×10^5 μl^{-1}—treatment records were not available; ▼, blood leukocytes of patient HL50, a 62-yr-old male Caucasian with AML, a WBC count of 2.5×10^5 μl^{-1}—untreated; ▲, spleen taken at autopsy of patient HL23, a 51-yr-old female Caucasian with AML and under treatment with cytosine arabinonucleoside, vincristine, and prednisone; ◆, blood leukocytes from patient HL7, a 26-yr-old male Negro with CML (acute phase), WBC count of 6×10^5 μl^{-1}, and treated with prednisone and vincristine; ■, spleen taken at autopsy from patient HL11, a 59-yr-old male Caucasian with an unusual aggressive form of CMML and treated with hydroxyurea; △, liver taken from a normal human; — — — —, acid-precipitability of RNA. HL, human leukaemic; AML, acute myelogenous leukaemia; CML, chronic myelogenous leukaemia; CMML, chronic monomyelocytic leukaemic

Table 1 Maximum hybrid yield and t_m with BaEV RNA

Source of DNA	Disease	Maximum % RNA hybridised	t_m(°C)	Δt_m(°C)
HL23 spleen	AML	70	76	−1
HL50 leukocytes	AML	70	77	0
HL49 leukocytes	CML-A	70	78	+1
HL7 leukocytes	CML-A	(70)	79	+2
HL11 spleen	CMML	45	80	+3
HL54 leukocytes	AML	(40)	NT	—
HL51 spleen	AML	(30)	NT	—
HL55 leukocytes	ALL	(23)	NT	—
Normal human spleen	—	23	NT	—
Normal human liver	—	23	69	−8
Normal human blood leukocytes	—	23	NT	—
NC37 normal human lymphoid cell line	—	23	69	−8
NC37 (BaEV)	—	100	77	0
Normal baboon spleen	—	100	75–78*	—
Human leukocyte (× rRNA) (control)	—	—	82	—

The maximum percentage of the BaEV RNA that hybridised to DNA was estimated from Fig. 2*b*. t_m Values were measured as described in the text. Leukocytes, peripheral white blood cells; AML, acute myelogenous leukaemia; CML-A, acute phase of chronic myelogenous leukaemia; CMML, a case of aggressive chronic monomyelocytic leukaemia. The HL numbers correspond to those in earlier publications (refs 1–7, 14–16, 25, see also legends to Figs 1 and 2); NC37(BaEV), NC37 infected by BaEV. NT, not tested.

*Value varied with different species of baboon.

Thermal stability of hybrids formed with BaEV RNA and DNA from leukaemic patients

The thermal stability of hybrids formed at 60 °C was measured by exposure to a given temperature for 5 min in 0.15 M NaCl and then for 2 h at 37 °C in 0.45 M NaCl with RNase. Representative results are shown in Fig. 3 and are presented in entirety in Table 1. The thermal transitions of all BaEV RNA hybrids examined were broad. The t_m values of hybrids formed with DNA from positive leukaemic tissues were higher than that of hybrids formed with DNA from normal human tissues. They approached t_m values observed with hybrids formed between rRNA and cell DNA and, in fact, were higher in some instances than the t_m of hybrids formed with RNA of BaEV and DNA from normal baboons. Thus, whereas the BaEV-related sequences in DNA of normal baboons and human leukaemic tissues seem to be heterogeneous, they are equally closely related to RNA of BaEV. In contrast, the sequences in the DNA of normal human liver or NC37 cells differ more in nucleotide sequence from BaEV RNA and are therefore distinct from the more closely BaEV-related sequences in the spleens of leukaemic patients HL11 and HL23 and in the blood leukocytes of patients HL7, HL49, and HL50 (Table 1).

Phylogeny of BaEV RNA

Acceptance of the conclusion that the human leukaemic tissues contain BaEV DNA sequences is obviously contingent on the source of the ^{125}I-RNA and the DNA used. The genetic origin of the BaEV RNA could be tested by hybridising the RNA to DNA of selected primates. These experiments were not complicated by contamination with cell RNA since the BaEV used was obtained from canine thymus cells and therefore any contaminated cell RNA would be non-primate. On the basis of the data of Benveniste and Todaro[23,24] BaEV RNA would be expected to hybridise best to animals most phylogenetically related to baboons, and we found it to be so (Fig. 4). The data are presented as a double reciprocal analysis of DNA titration experiments using DNA from selected primates. The BaEV RNA was most closely related to DNA from baboons, of 18 Old World monkeys tested to date (Fig. 4 and L. Donehower, R. C. G., F. W.-S., and D. G., in preparation). The phylogenetic data and the hybridisation to proviral DNA in NC37 (BaEV) cells (Fig. 1) confirm that the ^{125}I-RNA was the labelled genome of BaEV.

Table 2 Hybridisation of type-specific ^{125}I-DNA to cell DNA

Source of unlabelled cell DNA	Source of ^{125}I type-specific DNA	
	Baboon (*P cynocephalus*)	Human
	% Hybridisation of subfamily-specific ^{125}I-DNA (±10)	
Human leukaemic tissues		
HL23 spleen	0	118
HL50 leukocytes	0	110
HL7 leukocytes	3	95
HL54 leukocytes	8	96
HL11 spleen	5	106
HL49 leukocytes	0	118
Human normal leukocytes	0	100
Normal primate tissues		
Yellow baboon spleen (*P. cynocephalus*)	100	0
Mandrill baboon brain (*P. sphinx*)	93	4
Macaque muscle (*Macaca mulatta*)	91	—
Sooty mangabey spleen (*Cercocebus atys*)	95	7
De Brazza guenon spleen (*Cercopithecus neglectus*)	0	—
Colobus (*Colobus abasinicus*)	0	0

DNA purified from tissues of a baboon (*P. cynocephalus*) and fragmented to a chain length of about 500 nucleotides was labelled with ^{125}I (3×10^7 c.p.m. μg^{-1}) by W. Prensky. It was self-annealed in 0.14 M PO_4 to a C_0t of 5 at 70 °C. Reannealed DNA was bound to hydroxyapatite (HAP) at 80 °C, unannealed DNA was washed from the HAP at 80 °C, and reannealed DNA was eluted at 100 °C. The ^{125}I-DNA eluting between 80 and 100 °C was mixed with a 10^5-fold weight excess of unlabelled genomic DNA from Old World primates, incubated at 100 °C to denature any double-stranded DNA, annealed at 80 °C for 15 min, and hybridised ^{125}I-DNA was purified on HAP as described above. ^{125}I eluting between 80 and 100 °C was scored as hybrid. Of the hybridisable ^{125}I-baboon DNA, two-thirds was specific for baboons, mangabeys, and macaques and one-third was less specific sequences which were conserved among all Old World primates tested, excluding prosimians. The more specific sequences were used for constructing Table 2 The units presented are percentages of "type-specific" hybridised relative to that hybridised to *P. cynocephalus* DNA and were reliable within ±10 units (±10% of the maximal value). The rationale for the experiment was that repeated sequences originating after man and baboon diverged from a common ancestor would be present in one of the animals and would be totally lacking in the repeated sequence fraction of the other. It has developed that these sequences are present in the fraction of genomic sequences that reanneal by a C_0t of 1–5 (repeated some 1,000 times) and that have a high thermal stability

Typing of DNA

This laboratory uses DNA from many non-human primates. Although obviously a very remote possibility, it was conceivable that the results described here were due to the selective, accidental contamination of the leukaemic tissues with primate tissues, with baboon tissue for example. An assay was devised therefore to ensure that the putative DNA preparations from human leukaemics were, in fact, human DNA. A specific ^{125}I-DNA probe was prepared from the repeated sequence populations of baboon and human DNA using the rationale of Rice[26] (Table 2). The baboon DNA probe had two useful properties: (1) in reconstruction experiments it detected very low amounts of baboon DNA (1%) in solutions of human DNA; and (2) it contained a very specific sequence component present in some members of the subfamily *Cercopithecinae* (baboons, macaques, and mangabeys) that was completely absent from other members of the same subfamily (guenons) as well as from other primates (other Old World monkeys, apes, prosimians, New World primates) (Table 3 and our unpublished data). Hybridisation experiments using the specific sequences from the DNA of baboons and humans and the unlabelled DNA preparations examined here showed that the human leukaemic DNA samples lacked baboon-specific sequences (Table 2), establishing that the hybridisation results obtained with BaEV RNA could not be explained by contamination of the human leukaemic DNA preparations with baboon DNA.

Interpretation of molecular hybridisation results

We conclude that five of the eight human leukaemic cases presented here had DNA sequences related to a major portion of the BaEV genome and that these sequences were absent from the normal human genome. In three of these cases, HL7, HL49, and HL50, DNA was prepared from fresh, unfrozen cells in 1974 and 1975. Aliquots of cells from these patients were stored frozen and DNA was again prepared from them in 1976. They were again positive and showed the same hybridisation kinetics as with DNA from the unfrozen cells. Therefore, the detection of BaEV proviral DNA in the positive patients was reproducible. Two other cases, patients HL51 and HL54, may also be positive (Table 1), but there was not enough DNA available for t_m analyses. The most plausible explanation of the molecular hybridisation findings is that the BaEV sequences were introduced from without by a viral agent and thus they merit the designation 'proviral' DNA sequences.

In summary, the supporting evidence is as follows. Kinetic, stoichiometric (DNA titration), and thermal stability measurements all indicated the presence of BaEV sequences in DNA from some human leukaemic tissues. Kinetic analyses showed that most of the BaEV proviral sequences in leukaemic DNA were infrequent ($C_0t_{1/2} > 10^4$), probably present at 0.1–1 copy per haploid genome. Stoichiometric studies showed that up to 70% of the hybridisable sequences in BaEV RNA were hybridised by DNA from spleens or blood leukocytes of leukaemic

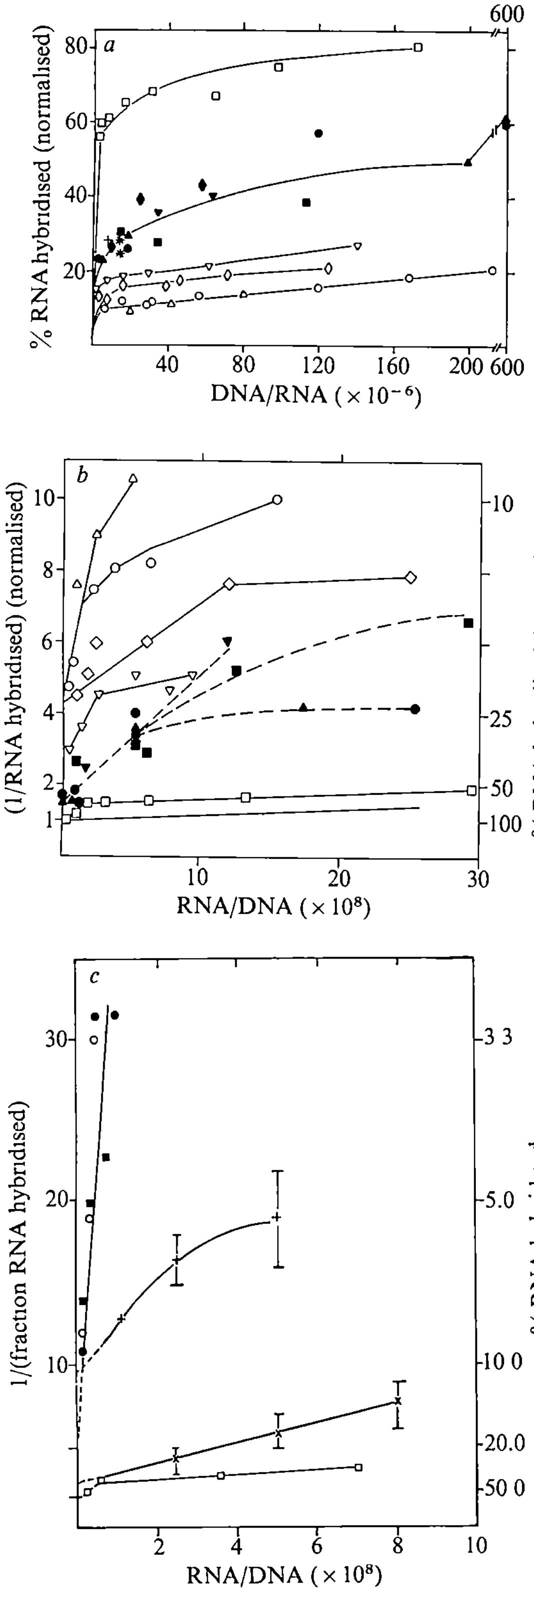

Fig. 2 Stoichiometry of hybridisation of BaEV RNA and SiSV RNA to cell DNA (DNA titration). Hybrids were formed between ^{125}I-RNA (10^8 c.p.m μg^{-1}) and cell DNA at 60 °C in 0 4 M phosphate buffer and a C_0t of 2×10^4 Hybrid formation was monitored by resistance to RNase *a* and *b*, Hybridisations with BaEV RNA. ○, NC37 human lymphoid cultured cell line derived from a normal donor, □, NC37 cells infected by BaEV; ●, blood leukocytes from patient HL49; ▼, blood leukocytes from patient HL50, ▲, spleen from patient HL23; ◆, blood leukocytes from patient HL7; ■, spleen from patient HL11; △, liver from a normal human; *, liver from patient HL51, a female Caucasian with AML and a white blood cell count of 5×10^5 μl^{-1}, other data not available; +, spleen from patient HL51; ◇, leukocytes from patient HL55, a 12-yr-old female Caucasian with ALL, other data not available; ▽, blood leukocytes from patient HL54, a 30-yr-old male Caucasian with AML. ——, *P. cynocephalus* spleen. ALL, acute lymphocytic leukaemia Results are normalised to the maximum hybridisation value obtained with DNA from *Papio cynocephalus* (55% of the RNA). *c*, Hybridisations with SiSV RNA. Hybrids were formed as described for *a* and *b*, but using ^{125}I-RNA from SiSV produced by NC37 cells. ■, NC37 normal human lymphoid cultured cell; □, NC37 cells infected by SiSV (NC37(SiSV)); ○, kidney from patient HL23; ●, spleen from patient HL23. For direct comparison, the results of *b* with BaEV RNA hybridised to normal (+) or leukaemic (×) human DNA are superimposed. Only the leukaemics described by solid symbols in *b* were used. The bars represent the high and low values obtained at each RNA:DNA ratio in *b* The results of *c* are not normalised. Note the differences in scales from *b*.

patients, compared with 23% hybridised by DNA from tissues of different normal humans, including liver, spleen, fresh blood leukocytes, and a cultured lymphoid cell line (NC37). The absence of the extra BaEV-related sequences in any one such tissue demonstrates that they are not Mendelian genes in normal humans and therefore do not arise in leukaemic DNA by amplification of normal human genes. Thermal stability measurements showed that among the BaEV-related sequences in the leukaemic tissues were some more closely related to BaEV RNA than any detected in normal human DNA. More specific conclusions, that is, the percentage mismatching, are premature because the DNA sequences involved seem to be heterogeneous, including the multiple BaEV sequences in normal baboons, and the t_m values obtained are an average of the stabilities of all of the RNA–DNA hybrids formed. Of the three measurements used, the DNA titration assay was the most sensitive for detecting BaEV proviral sequences.

Possible horizontal transmission of BaEV among humans

Though the sequences in human leukaemic DNA clearly qualify as BaEV sequences in the three molecular hybridisation assays described above, it was nonetheless initially surprising to find that a baboon type C virus, particularly a virus closely related to the one obtained from *Papio cynocephalus* (yellow baboon) had entered humans. In retrospect the concept is consistent with the following facts. (1) A BaEV-related P30 protein has been reported in human cells, including human leukaemic cells[28–30]. Although this was interpreted as expression of a human endogenous virus, which in theory may be related to BaEV, infection by exogenous BaEV itself is also consistent with the observed results. (2) Cross-species transmission of type C RNA viruses is now a well documented event[23,24,27]; in fact, one of the cases involved transmission of an ancestral BaEV to cats, probably in the Mediterranean basin[23,24]. (3) Although probably all Old World monkeys carry endogenous type C RNA viruses, only from baboons has the virus been isolated[21,22]. Thus, baboons seem to release BaEV with relative ease from many tissues. The virus is not completely controlled by its host and so is a candidate for infection between species. (4) BaEV grows readily in human cells. (5) *Papio cynocephalus* and its closely related kin, *Papio anubis* (dogface baboon), are found in Africa and could have had contact with primitive man. Once BaEV entered man it could then be transmitted with or without an intermediate vector among the human population (a phenomenon which we propose is occurring today). It seems that the transfer to man occurred recently since cases where cross-species transmission of type C RNA viruses apparently occurred more than 5 Myr ago resulted in more genetic change of the viruses isolated from the new host[23,24]. This is in contrast to the minimal differences between the BaEV RNA genome and the BaEV sequences in DNA of human leukaemics, or the sequences in the RNA of the BaEV component of HL23V.

The virus we call HL23V is similar and possibly identical in one of its two major components to BaEV[14,15]. It was repeatedly isolated from cultures of marrow and blood cells from patient HL23, with acute myelogenous leukaemia[16].

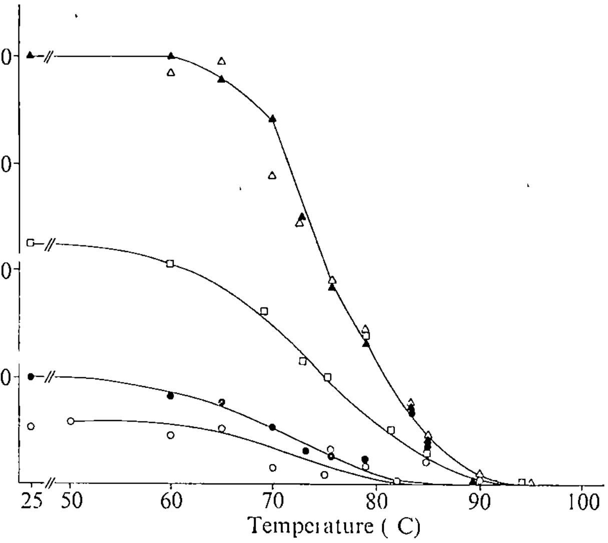

Fig. 3 Thermal stability of BaEV RNA-cell DNA hybrids Hybrids were formed between ^{125}I-BaEV RNA and a 5 × 10^6-fold weight excess of cell DNA at 60 °C in 0 4 M phosphate buffer and a C_0t of 2 × 10^1- The melting of the hybrid was accomplished as outlined in the text and in ref. 25 The t_m values for Table 2 reflect melting of half of the hybrids resistant to incubation at 60 °C. ●, NC37 normal human lymphoid culture cell line; ○, liver from a normal human, □, spleen of patient HL23; ▲, spleen of *P cynocephalus;* △, spleen of *P. anubis.*

The DNA purified from the spleen of this patient contains BaEV sequences (ref. 25 and this article) and the cytoplasm of the patient's fresh, uncultured, blood leukocytes contained virus-like particles with BaEV-related nucleic acids[25]. It will be of considerable interest now to see whether the RNA of this BaEV-related virus will detect more proviral sequences in the DNA of many human leukaemic tissues than did the RNA of the BaEV isolated from baboons.

It is also of interest that another patient with BaEV provirus (HL51) was a close contact of patient HL23, a woman who presented with AML slightly before HL23 and who ultimately died of the disease. That both leukaemic contacts had BaEV provirus could be significant. Though all the tissues examined in this study were from patients who were found earlier to possess other types of viral components[1-7,15,25], and most of them were positive for BaEV sequences, a more random survey of leukaemic patients is in progress and results obtained to date suggests that only about 20% of patients with myelogenous and lymphocytic leukaemia contain BaEV provirus in their blood leukocytes (N. Miller *et al.*, in preparation). We feel that BaEV may not be the only type C virus infecting the human population. Our results should be interpreted in the context of the detection of: (1) proviral sequences distantly related to Rauscher mouse leukaemia virus in DNA of some patients with leukaemia or lymphomas (G. Aulakh, D. G., and R. C. G., unpublished); (2) 'extra sequences', some related to RNA of Rauscher mouse leukaemia virus, in DNA of blood leukocytes of several patients with leukaemia but missing in DNA of blood leukocytes from normal persons[10,11,31]; (3) RNA related to Rauscher mouse leukaemia virus[8,9], Moloney mouse leukaemia virus[32], and simian sarcoma–leukaemia virus in blood leukocytes of some leukaemic patients (A. Tavitian, personal communication); (4) antibodies in humans directed against viruses of the HL23V-SiSV-gibbon ape leukaemia virus and BaEV families[33,34] and, less frequently, different antibodies directed against feline and mouse leukaemia viruses[34]; and (5) antigens in tissues of some humans related to those of baboon endogenous virus[28-30], simian sarcoma–leukaemia virus[29,30], and Friend mouse leukaemia virus[35]. Apart from such unlikely explanations as the discarding of particular DNA sequences during normal differentiation, and their selective retention in some leukaemic people, information storage in RNA of normal cells, or unstable episomal DNA sequences[36], the more likely possibility is that many RNA tumour viruses originating in animals are being horizontally transmitted among humans. Whether they are pathogenic in humans remains to be established, but the majority of reports suggesting the absence of type C RNA virus components in tissues of normal humans (but see ref. 4) suggests that their potential pathogenicity in humans should be considered. In any case, we feel the present results establish the presence of type C RNA virus information in humans.

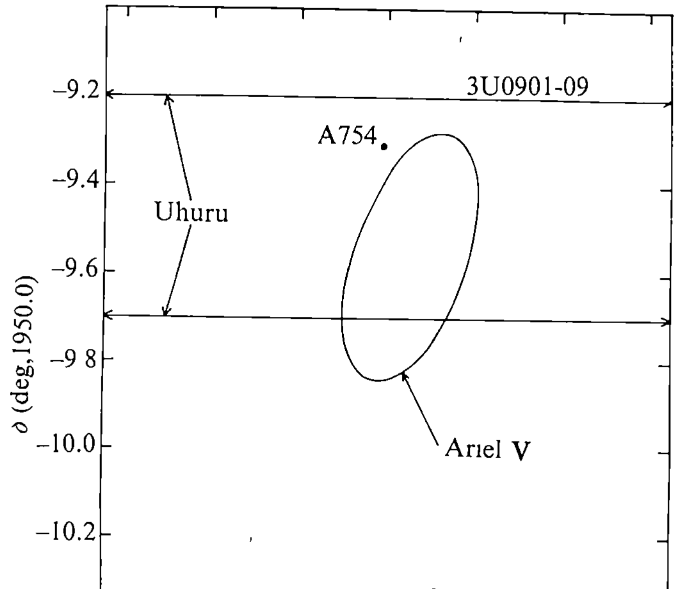
Identification of Abell Cluster 754 with the X-ray source 3U0901 – 09 by Ariel V

THE faint, high galactic latitude X-ray source 3U0901−09 (ref. 1) has been previously associated[2], on positional grounds, with the rich cluster of galaxies, Abell 754 (distance class 3, richness class 2)[3]. Since the Uhuru 90%-confidence positional error box for 3U0901−09 is relatively large, having an area of 2.6 degree[2], it is worthwhile, in view of current theoretical interest in X-ray emission from clusters of galaxies (see, for example, ref. 8), to reduce the positional uncertainty and thus confirm or reject the proposed identification with A754.

The high energy (2–18 keV) detector system of the Ariel V X-ray sky survey instrument (SSI) has observed 3U0901-09 on a number of separate occasions over a period of a year (February 1975–February 1976) and the results are reported here. The SSI and data analysis are described elsewhere[4–6].

The SSI measured a statistically significant signal (> 3σ) from the vicinity of 3U0901-09 for nine sets of observations. The individual error boxes ('lines of position') from each set of SSI observations are combined to produce the Ariel V Sky survey 90%-confidence probability contour for the source location, shown in Fig. 1. This reduces, by over an order of magnitude, the uncertainty in the location of the X-ray source and supports the previous identification[2] of 3U0901–09 with A754. Our 90%-confidence error box has centroid (in celestial coordinates (degrees, 1950.0)) $\alpha=136.55$, $\delta=-9\ 56$, and area 0.11 degree[2]. We have paid particular attention to the possibility that A761 might also be a source of significant X-ray emission; careful examination of the individual observations, however, allows us to reject this possibility.

Fig. 1 90%-confidence positional error boxes for the X-ray source 3U0901-09 associated with A754, from Ariel V and Uhuru.



Each observation consisted of a summation of data over a period of 1–3 d. There is no significant intensity variation between the individual measurements (maximum deviation from the mean is ~1σ), and the mean intensity level is 1 9±0.2 Ariel V counts s^{-1} (2–18 keV), corresponding to ~ $(9.5\pm0.9)\times10^{-11}$ erg cm^2 s^{-1} (2–10 keV) or 5.5±0.5 Uhuru counts s^{-1} (2–6 keV), assuming a spectrum like that of the Coma cluster The uncertainties quoted are from Poisson errors on the count rates only. This is in close agreement with the Uhuru measurement[1,2] of 4.4±0.8 Uhuru counts s^{-1}. A redshift $z=0\ 0537$ for A754 (ref. 7) and a Hubble constant of 55 km s^{-1} Mpc^{-1} give a distance of 293 Mpc, implying, from the Ariel V intensity, an X-ray luminosity of $(9\ 8\pm0.9)\times10^{44}$ erg s^{-1} (2–10 keV).

It has been suggested that cluster X-ray luminosity can be positively correlated with: (1) cluster richness[8,10]; (2) cluster radio luminosity[9]; (3) the presence of one or more dominant central galaxies (usually optical type *cD* (ref. 11))[9,10]; possible explanations have been discussed in the literature[9,10,12]. Confirmation of A754 as an X-ray source strengthens these apparent correlations, A754 being both a *cD* type cluster[11] and a radio source[9]. Several theoretical studies of possible X-ray emission mechanisms in clusters of galaxies (see those reviewed in ref. 8), have suggested (differing) correlations between cluster X-ray luminosity and velocity dispersion Δv. It is therefore important to measure Δv for A754.

The Ariel V project is supported by the SRC.

Inverse Compton spectra and the spectrum of Cygnus X-1

THE many X-ray observations of the black hole candidate Cyg X-1 show a variable power-law spectrum (see refs 1–8)

$$\frac{\mathrm{d}L}{\mathrm{d}E} \simeq (2\text{–}6)\times 10^{35}\,\mathrm{erg\,s^{-1}\,keV^{-1}}\left(\frac{E}{10\,\mathrm{keV}}\right)^{-p}\left(\frac{d}{2.5\,\mathrm{kpc}}\right)^{2} \qquad (1)$$

where d is the distance to the source. During the 'low state', in which the source spends ~90% of its time[7], $p \simeq 0.5$ and the power-law spectrum extends over 1 keV $\lesssim E \lesssim$ 100 keV, with a knee suggested at ~100 keV. During the transient 'high state', which persists for weeks to months, the total luminosity at $\gtrsim$ 1 keV increases by a factor 5–10 and the spectrum steepens to $2 \lesssim p \lesssim 4$ over the range 1 keV $\lesssim E \lesssim$ 10 keV. A hard excess above this steep slope is visible at > 10 keV, which contains ~10% of the total energy. In this paper we glean some information about the physics of the source by interpreting this spectrum as being caused by inverse Compton scattering by nonrelativistic electrons at a temperature $T_e \simeq 10^9$ K.

A power-law spectrum can arise from two familiar mechanisms when there exists a power-law distribution of ultrarelativistic electrons, namely inverse Compton scattering or synchrotron radiation. Recently, several workers[8–11] have pointed out a third mechanism that produces a power-law spectrum: repeated inverse Compton scattering of initially soft photons by a non-relativistic, thermal electron distribution in a finite cloud, optically thin for emission and absorption. If the soft photons are injected into the cloud with a characteristic photon energy E_s and spectrum $\mathrm{d}L_s/\mathrm{d}E$, then the emergent hard spectrum is

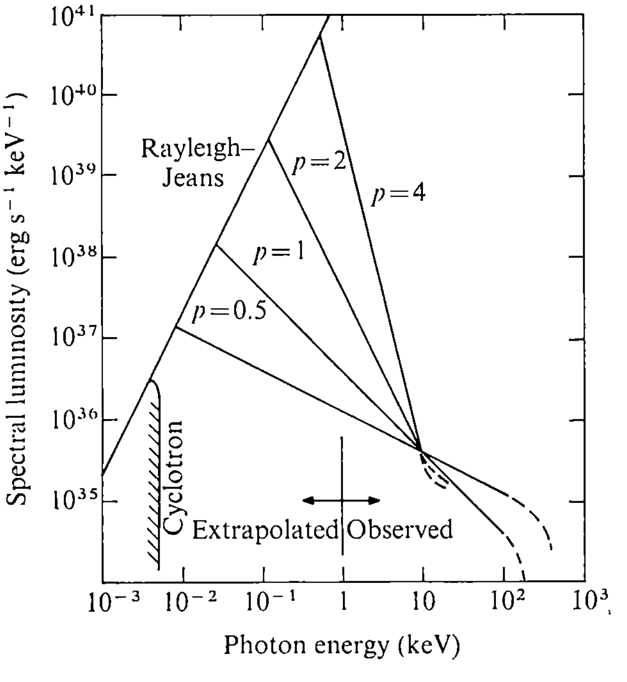
$$\mathrm{d}L/\mathrm{d}E \simeq \mathrm{d}L_s/\mathrm{d}E\,(E/E_s)^{-p};\; E_s \lesssim E \lesssim kT_e \qquad (2)$$

The electron distribution need not be precisely Maxwell-Boltzmann. The spectral index, p, is determined by the physical properties of the scattering cloud through the relation

$$p = -\frac{3}{2}+\left(\frac{9}{4}+\frac{4}{y}\right)^{1/2} \qquad (3)$$

where y is the "Comptonisation parameter", $y \equiv (4kT_e/m_ec^2)$. Max $(\tau_{es}, \tau_{es}{}^2)$ and τ_{es} is the electron scattering optical depth of the cloud. For $E \gtrsim kT_e$ (or, because of relativistic effects, $E \simeq$ 150 keV, whichever is less), the inverse Compton spectrum is no longer given by equation (2) and steepens roughly exponentially. The above spectrum applies as long as $y \lesssim 5$ (unsaturated "Comptonisation"), as long as the cloud acts as a single emitting region, and as long as inverse Compton scattering dominates other cooling mechanisms.

Fig. 1 X-ray energy spectrum $\mathrm{d}L/\mathrm{d}E$ of Cyg X-1. Observations show $\mathrm{d}L/\mathrm{d}E \propto E^{-p}$, $0.5 \lesssim p \lesssim 4$, for photon energy $E \gtrsim 0.5$ keV; these spectra we extrapolate down in E to their intersection with a Rayleigh–Jeans spectrum for $T = 10^9$ K. Also shown is a source spectrum for thermal cyclotron radiation.



For any total luminosity L dictated, for example, by the rate of gravitational energy release which is powering the X-ray source, and for any luminosity L_s of the soft photon source, the cloud will adjust its y (and p) so that $\int(\mathrm{d}L/\mathrm{d}E)\mathrm{d}E = L$. If the cloud is not emitting enough energy because its spectrum is too soft, the electrons will heat up, y will increase, and the spectrum will get harder; see equations (2) and (3). Changes in either L or L_s can induce a change in y and hence in p.

To interpret the observed spectrum and its variations, let us first extrapolate the observed spectrum to < 1 keV and consider that energy E_{RJ} where it intersects the Rayleigh–Jeans portion of a black body spectrum

$$\mathrm{d}L_{RJ}/\mathrm{d}E \simeq 2\times 10^{43}\,\mathrm{erg\,s^{-1}\,keV^{-1}}(T_e/10^9\,\mathrm{K})(E/10\,\mathrm{keV})^2$$

(see Fig. 1). Here we have adopted a radius ~ $30(GM_{\text{black hole}}/c^2) \simeq 300GM_\odot/c^2 \simeq 5\times 10^7$ cm for the emitting region, typical of most models of Cyg X-1 (a factor of three greater or smaller would make little difference to our results). The intersection is given by

$$\left(\frac{E_{RJ}}{10\,\mathrm{keV}}\right)^{2+p} \simeq 10^{-8}\left(\frac{T_e}{10^9\,\mathrm{K}}\right)^{-1}\left(\frac{d}{2.5\,\mathrm{kpc}}\right)^{2} \qquad (4)$$

Now, any incoherent soft photon source cannot be more luminous than a black body; therefore we must have $E_s \gtrsim E_{RJ}$ as a strict lower limit on E_s; in fact, most possible sources (see following discussion) will be optically thick below some characteristic photon energy E_s, so that $E_s \simeq E_{RJ}$.

In the low state, $p \simeq 0.5$ and therefore $y \simeq 2$. If $T_e \simeq 10^9$ K, then we learn that $\tau_{es} \simeq 1$ and equation (4) yields $E_{RJ} \simeq 0.01$ keV. Thermal cyclotron radiation is likely to be the soft photon source here. The detailed models[9,12] of Cyg X-1 predict $B \simeq 10^7$ gauss in equipartition, giving $E_{\text{cyclotron}} \simeq 10^{-4}$ keV, and we calculate (using $\tau_{es} \simeq 1$) that self-absorption occurs up to about the 50th harmonic. Thus $E_s \simeq 0.005$ keV, in tolerable agreement with $E_{RJ} \simeq 0.01$ keV. Therefore, we suggest that the reason the spectrum of Cyg X-1 is never flatter than $p \simeq 0.5$ is that thermal cyclotron radiation is always present as a minimal soft photon source with $E_s \simeq E_{RJ} \simeq 0.01$ keV and $L_s \simeq 10^{34}$ erg s^{-1}. Examination of Fig. 1 clearly indicates that additional soft photon sources must lead to steeper spectral slopes.

In the high state, $p \simeq 4$, $y \simeq 0.2$ and almost all of the luminosity emerges near the soft photon input energy E_s. Apparently, a new soft photon source is operating which produces nearly the entire observed luminosity of the source $L_s \simeq L \simeq 10^{38}$ erg s^{-1} and which thus requires only a marginal boost (low y) from inverse Compton scattering to balance the rate of gravitational energy release, L. As striking as the observed transitions in state are, we infer an even more spectacular change in the nature of the soft photon source, amounting to a change by a factor of ~ 10^4 in L_s.

At $p = 4$, equation (4) gives $E_{RJ} \simeq 0.5$ keV for $T_e \simeq 10^9$ K and even higher E_{RJ} for lower T_e. A plausible candidate for the soft photon source in the high state is a cool, optically-thick accretion disk within the optically thin scattering cloud, since the temperature of a black body of our adopted radius and emitting the observed luminosity of Cyg X-1 would be about 5×10^6 K. At the steepest slope, $p \simeq 4$, one should almost certainly see a peak and turnover in the power-law spectrum not far below 1 keV, since a continuation of such a power law much lower than 1 keV would constitute an intensity exceeding the black-body intensity for any reasonable temperature. The excess hard flux seen at $E \gtrsim 10$ keV must originate in a different region of the source or by a different mechanism, according to this view.

Neutron-capture cross sections for ^{186}Os and ^{187}Os and the age of the Universe

WE have measured the neutron-capture cross sections for ^{186}Os and ^{187}Os in the energy range up to 150 keV, corresponding to stellar temperatures up to $\sim 18\times10^8$ K. The knowledge of these cross sections enables us to calibrate the $^{187}\text{Re}\rightarrow{}^{187}\text{Os}$ nuclear β-decay clock and thus to make a new radiogenic determination of the age of the Universe.

There are several techniques used by astrophysicists to determine the age of the Universe. These include the use of measurements of the expansion of the universe[1] (Hubble constant) and of observations of stars in globular clusters[2] as well as nucleosynthetic techniques. All of the techniques involving nucleosynthesis used to date, however, have been based on the theory of the *r*-process for the formation of the elements[3]. The *r*-process involves neutron capture on a rapid time scale in supernova events. It follows a path off the line of β stability and is responsible for the formation of all of the elements heavier than bismuth. By calculating the production ratios for various *r*-process nuclei such as ^{232}Th, ^{235}U and ^{238}U in supernova events and by measuring the current abundance ratios of the same nuclei, it is possible to arrive at a chronology of supernova events (and hence at the age of the Universe) This is the basis of the U–Th dating technique of Fowler and Hoyle[4].

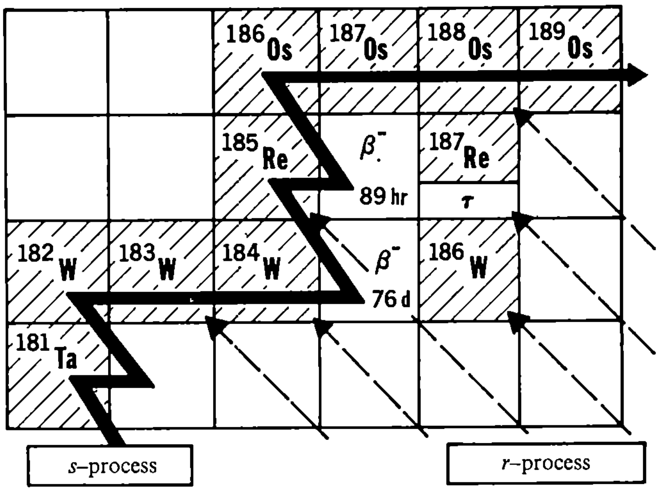

Fig. 1 The *s*-process (heavy line) and *r*-process (dashed line) paths in the vicinity of the Os isotopes. The shaded boxes represent stable nuclei except for ^{187}Re ($\tau_{1/2} = 44\times10^9$ yr). ^{186}Os and ^{187}Os are shielded from the *r*-process by ^{186}W and ^{187}Re, respectively.

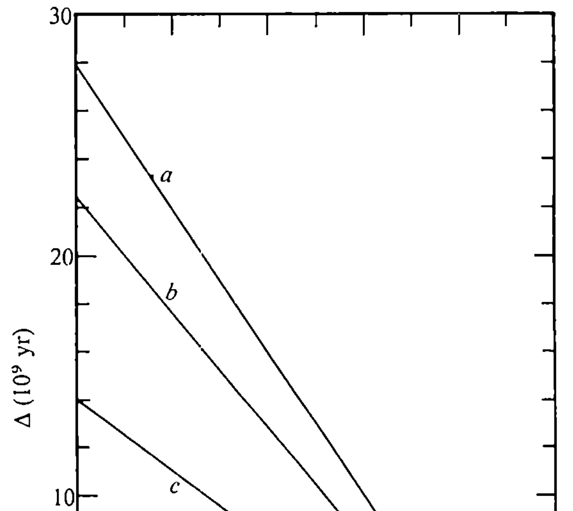
In 1964, Clayton[5] suggested the use of a process which does not depend critically upon a knowledge of the *r*-process production rates. Rather it depends mainly upon the *s*-process, which rests upon a more firm theoretical footing. The *s*-process refers to neutron capture on a much slower time scale than the *r*-process, and it follows essentially the line of β stability. Clayton's suggestion involves the β decay of ^{187}Re to ^{187}Os, which has a half-life of $\sim 44\times10^9$ yr and which therefore is much longer than estimates of the age of the Universe obtained from the above mentioned dating techniques ((10–15) × 10^9 yr). Figure 1 shows a portion of the chart of the nuclides in the vicinity of the Re and Os isotopes. Both the *s*-process and the *r*-process paths are shown. It can be seen that ^{187}Re is an *r*-process nucleus, while both ^{186}Os and ^{187}Os are shielded from the *r*-process and hence their synthesis initially involves only the *s*-process. If we denote the *s*-process abundances of ^{186}Os and ^{187}Os as N_s^{186} and N_s^{187} and the radiogenic component of ^{187}Os

Fig. 2 The duration of nucleosynthesis Δ, before Solar System condensation as a function of the Maxwellian-averaged laboratory neutron-capture cross section ratio for ^{186}Os and ^{187}Os. The three (of the several possible) models for the supernova rate that are shown (*a*, uniform; *b*, exponential and *c*, sudden) are discussed in the text.



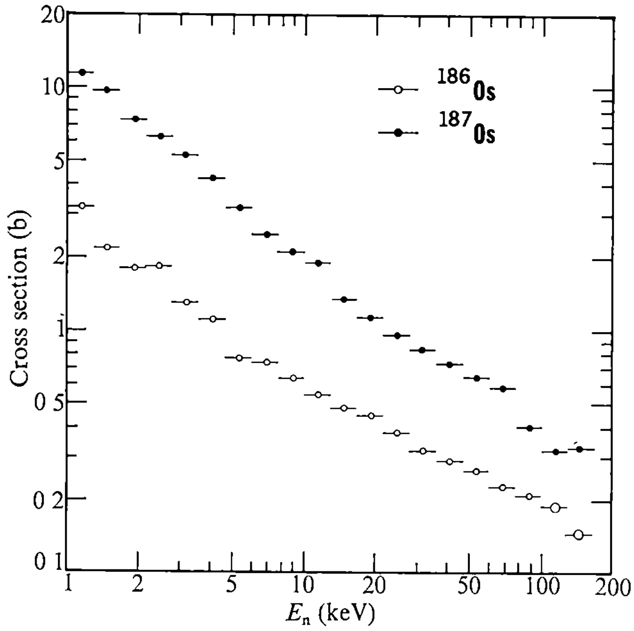


Fig. 3 The neutron-capture cross sections against laboratory neutron energy for ^{186}Os (○) and ^{187}Os (●). The horizontal bar represents the size of the energy bin into which the data have been averaged. (The energy resolution of the actual measurement was much better.) The uncertainty for each data point lies within the plotted symbol and typically is 5% at 30 keV.

resulting from the ^{187}Re β decay as N_{rad}^{187}, then the total abundances can be written as

$$N^{186} = N_s^{186}$$
$$N^{187} = N_s^{187} + N_{\text{rad}}^{187} \qquad (1)$$

One of the assumptions of the *s*-process is that $N\bar{\sigma}$ is constant for adjacent *s*-process nuclei, where $\bar{\sigma}$ refers to the Maxwellian-averaged neutron-capture cross section for a temperature appropriate to the site of the *s*-process ($kT \simeq 30$ keV). This assumption has been justified by Macklin *et al.*[6] for the tin, samarium, strontium, and zirconium isotopes. Using this result and equation (1), it is possible to write the ratio of the radiogenic component of ^{187}Os to its parent ^{187}Re abundance N_{Re}^{187} as

$$\frac{N_{\text{rad}}^{187}}{N_{\text{Re}}^{187}} = \frac{(N^{187}/N_{\text{Os}}) - f(\bar{\sigma}_{186}/\bar{\sigma}_{187})_{\text{LAB}}(N^{186}/N_{\text{Os}})}{N_{\text{Re}}^{187}/N_{\text{Re}}}\left(\frac{N_{\text{Os}}}{N_{\text{Re}}}\right) \qquad (2)$$

where N_{Os} and N_{Re} refer to the elemental abundances of Os and Re. The measured laboratory cross-section ratio $(\bar{\sigma}_{186}/\bar{\sigma}_{187})_{\text{LAB}}$ must be multiplied by the factor f since the Os nuclei in a stellar environment exist in excited states as well as the ground state. The most probable value for this factor has been calculated by Woosley and Fowler (personal communication) to be $f = 0.83$. The values used for the other parameters in equation (2) are listed in Table 1.

Table 1 Values used in equation (2) to compute $N_{\text{rad}}^{187}/N_{\text{Re}}^{187}$

N^{187}/N_{Os}	0.0123 ± 0.0006
N^{186}/N_{Os}	0.0159*
$N_{\text{Re}}^{187}/N_{\text{Re}}$	0.65*
$N_{\text{Os}}/N_{\text{Re}}$	12 ± 1.2

These values are averages of results obtained by geochemical methods, referred to the time of solar system condensation, using $\tau_{1/2} = 44 \times 10^9$ yr from ref. 7.
*The geochemical uncertainties for these quantities are negligible.

Clayton[5] used a simple model to determine the above ratio as a function of the time and duration of nucleosynthesis. He assumed that *r*-process nucleosyntheis (which formed ^{187}Re) began at a time Δ before the condensation of the Solar System and decreased exponentially at a rate λ_A. Therefore λ_A is a measure of the supernova rate in the Galaxy. If λ_B denotes the β-decay rate of ^{187}Re, one can express the ratio $N_{\text{rad}}^{187}/N_{\text{Re}}^{187}$ at the time of Solar System condensation, using the Bateman equations for radioactive growth and decay, as

$$\frac{N_{\text{rad}}^{187}}{N_{\text{Re}}^{187}} = \left\{\frac{\lambda_A - \lambda_B}{\lambda_A}\exp(\lambda_B\Delta)\frac{1-\exp(-\lambda_A\Delta)}{1-\exp[-(\lambda_A-\lambda_B)\Delta]}\right\} - 1 \qquad (3)$$

The two extreme cases of this model are (1) sudden synthesis (a single supernova event), for which $\lambda_A \to \infty$ and equation (3) becomes $N_{\text{rad}}^{187}/N_{\text{Re}}^{187} \simeq \lambda_B\Delta$, and (2) uniform synthesis (a constant rate of supernova events), for which $\lambda_A \to 0$ and equation (3) becomes

$$N_{\text{rad}}^{187}/N_{\text{Re}}^{187} \simeq \lambda_B\Delta/2$$

It should be noted that not only does case (1) result in the minimum value for Δ, but this value also is the average value for Δ, irrespective of the rate (or the rate of change) of supernova events, and hence independent of the model used for the time history of the stellar burning process.

If we now plot Δ as a function of $(\bar{\sigma}_{186}/\bar{\sigma}_{187})_{\text{LAB}}$ using equations (2) and (3) we obtain the curves shown in Fig. 2. The two extreme cases mentioned above are plotted along with an intermediate case where the supernova rate is assumed to be exponential in time, with its activity at Solar System condensation equal to $1/e$ of its initial value ($\lambda_A = 1/\Delta$). For the curves in Fig. 2, the β-decay half-life measurement of Herr *et al.*[7] ($\tau_{1/2} = 44 \times 10^9$ yr) was used for λ_B.

The purpose of our measurement therefore was to determine the ratio of the neutron-capture cross sections for ^{186}Os and ^{187}Os, Maxwellian averaged for $kT = 30$ keV, from which $N_{\text{rad}}^{187}/N_{\text{Re}}^{187}$ can be obtained using equation (2). From this ratio, the duration of nucleosynthesis (Δ), and hence the age of the Universe, can be obtained as discussed above. This measurement was performed using the neutron time-of-flight facility at the Livermore 100-MeV electron linac. Details of the experimental techniques used for these neutron-capture cross-section measurements are given in ref. 8. For the present experiment, the neutron-capture cross sections for ^{186}Os and ^{187}Os were measured over the neutron-energy interval from 2 eV to 150 keV, using a 3.278-g powdered-metal osmium sample enriched to 78% isotopic purity of ^{186}Os and a similar 2.959-g sample enriched to 71% isotopic purity of ^{187}Os. Since the impurities consisted of the other stable Os isotopes, the neutron-capture cross sections for all these isotopes were measured as well. The data were reduced to absolute cross sections by including a ^{165}Ho sample in the measurement and normalising to the measured ^{165}Ho(n,γ) cross section[9]. The resulting average neutron-capture cross sections obtained for ^{186}Os and ^{187}Os are shown in Fig. 3. These cross sections were Maxwellian averaged for $kT = 30$ keV, from which the value for $(\bar{\sigma}_{186}/\bar{\sigma}_{187})_{\text{LAB}} = 0.39 \pm 0.03$ was obtained. The uncertainty in this ratio includes systematic as well as statistical uncertainties in the measurement. Finally, the value obtained for $(\bar{\sigma}_{186}/\bar{\sigma}_{187})_{\text{LAB}}$ is only weakly dependent upon the choice of kT near 30 keV.

This measurement of $\bar{\sigma}_{186}/\bar{\sigma}_{187}$ therefore removes the major unknown in equations (2) and (3) that prevented, until now, the determination of the age of the Universe by the Re → Os clock. From Fig. 2, a value for $\Delta = (12.9 \pm 3) \times 10^9$ yr is obtained using the above value for the cross section ratio for the exponential case. (This 23% uncertainty results from the 8% uncertainty for the present measurement together with the uncertainties in the other quantities in equation (2).) This value can be compared directly with the U–Th dating method[4], which yielded $\Delta = (7 \pm 2) \times 10^9$ yr using the same exponential description.

Thus there is a substantial discrepancy between the results of the two dating techniques.

It should be pointed out that the Re → Os dating technique depends strongly on an accurate determination of λ_B ($= 1/\tau_B$). At the present time, the best two measurements[7,10] of this half life disagree by 50%. We have chosen to use the measurement of Herr *et al.*[7] in our determination of Δ. Since the value of τ_B from ref. 10 is much larger than that reported in ref. 7, the discrepancy between the present result for Δ and that obtained from the U–Th method would be increased considerably if the value for τ_B from ref. 10 were used. There are other uncertainties involved in the Re → Os method, some of which are discussed in detail by Clayton[5]. Another is the possibility that some of the ^{187}Re, and hence some of the radiogenic ^{187}Os, is produced by the *s*-process. These uncertainties involve, however, effects that are either not well understood or of a speculative nature; therefore they will not be discussed further here.

If, then, we assume that the time between the end of nucleosynthesis in the Galaxy and the present time is 4.7×10^9 yr, we obtain the age of the Galaxy to be $\Delta + 4.7 = 17.6$ (in units of 10^9 yr). The time between the beginning of the Universe and the formation of the Galaxy is not known, but current estimates[11] give $\sim 2 \times 10^9$ yr. Therefore the Re→Os dating method, based on the results reported here, indicates that the age of the Universe is $\sim 19.6 \times 10^9$ yr (and the uncertainty in this number probably is no greater than 4×10^9 yr). The present results thus yield an age which is greater than other recent estimates of this age, from the expansion of the Universe ($(16.6 \pm 1.7) \times 10^9$ yr, ref. 12), from globular clusters ($(13 \pm 3) \times 10^9$ yr), and from the U–Th method ($(14 \pm 3) \times 10^9$ yr).

This work was carried out under the auspices of the US ERDA.

Gravity signature of fossil plate boundaries in the Canadian Shield

The Canadian Shield is a mosaic of structural provinces, each with characteristic internal structural trends and styles of folding[1]. Boundaries between provinces have been delineated where trends are truncated along unconformities or along orogenic fronts. The validity of this subdivision of the shield has been supported by isotopic dating of orogenies[2]. Thus, the Superior province is the type region for the Kenoran Orogeny (2,560 Myr BP), and the Churchill and Grenville provinces are the type regions for the Hudsonian (1,800 Myr) and Grenvillian (1,000 Myr) orogenies, respectively.

Gravity signatures observed across structural province boundaries in five different areas are remarkably similar (Figs 1 and 2*a*). We suggest here that they originate from essentially identical crustal structures formed in response to fundamental processes operating during Precambrian episodes of cratonic convergence, collision and suturing. Three geosutures have so far been identified at or near structural province boundaries in the shield. The suture peripheral to the Superior Craton is the most easily recognised[3–5] because it is characterised by distinctive Aphebian (Lower Proterozoic) geosynclinal and oceanic sedimentary, volcanic, and ultramafic rocks, or their metamorphosed equivalents. The interpretation of these rocks as a suture therefore depends on the juxtaposition of pseudo-ophiolites typical of the plate accretion environment and geosynclinal sediments typical of zones of plate consumption[4]. The suture extends for some 3,200 km from the Manitoba nickel belt (Nelson Front) through the Split Lake–Fox River region of Manitoba and the Hudson Bay Lowlands of northern Ontario to eastern Hudson Bay and thence to the Cape Smith Belt and Labrador Trough of northern Quebec (Fig. 1). Reactivated basement of the Churchill Province is sharply separated by the suture rocks from the non-reactivated Superior Craton in Manitoba, Ungava and Quebec–Labrador[6,7]. Interpretations of large amplitude Bouguer anomalies associated with the Cape Smith Belt[8] and Labrador Trough[7,8] indicate that the cratons

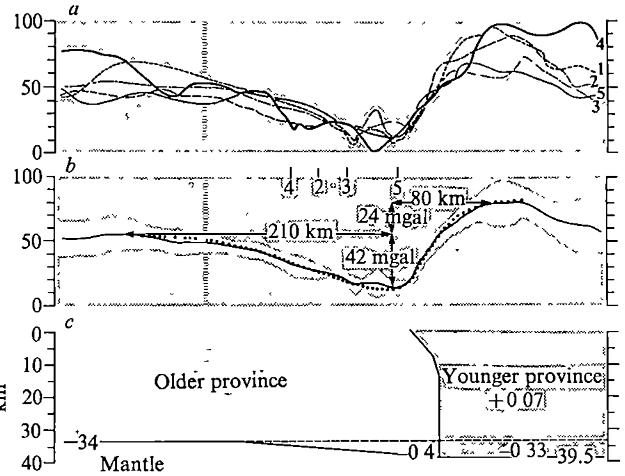
Density contrasts in g cm^{-3}; depths in km



separated by the suture have different crustal densities and thicknesses.

Interpretations of palaeomagnetic data[9-11] suggest that part of the Grenville Province broke away from the remainder of the shield 1,250 Myr ago, and then rejoined it about 1,000 Myr ago. These events require that a suture also exists within the Grenville Province. Different locations have been suggested for such a suture[11-13]. Most recently, Thomas and Tanner[14] have suggested that the suture lies up to 100 km inside the Grenville Province, south of a zone believed to contain reworked rocks of the older adjacent provinces lying to the south of the Grenville Front[11]. This location is based on the interpretation of gravity anomalies along the front as an edge-effect between juxtaposed crustal blocks of different mean density and thickness[8,14,15]. The boundary between the blocks is the suture. It is cryptic in the sense that no clear surface indications of a suture have yet been recognised. Petrological investigations indicate, however, that rocks at present at the surface in this region were formed at temperatures of 700–750 °C, and at depths of about 20 km (ref. 12). At these crustal levels, ultramylonites and pseudotachylites are likely to be the only indicators of the line of suturing[6].

A third suture has been postulated at or near the metamorphic boundary between the Slave and Churchill provinces[16,17]; it is known as the Thelon Front[18]. Belts of cataclastic gneiss and mylonite occur roughly parallel with the front inside the Churchill Province[19]. The front is bounded on either side by coextensive negative (Slave) and positive (Churchill) acurate gravity anomalies (Fig. 1) which have also been interpreted as an edge-effect between juxtaposed crustal blocks of different mean density and thickness. According to this interpretation[17] the density discontinuity penetrates the crust and represents a cryptic suture between collided cratons. The gravity anomaly is almost identical to those found at the western extension of the Cape Smith Belt, the Labrador Trough, and the Grenville Front.

Bouguer anomaly profiles numbered 1–5 across these boundaries (Fig. 1) are shown on a common datum in Fig. 2*a*. Apart from short wavelength anomalies attributable to local geological features, all five profiles are remarkably similar. In each case the gravity profile decreases gradually from a background level over the older province to a minimum near the inter-province boundary zone, and then increases sharply to a broad maximum over the younger province, some 16 to 40 mgal higher than over the older province. The smoothed gravity signature, which we call the type anomaly, derived by averaging profiles 1 to 5, is shown in Fig. 2*b* within an envelope which varies according to the standard deviation calculated at intervals of 5 km along the profiles. If the anomaly over the older province is regarded as background, the amplitudes of the minimum and the maximum are −42 mgal and 24 mgal, respectively. The average gradients over the older and younger province margins are about 0.2 mgal km^{-1} and 0.8 mgal km^{-1}, respectively. Near the minimum, the gradient is much steeper (up to 1.8 mgal km^{-1}) over the younger province.

A type crustal model has been derived from the type anomaly; it is constrained in three ways. Seismic results[20,21] suggest that the crust underlying both the Superior and Slave provinces is about 34 km thick in the vicinity of the profiles. This thickness was assigned to the crust of the older province along with an assumed normal crustal density of 2.84 g cm^{-3}. The density of the upper mantle was assumed to be 3.24 g cm^{-3}. Keeping these parameters fixed the thickness and density of the younger crustal block were varied until the calculated anomaly matched the type anomaly. The crustal model is shown in Fig. 2*c*, and the computed anomaly in Fig. 2*b*. The crustal thickness of the younger province is 39.5 km, and the density is 2.91 g cm^{-3}. The density discontinuity dips towards the younger province from a point 13 km from the minimum, to a depth of 14 km at a distance of 35 km from the minimum, where it becomes vertical over the rest of its length. The base of the crust of the older province dips gently towards the contact over a distance of 160 km. This non-isostatic crust is required to fit the gravity minimum. The blocks are otherwise in approximate isostatic equilibrium.

The model indicates that the younger crustal block is consistently thicker and slightly denser than the older. This consistency is surprising, but all the more surprising because not only do the structures have a wide geographic distribution but they are also of vastly different ages. This suggests that similar processes have operated throughout much of Precambrian time. The density discontinuity of the type model penetrates the whole crust and separates cratons of different density, thickness, age and internal structure; it is interpreted as a vestigial suture between collided continental blocks. The model with slight modifications to crustal density and thickness can be applied to all five boundary zones and may apply to other examples in Canada and elsewhere wherever the gravity signature of the type model is recognised.

Dating of historical earthquakes by mud profiles of lake-bottom sediments

RECENTLY, Ben-Menahem *et al.*[1] derived tectonic patterns and slip rates in the Jordan Rift Valley by combining a comprehensive study of seismological, historical, geological and morphological data. It was found that the principal seismic activity along the Jordan Valley is due to a left-lateral strike-slip fault, striking 11° east of north and extending for about 50 km from 32°N to 31°30′N along the 35°30′ meridian. Its most active part in the past four millenia has been near the monastery of John the Baptist which, according to tradition, is the place where the Israelites crossed the Jordan and where Jesus was baptised. The fault trace and its role in the historical seismicity of the area is shown in Fig. 1. It has an estimated mean rate of activity of 2–3 events per century at magnitudes from 5 to 7 (ref. 1) An aseismic slip rate of at least 3 mm yr^{-1} is taking place along this fault[1]. Here we show how this activity is reflected in an unusual limnological process which takes place at the bottom of the Dead Sea and which can serve as a 'geophysical clock' to date historical events.

The fault's seismicity has been reflected in many historical records, in particular the Bible, in which we find distant echoes of tectonic events as remote as 2000 BC. Lists of earthquakes have been compiled from many and diverse sources (see, for example, refs 2–5), and a new revised list,

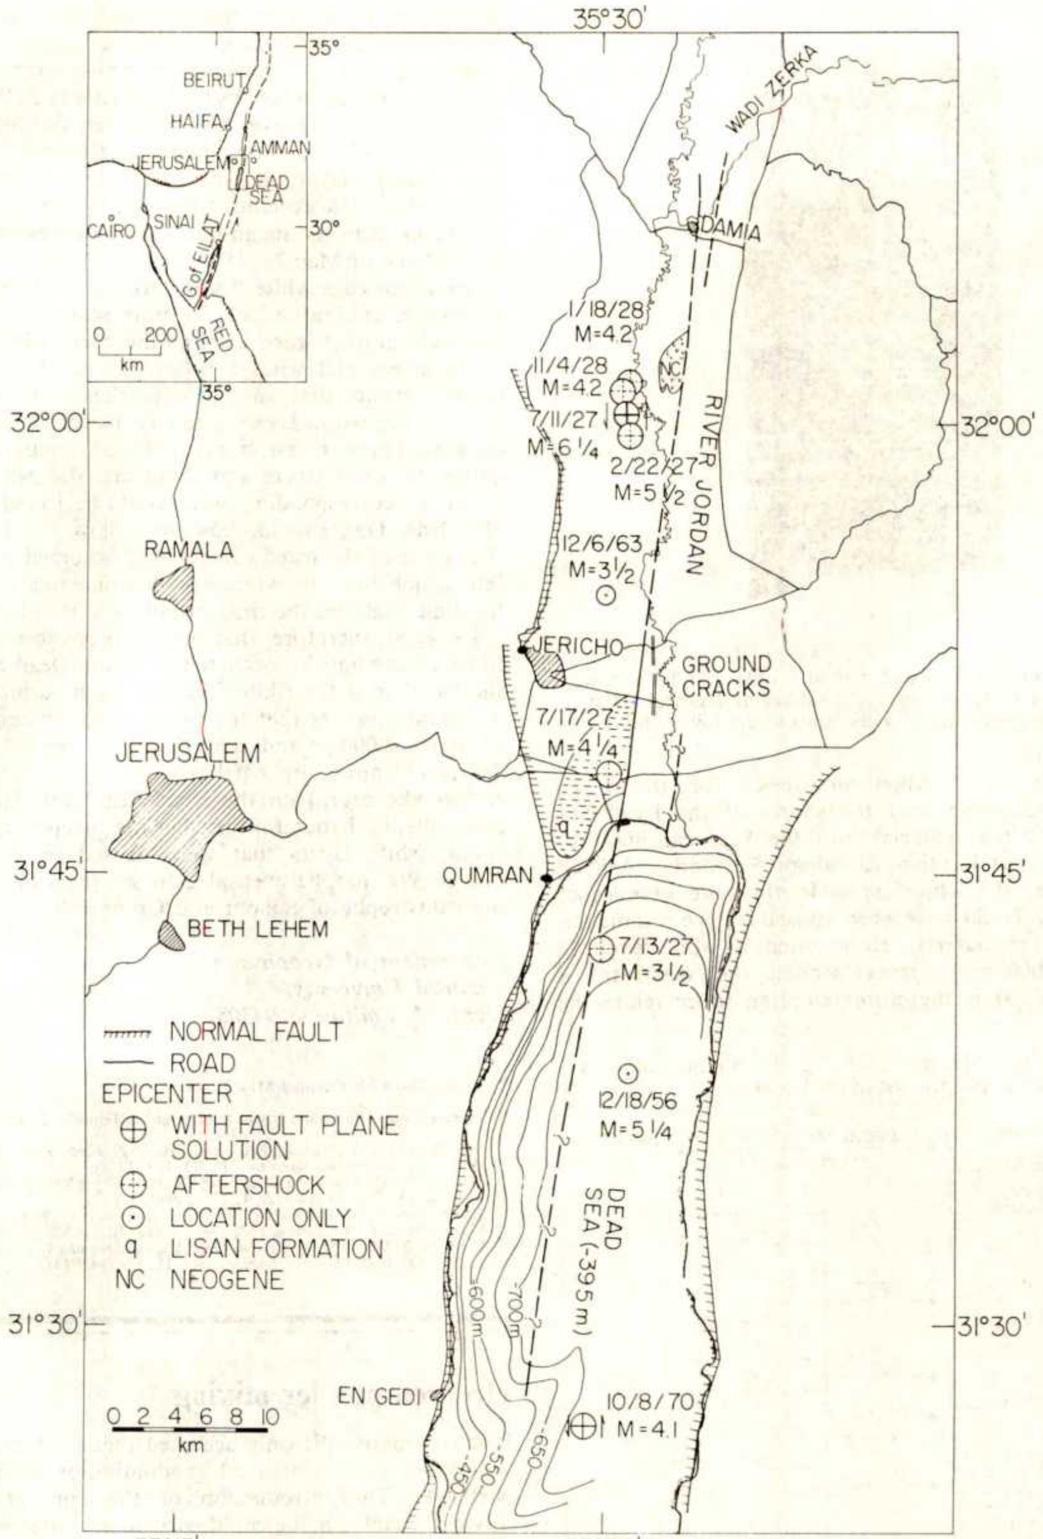

Fig. 1 Map of the Dead Sea fault (see ref. 1).

which is believed to include seismic events above a Richter magnitude 5, is given in ref. 1.

That list, although inaccurate and incomplete in detail, probably includes the major seismic events that have taken place around the Dead Sea fault during the past 4,000 yr. Although many of the epicentres are known with poor accuracy, the list suggests that the number of intermediate and major earthquakes in the area (M=5–7) was about 50 in the past 2,000 yr, yielding an average 'quiet' interval of 40 yr. We have used observations of Elazari-Volcani[6] who obtained a number of profiles of mud samples from depths of 70–330 m at different places in the Dead Sea during December 1941. At one place about 6 km south-west of the northern shore, a profile 170 cm long was obtained from a depth of 100 m. On dissecting the profile longitudinally, a 'spectrum of layers' of different colours—black, dark-blue, grey brown and white—was revealed (Fig. 2). The zones of sedimentation, distinctly seen, form no seasonal repeat pattern, as do, for example, the annual rings of trees. Similar observations were reported for many other lakes by Perfiliev[7].

On September 10, 1943, an earthquake was felt along the Jordan Valley. Macroseismic evidence placed the epicentre at the northern tip of the Dead Sea fault, with an estimated

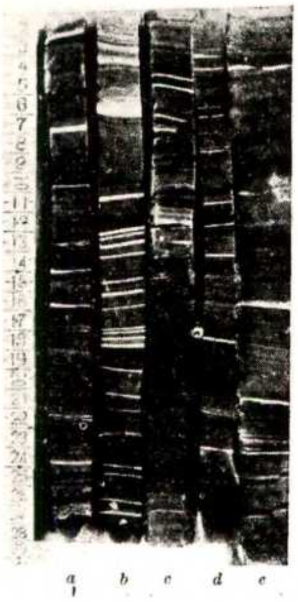

Fig. 2 'Spectrum' of layers of a mud profile of 170 cm long obtained from the bottom of the Dead Sea at depth of 100 m. Section starts at upper end of *a* and ends at the lower end of *e*.

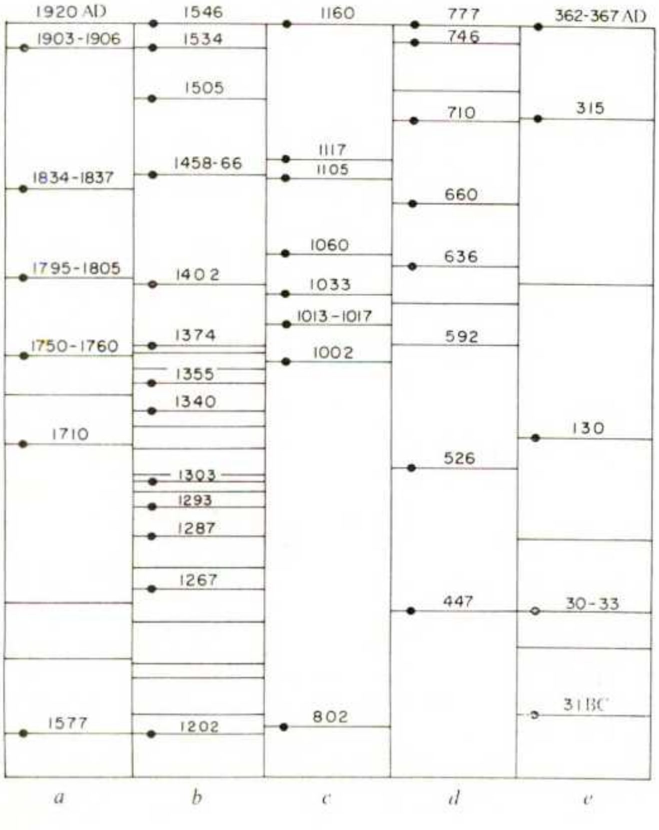
Richter magnitude of 5. About one week before this event, new springs opened up near the shores of the Dead Sea and disgorged white material into the Sea, causing prolonged whitish discoloration for about 5 months. Ashbel[8] conjectured that the white layers in the core samples of Elazari-Volcani[6] could have been caused by the sedimentation of that white material. He counted 50 white layers in the total of 2,000 yearly layers seen in the 'spectrum' of Elazari-Volcani[6]. It is therefore tempting to correlate the time intervals of our chronological list with the length intervals of the white layers in Fig. 2.

Fig. 3 Dating of white layers of Fig. 2 with the aid of a chronological list of earthquakes.



Starting with the conspicuous white layer in the upper part of a column *a* (opposite the numbers 2/3) we associate it with two earthquakes that occurred during this century on the Dead Sea fault (1903, 1906; see ref. 1). The next white layer is in the same column opposite the numbers 7/8. Assuming that the thickness of the layer is proportional to the magnitude, this could correspond to the great shock of May 23, 1834 ($M=6.25$) which is also known to have caused a white discoloration of the Dead Sea. This permits a 'calibration' of the time scale in Fig. 2 (18.5 yr per scale unit). Figure 3 shows the correlation between the white layers and what I believe to be the corresponding seismic events that gave rise to these layers. All in all, 65% of the white layers could be matched to listed earthquakes. There is an uncertainty of about 10 yr in the dating of some layers and there are also white layers for which no corresponding event could be found in the available lists. One should, however, allow for the possibility that some of the listed earthquakes occurred away from the fault, such that the white discoloration was faint, and that the time scale on the mud profile was not always linear.

I suggest, therefore, that there is a possible correlation of times of earthquake occurrence on the Dead Sea fault and the location of the white layers in the mud profile. There is no doubt however that the mud sample represents a period of about 2,000 yr and that the white layers *in toto* were definitely caused by earthquakes (or by accelerated pre-earthquake creep) on the Dead Sea fault during the past two millenia. I therefore predict that deeper mud cores will reveal white layers that were caused by earlier seismic events. We may be even able to see the white signature of the catastrophe of Sodom and Gomorrah.

Ordered powder mixing

Until recently, the only accepted theory of powder mixing was based on a statistical randomisation of non-cohesive particles[1]. The introduction of the concept of ordered mixing[2] enables a logical theory to be established for the mixing of small cohesive particles to a considerable degree of homogeneity. The concept of ordered mixing has attracted considerable support[3–5]. A basic principle of ordered mixing is that fine particles will adhere, especially to larger particles. The adhesional forces involved may be electrostatic or surface tensional. For a homogeneous system to be formed, the weight of fine particles adhering to unit surface area of the larger particles should be constant. We report here such a condition in the mixing of a fluid energy milled closely sized fraction (2.6 μm) of salicylic acid with a multi-sized distribution of sucrose crystals, in the ratio 1 : 1,000 by weight.

The powders were mixed in a Revolvo-Cube rotating cube mixer for 6 h. The sucrose crystals were then classified by sieving. The collected fractions were each dissolved in 50%

Table 1 Ordered mixing of microfine salicylic acid with coarse sucrose crystals

Mean size fraction sucrose crystals (μm)	Weight of fraction (%)	Weight of salicylic acid/unit weight of sucrose ($\times 10^{-4}$)	Weight of salicylic acid/unit surface area of sucrose (10^{-7} g cm^{-2})	Surface area of sucrose coated (%)

ethanol and assayed for salicylic acid content. The results are given in Table 1.

Over the range of particle size, the weight of salicylic acid per unit surface area of sucrose crystals (assuming cubic crystals, as observed microscopically) is constant within the range of experimental error. From the projected area of the fine particles, it is possible to calculate that ~2.5% of the area of the larger sucrose particles is coated with fine particles at this level of mix dilution.

Segregation was not observed during the classification operation, as demonstrated by the lack of material passing through the finest sieve used.

These results demonstrate the possibility of ordered mixing processes for producing highly homogeneous mixtures of powdered materials. The application of this process to a wide number of different industrial uses is anticipated.

Aluminium-26 in a manganese nodule

MANGANESE nodules are generally considered to have accumulated very slowly. Radiometric studies by ^{230}Th, ^{231}Pa, and ^{234}U/^{238}U suggest their growth rates to be a few mm per 10^6 yr (refs 1–3). This leads to an enigma: how do they escape from burial by associated marine sediments which are accumulating three orders of magnitude faster than the nodules? Though this problem remains open, the postulated slow growth rates might permit manganese nodules to accumulate in a small volume high concentrations of long lived cosmogenic radionuclides ^{10}Be ($\tau_{\frac{1}{2}} = 1.5$ Myr) and ^{26}Al ($\tau_{\frac{1}{2}} = 0.715$ Myr) which were formed through the bombardment of atmospheric constituents by galactic cosmic rays. Indeed, Somayajulu[4] and Krishnaswami *et al.*[5] have found that three manganese nodules from the Pacific basin concentrate considerable activities of ^{10}Be at their surface (9–68 d.p.m. kg^{-1}). These concentrations are several times higher than those found in pelagic sediments. We report here on a search for ^{26}Al in manganese nodules.

The TECHNO-1 manganese nodule, obtained by a dredge at a depth of 4,020 m at the north of Tuamotu archipelago has a crust ~ 1,000 cm^2 in area and ~ 3 cm thick. This crust covers a base of phillipsite. Half of the crust (425 cm^2) was provided for the present study. The crust was sliced horizontally into four sections: section I (0–2.3 mm), section II (2.3–8 mm), section III (8–14 mm), and section IV (14–23 mm).

For the analysis of ^{26}Al, the nodule material was leached twice in hot, 6 N HCl. After being isolated by centrifugation, the insoluble phases were completely dissolved in HF and the HCl-leached fraction and the HF-dissolved fraction were treated separately for further purification. Aluminium was precipitated with ammonium hydroxide, and iron, manganese and thorium were removed by the dissolution of aluminium hydroxide with NaOH. This purification process was repeated three more times, each time with the addition of a solution of Fe carrier which serves as scavenger for Th. The purified Al was finally converted to Al_2O_3 and counted. In our study, the HCl fraction and the HF fractions were counted together. The chemical yield of Al was 65 ± 5%. The Al content of the nodule was 2%.

^{26}Al decays mostly by the emission of a positron followed by a 1.83-MeV γ ray. The positron thermalises and produces two 0.511-MeV γ rays, enabling the concentration of ^{26}Al to be measured by the coincident detection of a 0.511-MeV γ ray in one counter, and the sum peak of the other two γ rays (total 2.34 MeV) in another. The measurements were carried out with a low-level $\gamma - \gamma$ coincidence spectrometer which consists of two semi-cylindrical NaI (Tl) scintillators 30×25 cm. The same spectrometer was previously used for our measurements of ^{26}Al in marine sediments[6]. The samples from the manganese nodule were counted for 30,000–60,000 min and the background, for 60,000 min. The background count rate was 0.0137 ± 0.0005 c.p.m. The counting efficiency for ^{26}Al was 5.3 ± 0.3%.

^{26}Al was detected in the first section, where its concentration of 0.29 ± 0.14 d.p.m. kg^{-1} (a net count rate of $15 \pm 7 \times 10^{-4}$ c.p.m.) was higher than that found in a Pacific sediment: by our measurement, 0.081 ± 0.046 d.p.m. kg^{-1} (ref. 6). Therefore the postulated concentration of long lived cosmonuclides in manganese nodule is also confirmed for ^{26}Al.

The enrichment of ^{26}Al in manganese nodule relative to that

SCIENCE COLLEGE

in sediment is more evident when the specific activities (d.p.m. ^{26}Al per kg Al) are compared: 15±7 d.p.m. per kg Al in the manganese nodule and 0.9±0.5 d.p.m. per kg Al in the sediment. This indicates that cosmogenic ^{26}Al precipitates from seawater for preference with oxides, hydroxides and/or authigenic aluminosilicates rather than with detrital silicate minerals.

Measurements of ^{26}Al and ^{10}Be in a Pacific sediment[6] showed that the ^{26}Al:^{10}Be ratio in the sediment, 0.109±0.012, is in good agreement with the theoretical production ratio of 0.013±0.006 as well as with that measured in Greenland ice by McCorkell *et al.*[7], 0.017±0.008. From this theoretical ratio and the measured ^{26}Al activity in the nodule, we estimated the ^{10}Be activity in the 0–2.3-mm section of TECHNO-1 to be 22±15 ^{10}Be d.p.m. kg^{-1}. This estimated activity is compatible to the ^{10}Be activities measured by Krishnaswami *et al.* in three manganese nodules: 17, 32, and 89 d.p.m. kg^{-1} (these values are calculated for the 0–2.3 section from their measurements of the extrapolated activity at the surface, N_0, and the depth L at which the activity becomes N_0/e, by using the equation

$$C_x = LN_0\,(1-\exp(-X/L))/X$$

where C_x is the concentration at O–X cm section). The agreement suggests that the ^{26}Al:^{10}Be ratio in manganese nodules is of the same order as that in sediments, which is expected from the similarity of the geochemical behaviours of the two nuclides in seawaters.

If we assume that the ^{26}Al content decreases exponentially as a function of depth in the TECHNO-1 manganese nodule and that the decrease of ^{26}Al arises from the postulated slow growth rate of nodule material (1–5 mm per 10^6 yr), then it is possible to estimate the ^{26}Al content in the 2.3–23-mm section from the measured content of ^{26}Al in the 0–2.3-mm section (0.29±0.14 d.p.m. kg^{-1}). Concentrations of 0.004±0.002, 0.06±0.03, and 0.11±0.05 d.p.m. kg^{-1} are calculated for growth rates of 1, 5 and 10 mm per 10^6 yr respectively. The observed net count rate of $1(\pm 9)\times 10^{-4}$ c.p.m. gives 0.003±0.024 d.p.m. kg^{-1}. The upper limit of the observations for the 2.3–23-mm section, 0.03 d.p.m. kg^{-1}, is therefore compatible with growth rates of 1–5 mm per 10^6 yr.

As a solution to the enigma of the non-burial of manganese nodules by sediments, Arrhenius[8] and Lalou and Brichet[9] hypothesised that the radionuclides of interest were not incorporated in the nodule matrix during its growth, but were adsorbed later. The present results for ^{26}Al are not necessarily incompatible with such a hypothesis, because most of the ^{26}Al is found only in the first few millimetres section, but the precision of the present measurements limits further discussions.

We thank Professor J. Labeyrie and Drs C. Lalou and Teh-Lung Ku for their helpful discussion and also Dr D'Ozouville of CNEXO for providing the sample of the manganese nodule.

Reactions of $O(2^1D_2)$ with chlorofluoromethanes and CCl_4

UPPER atmosphere reactions involving chlorofluoromethanes are of considerable current interest[1-6]. It has been suggested that the diffusion of chlorofluoromethanes, from the troposphere into the stratosphere, where photochemical and reaction processes produce free chlorine atoms, could lead eventually to a depletion of ozone in the upper atmosphere[1,2], by way of the ClO_x cycle

$$Cl+O_3 \rightarrow ClO+O_2 \qquad (1)$$

$$ClO+O \rightarrow Cl+O_2 \qquad (2)$$

The work presented here was directed towards obtaining a more detailed understanding of the primary and secondary processes which take place in the photochemically initiated reaction between O_3 and the chlorofluoromethanes.

The reaction of $O(2^1D_2)$ with Freons 11–13 ($CFCl_3$, CF_2Cl_2 and CF_3Cl) is known to give rise to ClO radicals[6]

$$O(^1D)+CF_xCl_y \rightarrow ClO+CF_xCl_{y-1} \qquad (3)$$

and thus provides a means of direct entry into the ClO_x cycle. A number of other channels may, however, contribute to the overall rate of removal of $O(^1D)$, including quenching to the ground state, $O(^3P)$. Little is known about the importance of these other channels, or of the subsequent reactions of the CF_xCl_{y-1} radicals which can in some cases give rise to further release of Cl atoms. There is thus a clear need for laboratory based studies to establish the mechanism and kinetics of such reactions.

By using flash photolysis coupled to a fast-flow system with nozzle beam mass spectrometric sampling (Fig. 1), we have obtained direct evidence for a number of transient species which are produced in these photochemical systems. The formation of ClO by reaction (3) is confirmed and the first direct evidence for a competing channel leading to elimination of a halogen molecule (reaction (4) below) is presented. Secondary production of ClO following reaction between CCl_3 and O_3 is also reported.

$O(2^1D_2)$ atoms were produced by flash photolysing O_3 in the Hartley continuum (200–300 nm). The flash lamp was constructed of quartz and was operated with a continuous flow of argon at a pressure of ~100 N m^{-2}. Flash energies of 125–250 J (10 µF at 5–7 kV) were found to be adequate when signal averaging was used: the half life of the flash at 260 nm was ~1 ms. Reagents were mixed just before entry into the flow tube (typically, flow rates of 10 m s^{-1}, with total pressures in the range 300–400 N m^{-2} and O_3: halocarbon: He = 1 : 10 : 40 were used). He + O_3 mixtures were prepared by diverting part of the He flow through a trap containing O_3 adsorbed on silica gel at 195 K. Ozone was prepared by the method of Clough and Thrush[7] and the concentration in the flow system monitored optically by absorption at 260 nm; pressures in the range 1–40 N m^{-2} could be conveniently monitored with a path length of 10 cm.

Products of the primary and secondary radical reactions were monitored as a function of time with the mass spectrometer (Extranuclear quadrupole) set to sample a preselected mass number. The analogue output from the mass spectrometer was then digitised and stored in a 200-channel signal averager (Datalab, DL102A); in most cases it was necessary to average the results of sixteen experiments before adequate signal-to-noise ratios were obtained. Little electronic interference from the flash was observed, but some variation with mass number was found and was thus checked for all experimental runs.

Helium (99.9%) and Freons 11, 12 and 13 (Matheson) were taken directly from cylinders. Carbon tetrachloride vapour (laboratory grade) was obtained by pumping on the liquid, and

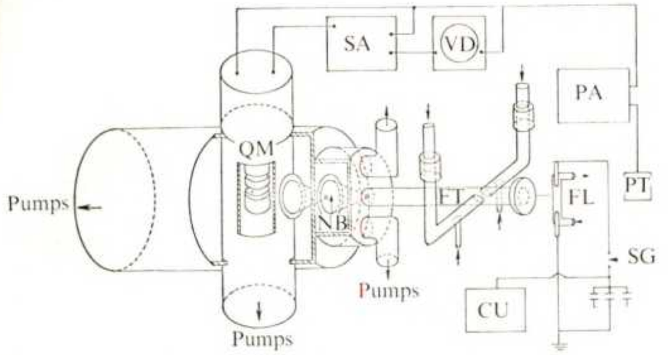

Fig. 1 Schematic representation of the flow tube flash unit and nozzle beam mass spectrometric sampling system: FT, flow tube; NB, nozzle beam sampling system; QM, quadrupole mass spectrometer; FL, flash lamp; CU, charging unit; SG, spark gap; PT, photo-trigger; PA, pulse amplifier; VD, visual display; SA, signal averager.

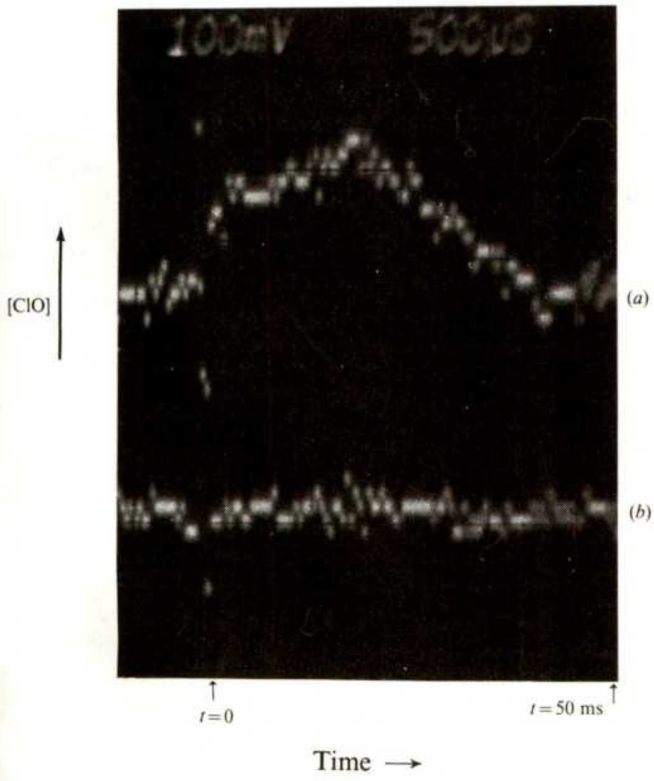
the flow regulated with a needle valve. The purity of all reagents was checked before an experimental run by direct sampling with the mass spectrometer.

The extent of photolysis for pure ozone was generally in the range 3–10% depending on the flash energies used. In the presence of the chlorofluoromethanes the extent of O_3 decomposition was seen to increase significantly as a result of secondary reactions. An increase by a factor of 3–8 was observed using Freon 11–13:ozone ratios around 5. The effect was less marked for CCl_4.

Formation of ClO was observed ($m/e = 51$) following the photolysis of O_3 in the presence of Freons 11–13 and CCl_4 (see Fig. 2), supporting previous observations using ultraviolet absorption spectroscopy[6]. No signal at $m/e = 51$ was observed when O_3 was excluded from the flow mixtures under otherwise identical conditions. The yield of ClO was found to increase with increasing partial pressure of O_3 (over the accessible range 5–13 N m^{-2}), as expected from the increase in $O(^1D)$ production. The yield of ClO also increased with the partial pressure of CF_3Cl, however in the presence of CF_2Cl_2, which is known to give the highest secondary yield of ClO under the conditions used (H. M. Gillespie and, R. J. D., unpublished results), the rate of decay of ClO increased with partial pressure of CF_2Cl_2 (over the range 40–80 N m^{-2}). As ClO is unreactive with closed shell species, this indicates that the concentration of free radicals or oxygen atoms increases as the partial pressure of CF_2Cl_2 is increased. This could be caused by a little photolysis of CF_2Cl_2 and will be examined in more detail in future work. The greatest yields of ClO were observed with CCl_4 (Fig. 2).

Fig. 2 Formation and decay of ClO following the photolysis of O_3 in the presence of CCl_4. *a*, Ozone, CCl_4 and He mixture: $P_{O_3} = 0.05$ mmHg, $P_{CCl_4} = 0.35$ mmHg, $P_{He} = 2.15$ mmHg. *b*, CCl_4 and He mixture: $P_{CCl_4} = 0.35$ mmHg, $P_{He} = 2.15$ mmHg. Mass spectrometer set to sample $m/e = 51(ClO^+)$, resolution set at 4.25; flow velocity = 10 m s^{-1}; traces are the result of averaging 16 experiments.



Other products observed immediately following photolysis of mixtures containing O_3, were FCl, CFClO (both from $CFCl_3$) and CF_2O from CF_2Cl_2. Small yields of CCl_2 and CFCl were also observed from direct photolysis of $CFCl_3$ and CF_2Cl_2 respectively. As these transient species have the same charge–mass ratio at CFClO and CF_2O, a small correction to yields of the latter species was made. A search was also made for the FO radical, however the large background signal at $m/e = 35$ (Cl^+) made measurements at this mass number very insensitive and no firm evidence for the presence of this radical was obtained.

The present work provides further direct evidence for reaction (3) and the first direct evidence for the channel

$$O(^1D) + CFCl_3 \rightarrow CCl_2O + FCl \qquad (4)$$

(secondary formation of FCl through atom recombination would be too slow to account for our observations). Pitts *et al.*[4] have observed CF_2O and CFClO as end products from Freons 12 and 11 respectively and have suggested that reactions similar to (4) were responsible, but secondary reactions can also lead to these end products. Further work to establish the absolute sensitivity of our system for species such as FCl will allow the importance of channel (4) to be assessed quantitatively.

The large yield of ClO from CCl_4 and the continued growth of this radical after the flash (Fig. 2) provides evidence that the CCl_3 radical, formed in the primary reaction between $O(^1D)$ and CCl_4, reacts further with O_3, yielding ClO. Little is known about the mechanism of the secondary reactions involving CCl_3 or CF_xCl_{y-1} radicals with O_3 or O_2, but our work indicates that the $CFCl_2$ radical gives rise to CFClO, possibly by the reactions

$$CFCl_2 + O_3 \rightarrow CFCl_2O^{\ddagger} + O_2 \qquad (5)$$

$$CFCl_2O^{\ddagger} \rightarrow CFClO + Cl \qquad (6)$$

where ‡ denotes vibration excitation, with the chlorine atom reacting further with O_3 to yield ClO.

Energy analysis of wave-power and wind-power systems

THERE have been several recent suggestions that wave-power systems could provide a substantial part of Britain's energy requirements. The development of such systems presents, however, some formidable problems. One which has been largely overlooked concerns the energy investment required in their construction, compared with the predicted rate of energy return. The calculations which follow suggest that the energy recovery period may be many years. Similar calculations for wind-power systems, whose characteristics are known with greater precision, indicate a very much shorter energy recovery period. Moreover, though the wind is often regarded as a diffuse source of power, it is shown to offer a power density comparable with that assumed for wave-power systems.

Since no large scale wave-power system has yet been constructed, it is not possible to determine precise energy costs. There are, however, enough data available for one proposed system, the Salter rocking float[1–3], to provide a reasonable estimate. Salter[1] has shown in laboratory tests that his rocking float is a fairly efficient absorber of wave power and reports that at Station India in the North Atlantic the annual average power in the waves is 77 kW m^{-1}. He therefore suggests that "a few hundred kilometres of installation could meet the total present electrical requirements of the UK". Swift-Hook *et al.*[2] consider the efficiency of the rocking float for waves of various periods and state that a float 50 m in diameter tuned to a wave period of 10 s should theoretically absorb at least 50% of the incident wave power for wave periods in the range 7–17 s. Measured efficiencies are somewhat lower than theoretical predictions, but an overall average efficiency of 50% for a large scale rocking float may be feasible, and this would give a power output of 38.5 kW m^{-1} for a location comparable with Station India. A rocking float 50 m in diameter would have a displacement of ~ 2,000 tonnes (t) per metre length, but if one allows for the connecting structure between floats and the addition of a balancing float to counteract the torque produced by wave action, as suggested by Denton *et al.*[3], the displacement will be appreciably higher. Connected arrays of such rocking floats several hundred metres long have been proposed, giving a floating structure comparable in size to modern supertankers. The steel structure of such tankers accounts for about one quarter of their total displacement. If such a ratio can be maintained for wave-power systems, which are appreciably more complex mechanically, the power output of 38.5 kW m^{-1} would require 500 t per m of steel structure, that is the expected power output would be 77 W per t of steel. The energy required to produce 1 t of steel is 38.7 GJ (ref. 4) and it would therefore be 16 yr before the energy output from this wave-power system repaid the energy investment in its construction. Bearing in mind the severity of the working environment, this period is probably comparable with the lifetime of the structure.

The power output per unit displacement may be increased by reducing the diameter of the rocking float system. Smaller floats are, however, less efficient, and marine experience indicates that the ratio of structure weight to total displacement increases as the draught decreases. On balance it seems probable that reduced draught can give some reduction in the energy recovery period, but it is difficult at this time to quantify the improvement that is possible. Moreover, the energy recovery period of 16 yr calculated for the 50-m rocking float is based on assumptions which are somewhat optimistic. For example, Station India is 700 km offshore and well outside the continental shelf. As Denton *et al.*[3] point out, the cost of bringing electricity ashore by underground cable would be prohibitive if the wave-power systems were > 100 km offshore. Locations closer to the shore are therefore necessary and the power in the waves will be attenuated as the waves travel over relatively shallow water. The degree of attenuation will depend on the chosen location, but Salter[1] provides an example of the magnitude of this effect when he quotes the power in the waves at Seven Stones, off Lands End. Here the annual average wave power is 26 kW m^{-1}, one third that of Station India. There will, in any location, be a further loss of efficiency and power output because of the lack of alignment between the axis of the wave-power system and the incident waves. Allowing for all these factors it seems very doubtful whether the energy recovery period for a rocking float system can be reduced to much less than the estimated 16 yr. Other schemes for extracting power from the waves, such as the hinged float system[5], may possibly have a shorter energy recovery period, but there are insufficient data at present in the literature to provide a reasonable estimate of this.

How do wind-power systems compare with proposed wave-power systems? Over Great Britain as a whole the average power in the wind is at least an order of magnitude greater than the average electricity demand of 30 GW. The wind is usually considered to be a diffuse source of power but in good coastal locations the power flux is comparable with the range quoted for wave-power systems. Wind data[6] for Stornoway, measured at 12 m above ground level (37 m above mean sea level) indicates a year round average wind speed of 7.4 m s^{-1} and an average power flux of 606 W m^{-2}. Up to a height of 50 m, which is comparable with the draught of proposed wave-power systems, this gives an annual average power flux of 30.3 kW per metre length of wind-power installation. To the east of Britain at Bell Rock, which is 20 km offshore and near the Firth of Tay, the corresponding annual average power flux is 32.9 kW m^{-1}. Modern windmills have a peak efficiency of ~ 45% but at high wind speeds the efficiency decreases. Over the complete operating range of wind speeds an average efficiency of 30% can be expected. It has been suggested[7] that 10,000 windmills, each having a rated power output of 1 MW, could produce nearly 10% of our present electricity requirements and save 4.6×10^6 t oil per year. A 1-MW windmill of conventional design would have a diameter of ~ 50 m, and past experience[8] in the construction of windmills of this size and rating indicates that the average power output would be ~ 1,090 W per t of steel. This gives an energy recovery period of ~ 1.1 yr. Modern vertical axis windmills, such as that developed in recent years by Rangi, South and Templin[9,10], promise to give a significantly greater output per unit weight and should reduce the energy recovery period for windmills to a few months.

In conclusion, although wave-power systems apparently have the potential to provide a substantial proportion of Britain's energy, the energy investment in their construction seems large by comparison with their rate of energy return. Wind-power systems, however, have a known and very much shorter energy recovery period, and their use on a moderately large scale could make a real contribution towards meeting Britain's energy requirements.

Dinosaurs, endothermy and blood pressure

THE recent resurgence of speculation about dinosaur physiology and behaviour has resulted in two notable and debatable interpretations. Bakker[1] summarises evidence of several investigators and concludes that dinosaurs were endothermic. Coombs[2], among others, suggests that the sauropod dinosaurs were mainly terrestrial, only occasionally entering shallow water. These hypotheses might well be viewed in the light of one line of evidence concerning the relationship between height of animals and hydrostatic pressures in the vascular system. Size alone can provide important insights into dinosaur cardiovascular performance which necessarily relates to the questions of endothermy and habitat. This report shows firstly, that high arterial blood pressures in large dinosaurs are consistent with the proposal that they were endothermic. Secondly, I suggest that if the long-necked sauropods were aquatic, they thereby avoided tremendous hydrostatic stresses on the cardiovascular system.

High tissue metabolism in endotherms demands high blood pressure and rapid flow in the systemic circuit to provide adequate exchange of metabolites. Blood flow must be equally rapid in the pulmonary circuit for efficient gas exchange, but the pulmonary blood pressure must be comparatively low to prevent either fluid filtration through the gas exchange surface[3] or energy waste inherent in excessive precapillary resistance. The evolutionary trend among vertebrates proceeds from the fishes which perfuse the gas exchanged at higher pressures than the other tissues, through amphibians and reptiles with roughly comparable pressures in two parallel circuits, to endotherms with high systemic and low pulmonary pressures[4]. A four-chambered heart and complete anatomical separation of the circuits seem to be required to maintain the large pressure difference between the circuits in endotherms.

Dinosaurs must have had systemic blood pressures high enough to move the blood from the heart to the head. The terrestrial bipedal ornithopods and theropods, for example, must have had central systemic blood pressures equal to at least the hydrostatic pressure of the blood column above the heart plus the head perfusion pressure. The vertical distances between the heart (centre of anterior body cavity) and the head in several large dinosaurs (Table 1) indicate that central blood pressures characteristic of living reptiles (about 20–70 mmHg)[5] could not even prevent collapse of the vessels in the head of the large dinosaurs much less provide adequate perfusion pressures. Because it is reasonable to assume that pulmonary blood pressure in dinosaurs was limited by the same constraints as in living air breathers, it is likely that at least these large dinosaurs had four-chambered hearts capable of producing large differences in pulmonary and systemic pressure.

Bakker[6] noted that, among all living vertebrates, only endotherms include animals with "fully erect gait" and he therefore suggested that dinosaurs were endothermic. By "erect", however, he meant somewhat more than simply a large heart–head distance and he was criticised for not showing the physiological basis for this correlation between gait and endothermy[7,8]. The relationship may be that both endothermy and high blood columns require high central systemic blood pressure. Thus, sustained high blood pressure inferred from the large vertical distance between the heart and the head in some dinosaurs supports (but does not prove) the proposition that dinosaurs were endotherms. Perhaps the advent of endothermy with its concurrent development of high systemic perfusion pressure enabled dinosaurs to become large and erect. The endotherms are the only living terrestrial vertebrates having heads more than about 50 cm above the heart. (Some snakes have long heart–head distances but they are subject to fainting if held in a vertical head-up position[9].) Consistently, short vertical heart–head distances characterise primitive reptiles which are thought to be ectothermic on the grounds of bone histology (see ref. 11 for literature) and predator–prey ratios in fossil bone deposits[10].

The sauropods present another interesting haemodynamic problem because of the extreme length of their necks. A specimen of *Brachiosaurus* in the Berlin Museum, for example, showed a vertical blood column of about 6.5 m above the heart; this would require a ventricular pressure of over 500 mmHg just to support the column[12]. The hearts of other large sauropods also must have had to develop high pressures if these dinosaurs held the head continuously erect and were terrestrial (Table 1). On the other hand, if the sauropods were aquatic, the blood pressure would be more or less equalised by the external hydrostatic pressure, thus placing less strain on the heart muscle.

It can be shown that vertebrate cardiac muscle operates within a limited range of ventricular wall stress. When the stress increases owing to pressure, the myocardium thickens, tending to normalise the stress. Not only does this adaptation occur within individual hearts, it also appears in phylogenetic comparisons. Both mean blood pressure and heart weight are generally 30–40% higher in birds than in mammals[5,13] for example. Giraffes, which have the highest blood pressure among mammals[14], are said to have hypertrophied hearts[15].

To estimate the degree of hypertrophy in sauropod hearts, I calculated the ventricular wall stresses in ten species of birds and mammals for which appropriate data are available (mouse, rat, dog, man, horse, cow, hen, turkey, and two ducks). The spherical model used is not precise but it is useful in a comparative way. According to the model, the mean stress averages about 1.0×10^5 dyne cm^{-2} ($\pm 0.3 \times 10^5$, the 99% confidence interval) in the species examined. If the heart of a 50-tonne sauropod was the same weight as that of a similarly sized whale (~ 200 kg)[16], it could have sustained pressures within the living vertebrate range. Under the assumptions that it operated within the range of stress indicated above, and it had to withstand pressures greater than 500 mmHg, it is evident that the heart would have been at least eight times heavier than the whale's heart but with the same internal ventricular volume. The spherical model increasingly underestimates stress in real hearts as the wall thickness: ventricular volume ratio increases with higher blood pressure[17]. Therefore the estimate of a 1.6-tonne heart is conservative. Such a thick-walled ventricle would be mechanically inefficient and its rate of oxygen consumption would be high. These potential disadvantages of extremely high blood pressure, as well as others listed by Hohnke[12], provide evidence favouring aquatic habits in sauropods.

Table 1 Estimated vertical distances between the head and heart in some large dinosaurs* and the associated hydrostatic pressure of the blood column

	Vertical distance (cm)	Hydrostatic pressure (mmHg)
Ornithopoda		
Hadrosaurus	100–150	77–116
Anatosaurus	200	155
Theropoda		
Ceratosaurus	90–150	70–116
Antrodemus	100	77
Tyrannosaurus	200–240	155–185
Sauropoda		
Apatosaurus	201	156
Brachiosaurus	655	508
Diplodocus	650	502
Camarasaurus	550	425

* Estimates from refs 12, 18 and 19.

Nevertheless, the possibilities remain that the sauropods achieved terrestrial life by possessing extremely hypertrophied hearts or an unusually strong myocardium. Alternatively, they simply might not have raised their heads high, or if they did, they endured a temporary cessation of blood flow to the brain.

I thank F. N. White and G. Sanson for stimulating discussion. This work was supported in part by a grant from the Australian Research Grants Committee.

Acetylene reduction by legume root nodule protoplasts

NITROGEN-FIXING protoplasts are of obvious importance in physiological studies of the assimilation of atmospheric nitrogen; in investigations of nodule development; in cloning trials for experimental and agricultural purposes[1]; and in somatic cell hybridisation[2–5]. Production of such protoplasts has proved elusive, however. Davey *et al.*[6] introduced a technique for the isolation of protoplasts from nodules. Protoplasts prepared by their procedure were incapable of nitrogenase (EC 1.7.99.2)-dependent acetylene reduction[7], presumably as a result of the extensive loss of leghaemoglobin during the isolation process[7]. By modifying the original procedure[6], we have obtained naked protoplasts which reduce acetylene after a lag period of about 2 d, and continue to do so for at least 11 d.

Protoplasts were isolated in a medium containing the following: 1% (w/v) Rhozyme HP 150 (Rohm and Haas); 0.5% (w/v) pectin lyase (EC 4.2.2.3 (ref. 8), Kikkoman Shoyu, Chiba-ken, Japan); 1% (w/v) cellulase (EC 3.2.1.4) (Onozuka R-10, Kinki Yakult Co., Tokyo); 1% (w/v) bovine serum albumin (Sigma) and a wash medium consisting of 0.6 M sorbitol; 0.05 M HEPES; 0.3% (w/v) potassium dextran sulphate (to inhibit protoplast fusion)[9]; 0.2 mM KH_2PO_4; 0.1 mM $MgSO_4$; 0.1 mM $CaCl_2$; 1.0 µM KI; 0.1 µM $CuSO_4$; with or without 1 mM KNO_3. The *p*H of the entire medium was adjusted to 5.8. Protoplasts were prepared from freshly harvested nodules of garden grown *Vigna unguiculata* (L.) Walp plants as previously described[7]. After collection, cells were separated from contaminating rhizobia by decantation in sterile wash medium. Settling of protoplasts was aided by gentle centrifugation (10*g* for 1 min), fresh wash medium was added and the process was repeated 10–15 times to give a final dilution of any extraneous rhizobia of 10^{10}–10^{15} times. The protoplasts (about 5×10^8 per ml) were incubated in 1.5 ml of wash medium at 25 °C, and acetylene reduction was assayed as described elsewhere[10].

Protoplasts obtained in this manner were intact as judged by light microscopy, possessed most of the original leghaemoglobin content[7], and began to reduce substantial amounts of acetylene after a lag period of between 24 and 48 h (Fig. 1*a*). Further evidence for the structural integrity of the protoplasts was deduced from the observation that when they were plated out on agar suitable for the growth of soyabean callus[11], rhizobial colonies were not formed, yet rhizobia from within the protoplasts (UMKL 76) were capable of good growth on this medium when cultured separately. The extent of the lag period could be reduced by removing NO_3^- from the wash medium used for incubation, but the presence of NO_3^- seemed to be essential during protoplast isolation. Represession of nitrogenase activity by NO_3^- is well known[12], and it is possible that NO_3^- levels must decrease to non-inhibitory concentrations before acetylene can be reduced.

Various substances were added to the incubation medium to test their effect on acetylene reduction. For example, 20 µmol of ATP stimulated it about sixfold (Fig. 1*b*). Other nucleotides had a similar effect. Similarly, phospho(enol)pyruvate and succinate enhanced acetylene-reduction activity, and the effect in the early stages of treatment was even greater than with ATP (Table 1). Addition of *V. unguiculata* leghaemoglobin to the medium (10–20 µmol) completely inhibited development of acetylene reduction activity. Most of these effects are similar to those seen in cell-free extracts of nitrogenase, and with nitrogenase in bacteroid preparations.

Holsten *et al.*[13] demonstrated that rhizobia could enter cultured soyabean callus cells. Under the microscope, the rhizobia could be seen within vesicles inside the host cells, and

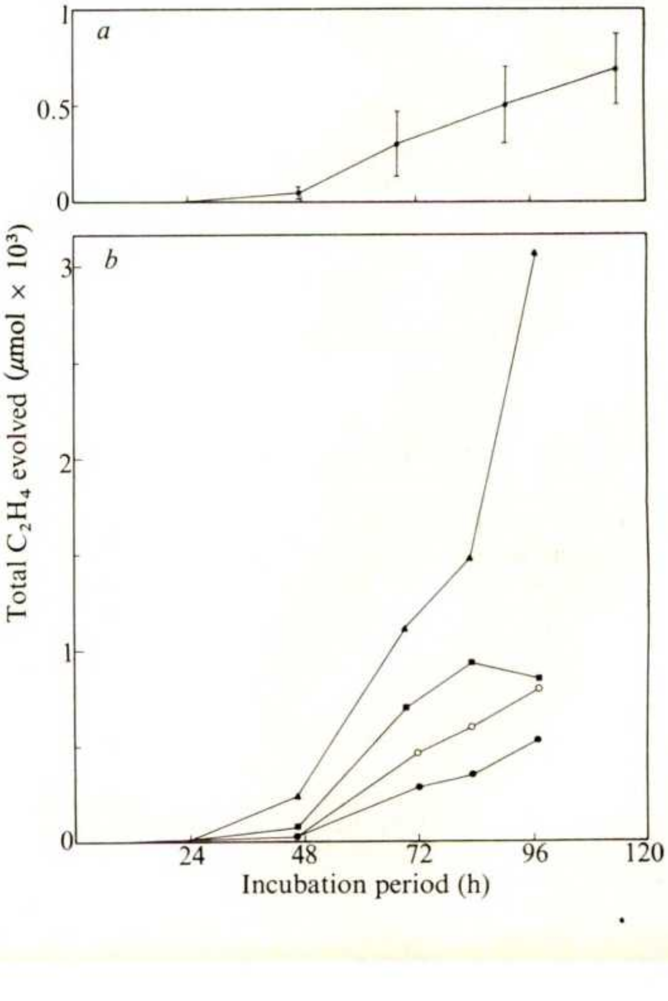

Fig. 1 *a*, Rate of acetylene reduction by protoplasts isolated from legume root nodules. Yields were within the range 30–50 mg dry weight of protoplasts extracted from 1 g fresh weight of nodules. Acetylene reduction was assayed in serum bottles of 29.5 ml capacity as described elsewhere[10]. Endogenous ethylene production was negligible (<0.01 nmol at the end of the experiment). Each point is the mean ± 1 s.d. of four replicates. *b*, Rate of acetylene reduction by protoplasts incubated with various amounts of ATP (amounts shown in µmol). Protoplasts were isolated from 1 g fresh weight of nodules and yielded 30–50 mg dry weight of material. ▲, + 20 µmol; ■, + 10 µmol; ○, + 5 µmol; ●, control.

Table 1 Effect of phospho (enol)pyruvate and succinate on acetylene reduction by root nodule protoplasts of *V. unguiculata*

Age of protoplasts (d)	Acetylene reduction (nmol C_2H_4/mg dry weight/h)		
	Protoplasts	Protoplasts + phospho (enol)pyruvate (40 μmol)	Protoplasts + succinate (40 μmol)
3	0.10 ± 0.01	0.52 ± 0.06	0.17 ± 0.01
4	0.11 ± 0.01	1.98 ± 0.20	1.44 ± 0.09
5	0.09 ± 0.03	3.28 ± 0.91	2.59 ± 0.62
6	1.08 ± 0.04	6.14 ± 0.80	6.20 ± 1.22
7	2.13 ± 0.15	9.42 ± 1.72	6.87 ± 1.70
8	2.04 ± 0.36	8.05 ± 2.04	7.21 ± 1.79
9	3.76 ± 0.32	11.06 ± 3.17	9.25 ± 1.80
11	3.45 ± 0.81	12.57 ± 2.73	13.09 ± 2.46

Each value is the mean (±1 s.d.) of three replicates. Protoplast dry weights were determined at the end of the experiment after oven drying at 80 °C until constant weight.

in this condition reduced acetylene to ethylene. Later work demonstrated acetylene reduction by rhizobia in the presence of plant callus cultures$^{14-16}$, although there was no direct contact between bacteria and plant. Then in late 1975 many authors showed that the rhizobia themselves could fix nitrogen in the absence of legumes$^{17-21}$. For these reasons it was imperative to show that the acetylene reduction reported above occurs within the plant membrane of the isolated protoplasts. As discussed, the protoplasts did not release rhizobia when cultured on an agar medium. Also, protoplasts which were actively reducing acetylene could be filtered on to nylon mesh (pore size 40 μm), washed extensively, and still retain the nitrogenase activity even in the semi-dry state. Furthermore, the wash-medium did not support acetylene reduction by the free-living UMKL 76, even with numbers as high as 4×10^{10} rhizobia per ml.

Thus the acetylene reduction observed in these experiments occurred within the cytoplasm of intact protoplasts. Maximum rates of reduction approximated 2–5% of that observed in fresh nodules (and this does not take into account the yield of protoplasts). In other experiments, rates of reduction of 12–13 nmol C_2H_4 produced per mg dry weight per hour were observed, which compares favourably with the reported values of about 46 nmol C_2H_4 produced per mg dry weight rhizobia per h (ref. 21).

We thank Mr R. Jesinger, Rohm and Haas Co, and Dr S. Ishii, Kikkoman Shoyu Co., for enzymes. Financial assistance was provided by the International Foundation for Science (Stockholm) and the University of Malaya.

Inhibition by acetylene of conventional hydrogenase in nitrogen-fixing bacteria

ONE of the earliest observations associated with nitrogen fixation was that all nitrogen-fixing organisms contained hydrogenase and nitrogenase[1]. We show here that acetylene, which is widely used as a substrate for nitrogenase, inhibits conventional hydrogenase activity and thus prevents the uptake of H_2 formed by nitrogenase in the presence of CO. Our evidence also suggests that azotobacter nitrogenase forms H_2 *in vivo* and that hydrogenase reoxidises this H_2 to provide reducing power for metabolism.

Hydrogenase can be classified into two major types: first, the ATP-dependent hydrogen-evolving capacity of nitrogenase, which accounts, in part, for the above correlation, and second, the hydrogenase which is not dependent on ATP. This second type can be subdivided into the reversible hydrogenases, common in anaerobic bacteria and presumably used as an electron sink to maintain a constant level of oxidised ferredoxin (or equivalent electron carrier), and the unidirectional, hydrogen-oxidising type found in azotobacter[2,4] and some nitrogen-fixing bacteroids[3]. Dixon[3] suggested three possible functions for this unidirectional hydrogenase: (1) as an oxygen scavenger to supplement respiratory protection of nitrogenase; (2) to prevent the H_2 evolved by nitrogenase from inhibiting the enzyme, and (3) enhancing the efficiency of nitrogenase by recycling the evolved H_2. There was little supportive evidence for these possibilities and the failure to observe H_2 evolution by nitrogen-fixing azotobacter under CO and argon, conditions favourable for any such evolution, led Postgate[5] to suggest that the nitrogenase site was anhydrous *in vivo* and that the hydrogen ion was unable to reach it. Brotonegoro[6], however, observed that nitrogen-fixing *A. chroococcum* evolved H_2 in the presence of CO if C_2H_2 was also present. We have investigated this observation.

The organisms used in this study were *Azotobacter chroococcum* (N.C.I.B. 8003) and *Klebsiella pneumoniae* M5A1. The growth, harvesting and preparation of crude supernatant extracts from these organisms have been described elsewhere[7,8]. Whole cells of *A. chroococcum* were obtained from batch cultures (100-ml volumes shaken in 250-ml conical flasks under air at 30 °C) and the *K. pneumoniae* cells were from a glucose-limited chemostat culture repressed for nitrogen fixation[9].

For the enzyme assays, the nitrogenase activity in crude supernatants[7] or whole cells[10] of *A. chroococcum* was measured by acetylene reduction or H_2 evolution[8]. Hydrogenase activity in both *A. chroococcum* and *K. pneumoniae* was determined manometrically[2,11].

Table 1 shows clearly that acetylene inhibited the ATP-independent H_2-evolving capacity of the reversible hydrogenase of *K. pneumoniae* and the H_2-oxidising capacity of the unidirectional hydrogenase of *A. chroococcum*, but that it did not inhibit the ATP-dependent H_2-evolving capacity of nitrogenase. C_2H_2 seemed to be a more effective inhibitor of hydrogenase than CO, particularly with whole cells of *A. chroococcum*.

Table 2 shows the effect of CO and C_2H_2 on hydrogen evolution by whole cells of *A. chroococcum*. The effect of the inhibitors varied with different batches of cells but 5% CO consistently inhibited acetylene reduction by > 95% and the rate of H_2 evolution was always greater in the presence of both CO and C_2H_2 than with either gas alone. NH_4-grown cells, repressed for nitrogenase activity, did not evolve H_2; this strongly suggests that the enzyme responsible in N_2-grown cells is nitrogenase.

We have confirmed the observation made by Brotonegoro[6] and extended it to show inhibition of conventional hydrogenase by acetylene. The evolution of H_2 which occurs

Table 1 Inhibition by acetylene and carbon monoxide of hydrogenase activity

Concentration of inhibitor (% C_2H_2 in gas phase)	Inhibition %				
	ATP-independent hydrogenase				ATP-dependent hydrogenase Crude preparation of nitrogenase from *A. chroococcum**
	Reversible hydrogenase from *K. pneumoniae*		Unidirectional (H_2 uptake) hydrogenase from *A. chroococcum*		
	Whole cells	Crude supernatant	Whole cells	Crude supernatant	
3.7	67				
6.5	82				
5.0		45	51(7)†	51(36)	0(0)
10.0		85	75	83	0
20.0			96	95	0

K. pneumoniae hydrogenase was measured in NH_4-grown cells and supernatants which contained no nitrogenase activity: H_2-evolving activity of whole cells (2.3 ml, 0.6 mg of protein) with added glucose (46 mM) was measured manometrically at 30 °C under argon. Crude supernatants (2.4 mg of protein) were also assayed manometrically under argon at 30 °C in 70-mM HEPES buffer, *p*H 7.2, $Na_2S_2O_4$ (20 mM) and methyl viologen (2 mM) in a final volume of 2.3 ml. The reactions were started by tipping either glucose or $Na_2S_2O_4$ from the side arm. *A. chroococcum* hydrogenase was measured manometrically at 30 °C by following H_2 uptake in 100-mM phosphate buffer *p*H 8.0, containing washed cells (0.5 mg (dry weight)) or crude supernatants (3.4 mg protein) with potassium ferricyanide (24 mM) as the electron acceptor. The atmosphere contained H_2 (80%), C_2H_2 as indicated with argon as the normalising gas.

Acetylene also failed to inhibit the H_2-evolving capacity of nitrogenase from *K. pneumoniae* in the presence of CO (Dr B. E. Smith, personal communication).

*The ATP-dependent H_2-evolving capacity of nitrogenase in crude supernatants of *A. chroococcum* was measured in the presence of 20% CO to prevent competition for electrons between the acetylene-reducing site and the H_2-evolving site. Otherwise, the assay conditions were as described by Yates and Planqué[7].

†The figures in parentheses show % inhibition by 5% CO.

when *A. chroococcum* is treated with both CO and C_2H_2 can now be interpreted simply; CO blocks all but the hydrogen-evolving function of nitrogenase[12] and CO plus C_2H_2, but mainly C_2H_2, blocks the conventional unidirectional hydrogenase which would otherwise reoxidise the hydrogen formed by nitrogenase. In experiments not reported here, the aerobe *Mycobacterium flavum* 301 shows a similar pattern of responses to CO and C_2H_2.

Table 2 H_2 evolution and acetylene reduction by N_2-fixing *A. chroococcum*

Amount of gas added to the atmosphere	C_2H_2 reduced (nmol h^{-1})	H_2 evolved (nmol h^{-1})
none	0	0
10% C_2H_2	780	20
5% CO	0	440
10% C_2H_2+5% CO	5	760

The nitrogenase activity of *A. chroococcum* was measured in 10 ml suspensions of whole cells (0.25 mg dry weight ml^{-1}) in 25-ml conical flasks at 30 °C under a PO_2 of 0.05 atm.

These results given a clear indication that H_2 is formed by azotobacter nitrogenase *in vivo* but, instead of being evolved, it is normally reoxidised by hydrogenase to provide additional reducing power for metabolism. This recycling of H_2 formed by ATP-dependent nitrogenase activity coupled with the ability of H_2 to support oxidative phosphorylation in azotobacter[2] may partly explain the apparently greater efficiency of nitrogenase in azotobacter compared with *C. pasteurianum*[13]; ATP-independent hydrogenase evolves H_2 during growth of *C. pasteurianum*. Thus, the evidence suggests that possessing hydrogenase improves the economy of N_2-fixing aerobes, so the correlation between hydrogenase and nitrogenase[1] now has a rational basis.

We wish to thank Professor J. R. Postgate and Dr Herman Bothe for useful discussions and Mrs Frances Campbell for technical assistance.

Linear relationship between phytochrome photoequilibrium and growth in plants under simulated natural radiation

DEVELOPMENT in higher plants is highly responsive to environmental factors, the most important, in natural conditions, being light. Perception of light quality involves at least two photoreceptors, of which phytochrome is the better understood[1]. Most work on its function, however, has been carried out with etiolated (that is dark grown) seedlings irradiated from relatively narrow wave band sources. There is no direct evidence on the function of phytochrome in the natural environment[2]. Using simulated natural radiation conditions, we have now found evidence to support the hypothesis that phytochrome acts to detect mutual shading through the changed quality of natural radiation, and to redirect development appropriately[3].

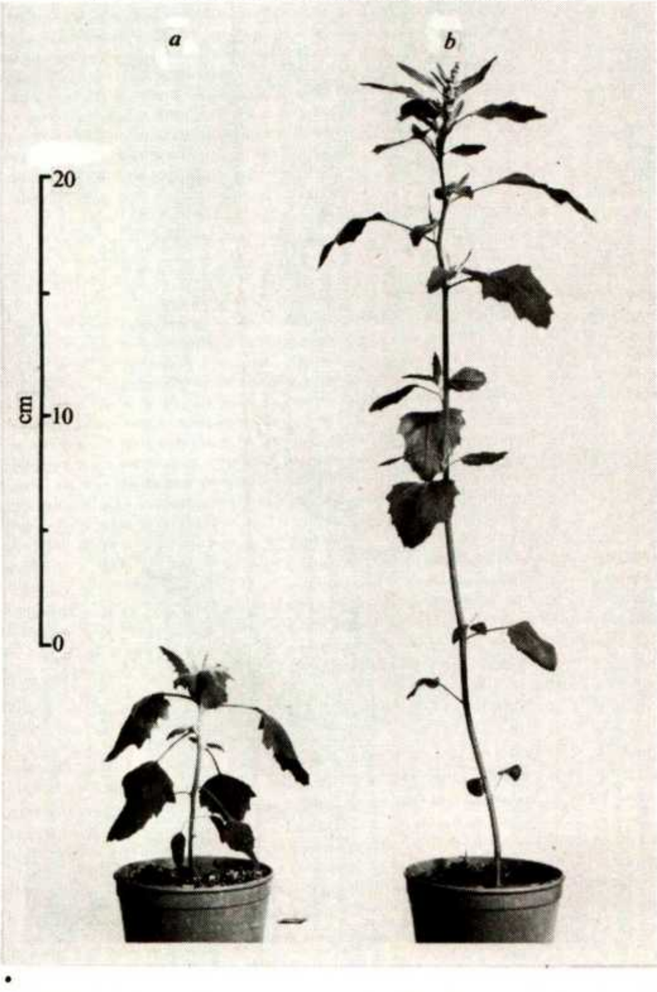
Phytochrome is a photochromic protein existing in two interconvertible forms; P_r, which absorbs maximally at 660 nm; and P_{fr}, absorbing maximally at 730 nm (ref. 1). Thus, in continuous irradiation with broad-band sources absorbed by both P_r and P_{fr}, a photodynamic equilibrium is achieved characterised by the steady-state proportions of P_r and P_{fr}. This photoequilibrium is usually determined as P_{fr}/P_{total} and is known as φ. We have recently shown that φ can be quantitatively related to the ratios of the quantum flux densities at 660 nm and 730 nm (known as ξ) using a range of natural and artificial radiation sources[3]. In addition, certain parameters of development were shown to be related, through φ, to ξ, in a predictable, although non-quantitative, manner[3]. We report here a direct linear relationship between a growth parameter (the logarithmic stem extension rate) and apparent phytochrome photoequilibrium (φ) as estimated from quantum flux density ratios (ξ).

In this work seeds of fat hen (*Chenopodium album* L.), a common weed of arable land, were collected from the field, germinated and grown to the third leaf stage in a controlled environment room (16 h, 20 °C day: 8 h, 15 °C night) under radiation from a bank of 80-W Warm White fluorescent tubes providing a quantum flux density of 180 μE m^{-2} s^{-1} of photosynthetically active radiation (PAR) as defined by McCree[4]. Seedlings selected for uniformity were then transferred to the light treatment chambers using the photo- and thermoperiod conditions described above.

The experimental light sources were designed to provide equivalent amounts of PAR using 6×2 foot 40-W Colour Matching 55 fluorescent tubes. To vary the phytochrome photoequilibrium while maintaining constant PAR, additional far red (>660 nm) radiation was provided from 60-W unfiltered tungsten bulbs, or from a bank of water-cooled 150-W clear tungsten filament lamps filtered through a red and a green sheet of Perspex. The PAR in all treatments was adjusted to 100 μE m^{-2} s^{-1}. The added far red radiation allowed a range of estimated phytochrome photoequilibria between $\varphi = 0.71$ and $\varphi = 0.29$. The spectral energy distribution of each radiation source was measured and the apparent phytochrome photoequilibria estimated from the ξ values as described previously[3].

Figure 1 shows the appearance of two originally identical seedlings after treatment with radiation of equal photosynthetic effectiveness but different ξ values for 21 d. The lower phytochrome photoequilibrium established in the plants given added far red radiation has led to extreme modification of developmental pattern. In particular, stem elongation, branching, flowering, and leaf pigmentation are modified.

Fig. 1 Photograph of *Chenopodium album* seedlings grown for 21 d under radiation sources providing equal quantum flux densities in the photosynthetically active regions (100 μE m^{-2} s^{-1}) but with different amounts of far red radiation establishing different phytochrome photoequilibria. The estimated photoequilibria under the two sources are *a*, 0.71; *b*, 0.38.



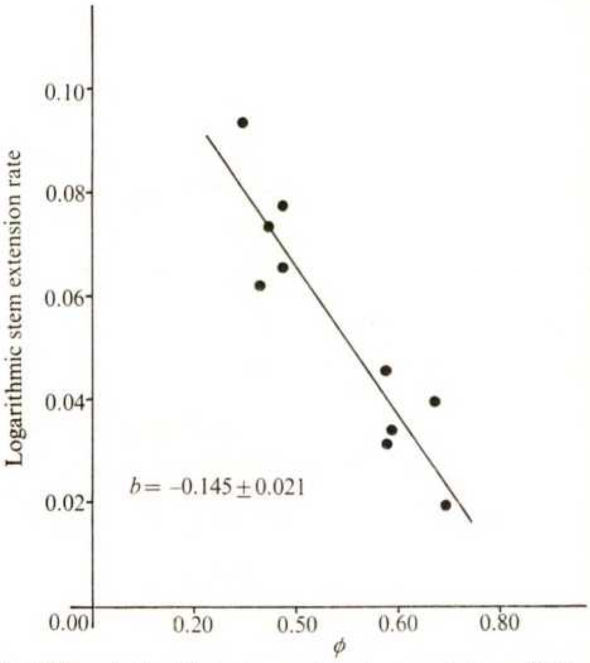


Fig. 2 The relationship between phytochrome photoequilibrium (φ) and the logarithmic rate constant of stem extension for *Chenopodium album* seedlings growing under equal amounts of PAR. The line has been fitted by regression analysis, and the correlation coefficient is −0.924.

During the early period of growth, *Chenopodium album* seedlings grow exponentially with respect to overall height. When plants were grown under radiation sources providing equivalent PAR but different phytochrome photoequilibria, the logarithmic rate constants of stem elongation were found to be directly, and linearly, related to the estimated phytochrome photoequilibria (Fig. 2). Other parameters of development are also related to φ, but the linear relationship with the logarithmic stem extension rate is the most clearcut response noted. Many workers have previously shown that a modification of φ at the end of the daily light period has substantial effects on growth[5-10]. In more detailed experiments to be published elsewhere, we have demonstrated that the phytochrome photoequilibrium established during the light period is responsible for at least 80% of the change observed in stem extension rate, and end-of-day effects, although important, are quantitatively much smaller, although again linearly related to φ, as first shown by Vince-Prue[8]. We have also shown that the linear relationship presented in Fig. 2 is not merely a quirk of *Chenopodium album*; it has been seen in other species including the stinging nettle (*Urtica dioica*) and rose-bay willow-herb (*Chamaenerion angustifolium*). A survey of sun- and shade-plants is being undertaken to search for systematic variation in responsivity to light quality.

These data strongly support the hypothesis we previously proposed that the principal function of phytochrome is to detect the quality of light in the red and far red wavelength regions, and thus to perceive mutual shading[2,3]. For plants adapted to an herbaceous (that is non-phanerophytic) habit, competition for light is extremely important, and a sensitive mechanism for response to mutual shading is clearly of great adaptive value.

The authors are grateful to the Natural Environment Research Council for financial support of this work.

Hydromechanical adaptation in the solitary free-living coral *Fungia scutaria*

THE scleractinian coral *Fungia scutaria* produces a dense, diskoid skeleton that is adapted for stability and abrasion resistance in turbulent water. Water motion rights skeletons at velocities lower than needed to disturb upright corals. Flow of water over the coral is controlled largely by passive hydromechanical adaptations. Previous reports[1–3] suggest that muscular activity is the main mechanism enabling free-living solitary corals to follow their peculiar way of life. Our work indicates that passive hydromechanical adaptations can be a more important factor in shallow turbulent waters. Several species of free-living corals are known to migrate, avoid burial, and right themselves by action of their polyp[1,2] or by symbiotic activity of sipunculid worms[3]. Most other Indo-Pacific solitary corals such as *F. scutaria* are inactive, yet remain upright in turbulent waters. Dead skeletons of *F. scutaria* are generally found with the oral surface upward, and seem to resist erosion far better than other corals. We overturned dead skeletons in one area; they were righted during the next period of heavy waves, suggesting unique hydraulic and structural properties of the skeleton.

Fungia stability was tested on an intertidal bench subjected to wave-induced unidirectional flow of 30–50 cm s^{-1}. Occasional swells swept across the bench and accelerated flow. Between surges *Fungia* skeletons were set out, either upright or inverted. In the wake of the surge, the resting position of each skeleton was noted. Inverted skeletons were righted by single surges of 1–2 m s^{-1}. Overturned skeletons exposed to a single surge were righted 40 out of 50 times, whereas upright corals remained undisturbed in 49 out of 50 trials. The skeletons generally came to rest with their long axis parallel to the direction of current flow, reducing the cross-sectional area presented to the current and increasing stability.

About 70% of *Fungia* found on a reef flat in Kaneohe Bay, Hawaii, rested upright with their long axis aligned within 30° of the local set of storm waves. The hydraulic response of *Fungia* is similar to that of concavo-convex structures such as pelecypod valves in shallow marine environments[4,5]; in the case of *Fungia*, this response has adaptive significance.

Water flow over the coral surface was observed in a flume. Dye injected from a syringe was used to trace flow. In moving water, dye in contact with living or dead corals moves slowly towards the stomodaeum. The rough surface creates frictional drag and decreases water velocity at the boundary. For example, in a current of 30 cm s^{-1} (Fig. 1*d*) water moved at 0.3 cm s^{-1} on the downstream portion of the coral directly against the current and at 1 cm s^{-1} on the upstream portion of the disk. The radial exert septae have a major role in directing and reducing flow. Dead skeletons and living corals with contracted polyps direct flow into the stomodaeum (Fig. 1*d*); corals with expanded polyps or dead skeletons smoothed with cement (Fig. 1*e*) do not so direct the flow. In cross section *Fungia* resembles an airfoil, and a moving fluid induces a low pressure area over the stomodaeum. Reduction in current velocity at the coral surface permits flow into this area of low pressure and probably fascilitates ciliary control of the surface film[6] in all current conditions.

The ability of the living polyp to right the skeleton on various substrata and the role of burrowing crabs in the process were tested in continuous flow aquaria. Live corals and dead skeletons in a graded series of 10–100 g wet weight were placed upside down on the substrata (Table 1). Substrata used were sand, gravel and hard bottom. One experimental series included approximately 15 xanthid crabs (carapace width 3 cm). The other series excluded crabs. Although many of the live *Fungia* eventually righted themselves on the rubble substratum, the process took several days (compared with minutes for more active species[1,2]). Corals on sand and hard substratum did not right themselves. Crabs had a minor role in righting the corals, overturning two dead skeletons.

Ability to migrate to the surface was tested by burying ten living *Fungia* under 1 cm of sand. No coral reached the surface; all were dead at the end of 7 d. Strong currents and wave motion in the typical shallow water *F. scutaria* habitat causes erosion; the coral must avoid abrasion by moving rubble, overturning, and physical removal rather than *in situ* burial. Unlike its relatives which inhabit calm deep water (where sediments eventually come to rest), this species does not ordinarily encounter thick deposits of fine sediment.

Resistance to abrasion was tested for the four most abundant coral species in the area (Table 2). Live corals were tagged and the skeletal weight measured using the buoyant weighing technique[7]. The corals were placed in a cement mixer containing screened carbonate gravel of 2 cm diameter and flowing seawater. The drum of the mixer was then rotated 20 times in 1 min. The corals and abraded fragments were returned to a continuous flow aquarium and reweighed. The test fragmented the branched

Fig. 1 *F. scutaria* in unstable overturned position will begin rolling when subjected to strong current surge (*a*), presenting a larger cross section to water flow. This rights the coral (*b*, *c*) and leaves it in a stable position (*d*). Flow patterns over the surface of a living coral with a contracted polyp (*d*) are compared with that of the coral with an expanded polyp (*e*).

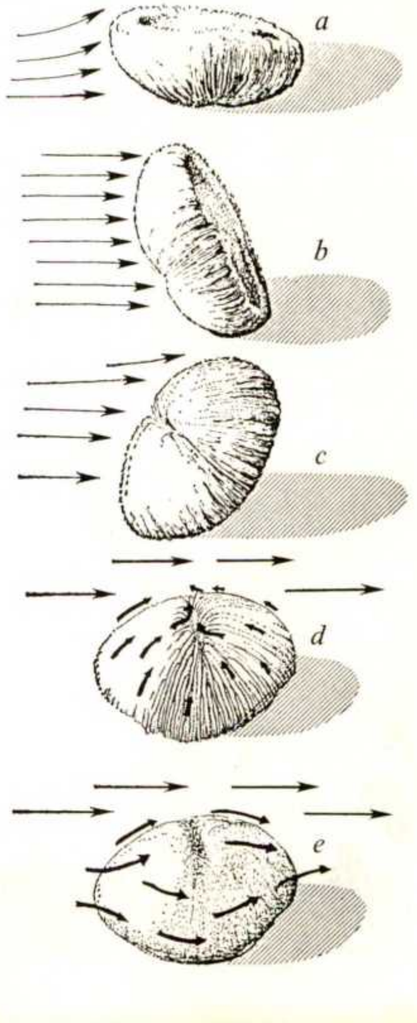

Table 1 Ability of *F. scutaria* to right themselves

	Position after 7 d			
	Live corals		Dead coral skeletons	
	Inverted	Upright	Inverted	Upright
Hard bottom with crabs	9	1	10	0
Hard bottom with crabs	9	1	10	0
Hard bottom without crabs	9	1	10	0
Hard bottom without crabs	10	0	10	0
Rubble with crabs	4	6	9	1
Rubble without crabs	3	7	10	0
Sand with crabs	10	0	9	1
Sand without crabs	10	0	10	0

colonial species and removed all tissue on exposed surfaces. *Fungia* remained intact and lost only a small amount of tissue and skeletal material on the septal margins and costal spines. The septocostal ornamentation fends off the abrasive rubble and protects exposed tissue.

Fungia lost only 1% of its skeleton compared with 40–80% loss for the other species (Table 2). Only the bases of the colonial species remained intact. Tissue regeneration in *Fungia* was complete in 5 d. Colonial corals and abraded fragments lost most of their tissues and died within a few days. *Porites* and *Montipora* eventually showed slight regeneration on the damaged bases, but approximately 90% of the original tissue area was killed.

Table 2 Abrasion resistance, density and cross sectional area/weight ratio of common Kaneohe Bay corals (five corals of each species)

Species	% Loss in abrasion test		Dry skeletal density (g cm^{-3})		Cross-sectional area/buoyant weight ratio (cm^2 g^{-1})	
	Mean	s.d	Mean	s.d.	Mean	s d.
F. scutaria	1.4	0.6	1.86	0.06	0.25	0.03
Montipora verrucosa	38.8	9.5	1.47	0.12	1.36	0.16
Porites compressa	47.4	17.1	1.53	0.06	0 59	0.12
Pocillopora damicornis	79.6	6.8	1.70	0 17	0.64	0.16

Fungia has the highest skeletal density of the species tested. It also shows a very low cross sectional area per unit buoyant weight, producing a stable low drag profile in moving water (Table 2). Specimens weighing as much as 3 kg have a centre of gravity within 2 cm of the substratum. Branched species of similar mass have a centre of gravity at least 5 cm above the substratum, leading to instability and a need for attachment. The high density of *Fungia* and its low surface-to-volume ratio[8] enhance abrasion resistance.

Thus, in addition to use of muscular activity, hydromechanical adaptation is a significant factor in many species of solitary free-living corals. *F. scutaria* is typical of solitary shallow water fungiids which have evolved hydrodynamically stable abrasion resistant skeletons. These corals passively use the surrounding energy field of moving water to their advantage, eliminating the need for a strong, muscular, active polyp.

Reshedding of *Toxoplasma* oocysts by chronically infected cats

INFECTION with *Toxoplasma gondii* is prevalent in man and animals. It can be acquired congenitally by the foetus from an infected mother[1], but also throughout life by eating undercooked meat[2] or by contact with contaminated faeces of cats[3]. All forms of *Toxoplasma* lose their infectivity quickly when exposed to the environment, with the exception of oocysts shed in feline faeces. These are remarkably resistant to ordinary environmental influences and can survive in most soil for several months[4]. In the acute phase of infection cats may shed several million oocysts in 1–2 weeks. It has been assumed that after the acute phase, chronically infected cats are safe as pets[5] since they have acquired immunity and oocysts seldom pass in the faeces[6–8]. I report here the reshedding of *T. gondii* oocysts by chronically infected cats in the absence of exogenous reinfection.

Twelve cats (four litters) were raised by their mothers from birth in my laboratory. Daily faecal examinations from birth did not reveal coccidian oocysts. Cats were weaned and bled for antibody determination at 83–106 d of age. Antibody to *Toxoplasma* was not detected in the sera of weaned cats by the Sabin–Feldman dye test. After weaning, all 12 cats were housed individually in stainless steel cages. Ten cats (nos 3–12) were fed 10[illegible] cysts of the M-7741 strain of *T. gondii* on day 0. Cats 1 and 2 were not fed *Toxoplasma* and served as controls. The faeces of all cats were examined daily for coccidian oocysts[9]. All 10 inoculated cats shed millions of *T. gondii* oocysts between 4 and 20 d after infection with *Toxoplasma* (Table 1). One cat (no. 7) reshed oocysts on day 28 after infection (Table 1). Three littermate cats (nos 9, 10, 12) spontaneously shed *Isospora felis* oocysts (Table 1). The remaining cats did not shed *I. felis* oocysts. The source of *I. felis* infection remained unknown.

To investigate interrelationships between *T. gondii* and other feline coccidia the animals were divided on day 30 after infection with *Toxoplasma* into two groups of six (*A* and *B*). Cats in group *A* (nos 1, 4, 6, 8, 10 and 11) were fed 10^4 sporulated oocysts of *I. rivolta* on day 30 after infection with *Toxoplasma* and 10^4 *I. felis* 13 d later. The effect of superinfection with *I. felis* and *I. rivolta* on established *Toxoplasma* infection seemed of particular significance in the light of Chessum's[10] report that a cat infected with *T. gondii* for 3 months started reshedding *Toxoplasma* oocysts 10 d after it was fed *I. felis* oocysts. *I. felis* and *I. rivolta* infections are asymptomatic in cats[11].

Both *I. rivolta* and *I. felis* caused patent infections in the inoculated cats. *I. rivolta* oocysts were shed between 6 and 12 d after *I. rivolta* was fed to the cats and *I. felis* were shed between 8 and 25 d after *I. felis* was fed to them. The cats in group *B* did not receive *I. felis* or *I. rivolta* and did not shed these organisms during this period. Four of five *Toxoplasma*-infected cats in group *A* reshed *T. gondii* oocysts beginning on day 10 after feeding with *I. felis* (or day 53 after infection with *Toxoplasma*); none reshed *I. rivolta*. Only one cat (no. 9) from group *B* reshed *T. gondii* oocysts during this period (Table 1).

On day 61 after infection with *Toxoplasma* cats in group *B* (nos 2, 3, 5, 7, 9 and 12) were fed 10^5 *I. felis* oocysts. All five *Toxoplasma*-infected cats (nos 3, 5, 7, 9 and 12) reshed *T. gondii* oocysts starting 9–14 d after feeding *I. felis* (Table 1). Cats 9 and 12 that were spontaneously infected with *I. felis* shed fewer *Toxoplasma* oocysts than did cats 3, 5 and 7 that were not previously infected with *I. felis*.

Overall, 9 of 10 cats reshed *Toxoplasma* oocysts. The reshed oocysts were identified as *T. gondii* by mouse to mouse passage.

Table 1 Shedding of *Toxoplasma* oocysts by cats with or without *I. rivolta* and *I felis* infection

Cat no.	Group	Primary Age of cats (d)	*Toxoplasma* infection Days oocysts shed	*Toxoplasma* infection No. of oocysts shed	*I. rivolta* fed PTID 30	*I. felis* fed PTID 43	Reshedding of *Toxoplasma* oocysts PTID oocysts shed	Reshedding of *Toxoplasma* oocysts No. of oocysts shed	*I. felis* fed PTID 61	Reshedding of *Toxoplasma* oocysts PTID oocysts shed	Reshedding of *Toxoplasma* oocysts oocysts shed

9†	B	83	4–11	$10^{7\ 14}$	No	No	31-33,50	10^4‡	Yes	75–76	10^4‡
10†	A	83	5–16	$10^{8\ 13}$	Yes	Yes	None		No	None	
11	A	83	4–14	$10^{7.43}$	Yes	Yes	53–64	$10^{6\ 17}$	No	None	
12†	B	83	4–15	$10^{7\ 15}$	No	No	None		Yes	72–77	$10^{5\ 21}$

PTID, post-*Toxoplasma* infection day All cats except nos. 1 and 2 were fed 10^5 cysts of the M-7741 strain of *T. gondii* on day 0. Faeces of cats in group *A* were examined for 1–74 PTID and of group *B* for 1–85 PTID. Littermates are bracketed together.

*Cats 1 and 2 remained free of *Toxoplasma* infection throughout the experiment.

†Spontaneously infected with *I. felis* (cat 9 shed *I. felis* on days 2, 3; cat 10 shed 25–34, cat 12 shed 2–4, 9–20 PTID).

‡Estimated number of oocysts in daily sample. Only one or few oocysts seen in faecal-float preparation.

Reshedding of *T. gondii* oocysts by 9 of 10 cats within a short time (9–14 d) after feeding *I. felis* suggests a reactivation of latent *Toxoplasma* infection, probably by interfering with immunity to toxoplasmosis in the feline intestine.

Between 20 and 64% of cats in several surveys contained antibody to *T. gondii*[12], indicative of exposure to the organism. Many of these cats are presumably permanent carriers of *Toxoplasma*. As *I. felis* is also a common parasite of cats the present findings may have a public health significance, especially in homes with pregnant women. It is sound advice for pregnant women to handle cat faeces with care irrespective of the *Toxoplasma* infection status of the cat[5].

Inheritance of susceptibility to *Trypanosoma cruzi* infection in *Rhodnius prolixus*

MILLIONS of cases of Chagas' disease exist in Central and South America[1]. Apart from being virtually incurable, a major problem in this disease is symptomless carriers harbour trypanosomes all their lives but it is often difficult to demonstrate the parasite[2]. At present, the simplest and most sensitive method of diagnosis[3] is to feed uninfected triatomine bugs on the suspected case and subsequently to examine a faecal sample from the bug for the presence of trypanosomes There is, however, great variation both within and between species of Triatominae, in their susceptibility to infection with *Trypanosoma cruzi* (see, for example, refs 4 and 5), and though a genetic basis for this variation in susceptibility has been suggested[4], it has not been verified. Obviously, the production of a highly susceptible strain of triatomine bug that would provide a quick and accurate diagnosis of chronic Chagas' disease would be a distinct advantage. I report here on the selection of both susceptible and refractory lines of *Rhodnius prolixus*, and the results of this selection programme are related to the genetic control of susceptibility to infection with *T. cruzi*.

Two strains of *T.cruzi* were chosen for their differing characteristics. The Peru strain was originally isolated in 1963 and after passage in mice was stabilated by cryopreservation[6]. This highly virulent strain has a prepatent period of 8–14 d in mice, and is lethal at 25–30 d following inoculation of more than 100 organisms[7]. In contrast, strain 7, isolated in Brazil in 1965 and stabilated after passage in mice, is of low virulence. This strain also has a pre-patent period of 8 d, but, unlike the Peru strain, parasitaemia declines about 30 d after inoculation, and the mice generally recover.

To study the effect of selection on susceptibility in *R.prolixus* over successive generations, a standard system was used to infect the bugs and, later, to measure the infection. TO mice were first used to provide a non-infecting feed, given 28 d before the infecting blood meal. Six- to eight-week-old male mice of the same strain were then infected with one or other strain of *T.cruzi* and used to feed the bugs which had moulted to fifth instar larvae. Feeding took place either 14 d after infection of the mice with the virulent Peru strain or 21 d after infection with the less virulent *T.cruzi* strain 7. In both cases the mice were checked for patent parasitaemia before feeding commenced. Bugs were kept individually in glass tubes and maintained in incubators at 28 °C and 70% relative humidity. Thirty five days after infection, adult bugs were again fed on clean mice, and faeces produced by the bugs within 1 h of feeding were collected in 0.2 ml Hanks solution. Bugs which did not feed were removed from the experiment. The number of trypanosomes excreted in a 20 μl sample of the mixed faecal–Hanks suspension was counted by systematically scanning 100 fields (×450). In the absence of detectable parasites, the bug was given a further clean feed 14 d later, and the second faecal sample was examined. If this was again negative, the remaining faecal suspension was injected intraperitoneally into a non-infected mouse, and blood samples examined 14 and 21 d later.

Where trypanosomes were seen at the first examination of faeces, the score represented the number counted in 100 fields If a bug showed no evidence of infection on all tests it was scored as zero, whereas if positive at either the second (faecal) or third (blood) test it was assigned an

Galaxy Formation
John Gribbin

A personal view of galaxy formation – a subject which holds a central place in modern astrophysics. The book reflects the author's own interests in this field, and thus offers a new and different perspective to a fascinating topic. Formal mathematics is kept to a minimum and the general level of the text makes it suitable for the second year physics students at university.

Contents: Stars and Galaxies-Cosmology · The Expanding Universe – The Traditional Approach: Turbulence and Gravitational Instability – Layzer's Gravitational Clustering Hypothesis – Ambartsumian's Fragmentation Hypothesis – Continual Creation – Newtonian Cosmology and Jean's Criterion – The Retarded Core Hypothesis – The Growth of Irregularities in an Expanding Universe – The Evolution of Galaxies – Our Galaxy – The Present Balance and Future Prospects.

We're old hands at new labelled compounds

We make about 70 new labelled compounds a year—covering all aspects of research. It's a long-standing, but very essential, development programme. We rely on our customers, our technical representatives and our own scientists, to tell us which compounds are needed for new scientific investigations.

Our current catalogue lists our labelled compounds but goes to press before new products are in production. We try to let customers know what's new—by advertising, mailing and representative calls. But if you still haven't heard the news, please write or 'phone for our new catalogue supplement. You may want to discuss your own ideas on new labelled compounds, and we'll be very happy to consider them. Meanwhile, we'd like you to consider ours.

arbitrary score of 1. In all, 1,725 bugs were reared, given an infecting feed, and scored in this way.

Selection was subsequently made from the two parental populations of bugs on the basis of individual faecal trypanosome scores. A single-pair full-sib mating system was followed for both groups of bugs, resulting in 19 F_2 families in the Peru strain group, while in the strain 7 group selection was carried one generation further to produce 17 F_3 families.

Results showed that selection did not significantly increase the proportion of refractory (score zero) bugs in lines selected for refractoriness. This suggests that refractoriness to infection with *T.cruzi* is not controlled by alleles at a single locus in *R prolixus*. By contrast, a quantitative analysis of faecal scores (transformed to a log $(n+1)$ scale), revealed that the intensity of infection sustained by individual bugs is a heritable characteristic. First, significant difference ($P<0.001$) were found between bugs of the same generation infected with the two different strains of *T.cruzi* Bugs fed on strain 7 infected mice were found to have a mean faecal score almost twice as high as that of bugs infected with the more virulent Peru strain. Clearly, strain differences affect the intensity of infection of individual bugs as well as affecting susceptibility rates[4,8] (that is, proportions of infected bugs in a population).

Further analysis of F_1 and F_2 families of *R.prolixus* infected with different strains of trypanosome showed significant differences in faecal scores between sexes ($P<0$ 001), when tested against the considerable variation between families. The same was true of F_3 families infected with strain 7. Control weighing experiments to determine any possible effect of variation in the size of blood meal or faecal sample were negative. There was no significant difference in blood-meal size between male and female fifth instar larvae, although it was interesting to note that adult females took significantly larger blood meals than males and also excreted a significantly greater proportion of their meals within 1 h of feeding. Thus, it might be anticipated that adult females would have higher scores than males, but that is not the case In fact, male scores were significantly greater than female scores in all generations tested. Miles *et al.* failed to detect such a sex-difference, but their conclusion was based on tests with a small number of bugs. Significant differences in faecal scores were also found between families of all generations infected with either strain of trypanosome, reflecting a resemblance between the intensity of infection of related bugs—one of the basic characteristics of metric traits[9].

Fig. 1 Response to two-way selection for intensity of infection with *T. cruzi* strain 7 in *R prolixus*. Cumulated selection differentials for each generation (weighted according to the number of progeny scored) are plotted against the response to selection derived from faecal scores transformed to log $(n+1)$ scale, sexes averaged Regressions, calculated from 4 high and 5 low selection lines, show the realised heritability to be 3 6 ± 1.1% for increases in intensity of infection and, for reductions in intensity of infection, 7.3 ± 0.9%. This asymmetric response is a common feature of two-way selection programmes[14] ●, F_1 family means; ▲, F_2 family means; ■, F_3 family means. *A*, $b = 0.0368\pm0\ 0115$, *B*, $b = -0.0731\pm0.0091$.

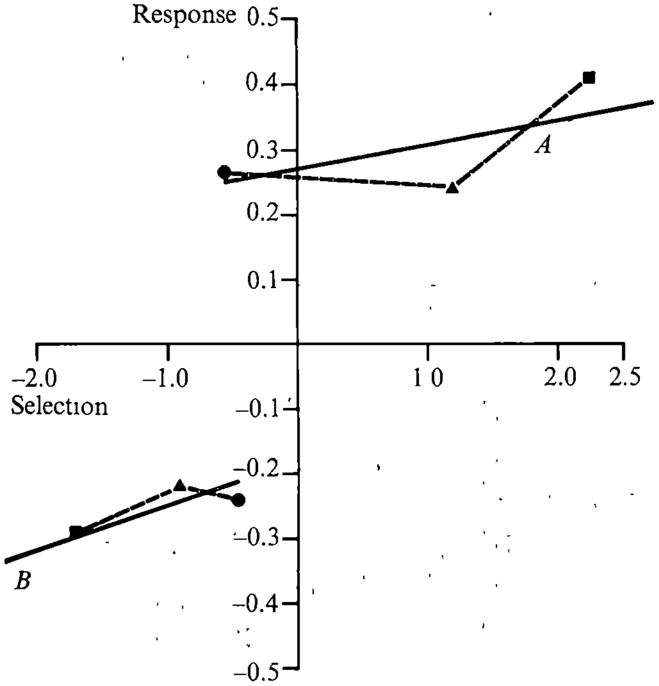

Figure 1 shows that selection for high and low levels of intensity of infection was successful. Analysis of F_3 family scores showed that differences between the selection lines were highly significant for both sexes ($P<0.001$) when tested against the variation between families within lines. The realised heritability of intensity of infection in *R.prolixus* was calculated from the regression of response (r) on selection differential (s)[10]. The regressions of both selection lines being highly significant ($P<0$ 001), the divergence of the two slopes provided an estimate of 5.5% for the heritability of this character. This low value relates to this laboratory colony and could differ for a natural population[9].

Knowledge of genetic mechanisms controlling the susceptibility of insect vectors to infection has so far been limited to mosquitoes and their malarial and filarial parasites, where to date only major gene control mechanisms have been demonstrated[11,12]. There have been attempts to quantify mosquito susceptibility to *Plasmodium gallinaceum* by counting oocysts[13], but significant parent–offspring regressions could not be shown. The present work has clearly shown that intensity of infection with *T.cruzi* in *R prolixus* is a metric character of low heritability, which is sex linked or at least sex limited. For the purposes of aiding the diagnosis of chronic Chagas' disease, it would be desirable to breed a colony of bugs that are highly susceptible to the multiplication of the few trypanosomes ingested from such patients. The present results indicate that using only male bugs of a susceptible stock for xenodiagnosis should enhance the sensitivity of this diagnostic test for chronic Chagas' disease.

I thank C. Constantinou for assistance, Dr D. S. Ketteridge for supply of trypanosomes and Professor D. S. Bertram for his encouragement. This work was financed by the Overseas Development Ministry.

Functional inactivation of suppressor T cells by heat-killed macrophages

We have shown that peritoneal exudate macrophages, killed by heating at 56 °C for 30 min, can markedly suppress the antibody response to heterologous erythrocytes in primary Mishell–Dutton cultures[1]. This heat treatment does not destroy the ability of the macrophages to form rosettes with sheep red blood cells (SRBCs) in the presence of cytophilic antibody, suggesting that some membrane surfaces remain undamaged. The heat treatment, however, does prevent the macrophages from excluding Trypan blue dye, indicating that the cells are no longer viable. Treatment of the macrophages at higher temperatures or with 0.1% glutaraldehyde destroys both their ability to form rosettes and to suppress Mishell–Dutton cultures. Macrophage membranes, semi-purified by separation on sucrose gradients, can act similarly—that is, suppress primary Mishell–Dutton cultures and form rosettes with SRBCs in the presence of cytophilic antibody (W.P. and R.K.G., unpublished). The heat-killed macrophages do not diminish the viability of the cell cultures even when they are maximally suppressive We have interpreted these results to indicate that the dead macrophages suppress the immune response in culture by absorbing out, and thus rendering inoperative, some factors which are necessary for the cell interactions which result in the generation of plaque-forming cells. This contention is supported by the ability of the heat-killed macrophages to absorb out the helper activity found in the supernatants of mixed lymphocyte reactions (W.P. and R.K.G., unpublished). We reasoned that, if macrophages could absorb interaction factors, they might be able to absorb suppressive factors if they were added to a culture in which suppression was occurring and thus augment the response of suppressed but not normal cultures.

We used a newly described *in vitro* technique to generate educated spleen cells with the capacity to specifically suppress the *in vitro* response to SRBCs (ref. 2). The suppression is mediated by T cells and is antigen-specific when less than 10^6 educated cells are added to spleen cell cultures. We cultured 10^7 BDF_1 spleen cells with 2×10^6 SRBCs according to the Mishell–Dutton technique. Four days later we retrieved the educated cells from culture and added different doses of them to new primary Mishell–Dutton cultures along with 2×10^6 SRBCs. Varying numbers of heat-killed macrophages were included in the second cultures which were incubated for a further 4 d before assay for plaque-forming cells. The results of one such experiment are presented in Fig. 1. The horizontal line represents the response of normal cultures without educated cells or macrophages. Addition of 10^5 educated cells to 10^7 normal spleen cells markedly suppressed the anti-SRBC response, whereas addition of 10^4 educated cells had no effect and served as a control for the effect of adding educated cells. The addition of 10^4 or 3×10^4 heat-killed macrophages to the suppressed cultures produced a moderate augmentation of the response, whereas it had no effect on the non-suppressed culture The addition of 6×10^4 or 10^5 macrophages to the suppressed cultures brought their response back to approximately normal levels Again this number of heat-killed macrophages had no effect on the non-suppressed response. Adding 3×10^5, 6×10^5 or 10^6 heat-killed macrophages suppressed the response in all cultures. Interestingly, increasing the macrophage dose beyond 3×10^5 or 6×10^5 cells did not increase the amount of suppression. This plateau effect is commonly seen (ref. 1 and W.P. and R.K.G., unpublished) and indicates that there is a base level of the immune response which the heat-killed macrophages cannot suppress; on the other hand, live macrophages can suppress the response to a 0 level

Thus, there seems to be a differential susceptibility of suppression and help to the effect of heat-killed macrophages. Low numbers of macrophages can preferentially abrogate suppression but cannot bring the response significantly higher than the normal response level. When the number of macrophages is high enough to suppress the control cultures, they also suppress the cultures which contain the suppressor cells, probably acting in the latter situation by interfering with help rather than by augmenting suppression. Whether these differential effects are due to different sensitivities of suppressor and helper factors, differences in their affinities for macrophage receptors or different numbers or types of receptors and/or macrophages is at present under investigation.

Since heat-killed peritoneal exudate macrophages do not augment primary Mishell–Dutton cultures at any dose, and can reverse suppression when known suppressor cells are added to the culture, as we have shown here, our results suggest that some mediators of suppression may have affinity for macrophage surfaces Heat-killed macrophages may prevent their interacting with their target cells by absorbing them from the culture. Of course, the vast body work of Feldmann[3] documenting the importance of the macrophage membrane as a site for lymphocyte interaction supports this contention.

Independent of the exact explanation for the phenomenon we have described, the results we have presented have practical as well as theoretical significance. They indicate that one can use this *in vitro* technique to determine whether a poor response is due to a lack of stimulation or to suppression. One can titrate in heat-killed macrophages and if these cells result in an increase of the response, one can be reasonably certain that the response of the test cells is due to alleviation of suppression. The heat-killed macrophages have no inherent augmentory capacity of their own. Note also that the failure of macrophages to augment a response cannot be taken as evidence that suppression is not present. We do not know whether, in other systems, one would find the differential susceptibility of suppression and help that we found in this system. We have found, however, that heat-killed macrophages can augment the generation of cytotoxic killer cells to syngeneic tumour

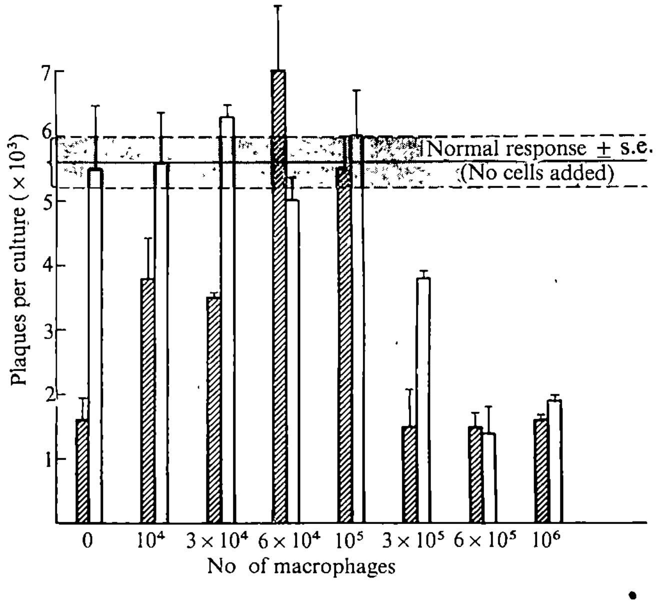

Fig. 1 Functional inactivation of suppressor cells by heat-killed macrophages. Educated cells were generated by culture of spleen cells *in vitro* with 2×10^6 SRBCs. The normal response to SRBCs of the assay cultures (horizontal line) was suppressed by 10^5 educated cells (hatched columns), whereas 10^4 educated cells (open columns) induced no suppression and served as the control. Increasing numbers of heat-killed macrophages were added to the suppressed or control cultures.

cells *in vitro* (C. Metzler, W.P. and R K.G., unpublished), suggesting that the generation of suppressor cells is one of the factors contributing to the difficulty in getting a good killer-cell response against tumour cells *in vitro*. In any case, the ability to use heat-killed macrophages in *in vitro* responses to document the presence of suppression in the cultures should be of help in dissecting out some of the complicated interactions between subpopulations of lymphocytes which control the immune response.

Onset of acetylcholine sensitivity and endplate activity in developing myotome muscles of *Xenopus*

THE distribution of acetylcholine receptors and the onset of functional innervation at the neuromuscular junction during development have been much investigated[1–3], as have the events during regeneration and reinnervation of muscle[4]. Although the first appearance of acetylcholine (ACh) sensitivity of the membrane has been charted in chick and mouse myoblasts differentiating in tissue culture[5], previous studies *in vivo* have either not tested for the initial appearance of ACh sensitivity[2], or found the muscle membrane to be already sensitive to externally applied ACh[1]. In the present study on *Xenopus* embryos we have followed the initial appearance of membrane depolarisation in response to applied ACh and the onset of functional innervation in differentiating myotome muscle *in vivo*.

Myotome formation from the presumptive mesoderm begins before the neural tube closes (stage 17)[6], and continues up to late swimming stages Figure 1 shows the arrangement of cells in the presumptive mesoderm and the fully formed myotomes described by Hamilton[7]; a new myotome is formed about every 20 min. The myotomes are innervated segmentally by cells in the ventrolateral part of the neural tube[7,8]. Innervation, like myotome formation, begins at the head end and proceeds tailwards. Flexions of the body first occurred between stages 21 (8 somites) and 24 (12–15 somites), the precise time varying between clutches of eggs.

Membrane potentials were recorded with microelectrodes filled with 0.8 M potassium citrate (resistance >100 M; tip potential < −8 mV). Embryos (stages 19 to 25) were pinned out in a small bath and superfused with Ringer solution (NaCl, 120 mM; KCl, 2.5 mM; $CaCl_2$, 2 mM; Tris, 2 mM; *p*H 7.4). The ectoderm was peeled away and the dermatome layer of the mesoderm left intact above the myotomes. The microelectrode was pushed through the dermatome into the muscle cells. Because cells in the myotome have membrane potentials 40 mV greater than those of the dermatome[10] and because the two cell layers are not electrically coupled to each other[10], the position of the microelectrode was never in doubt.

Figure 2 shows records taken in 1 of 37 experiments to test for acetylcholine sensitivity of the muscle membrane. The microelectrode was inserted while an embryo at stage 21 was superfused with Ringer solution. At 10-min intervals the bathing fluid was changed to Ringer containing 10^{-4} g ml^{-1} ACh, which should produce a maximal response; if no depolarisation had resulted after several minutes, Ringer solution was readmitted. Figure 2*a* illustrates the last test in which ACh was without effect, suggesting that the membrane did not yet contain functional ACh receptors. Figure 2*b* shows the prompt and rapid depolarisation of 44 mV produced by admission of ACh 9 min later. Subsequent tests gave depolarisations of similar time course and magnitude. The results of this and eight other experiments with test intervals of between 10 and 30 min suggest that ACh receptors become functional relatively quickly. On all occasions the first depolarisation produced by ACh was as great as that produced by subsequent tests, suggesting that the response is immediately established at its maximum level. In 23 other experiments ACh sensitivity was already present when testing began.

The depolarisation in response to bath-applied ACh was always relatively prompt and brought the membrane potential to between −12 and −5 mV, close to the value recorded in adult amphibian muscle, suggesting that the reversal potential, and therefore the underlying permeability changes, are the same as in adult muscle[11].

After the appearance of ACh receptors, random deflections of the membrane potential were recorded, indicating that spontaneous liberation of ACh from innervating motor nerves had begun. The interval between these two events was variable, ranging from 15 min to about 1 h; once endplate activity could be recorded, bath application of ACh always produced depolarisation. The initial potentials were small, possibly miniature endplate potentials produced by spontaneous release of ACh without electrical activity in the nerve. A period when extremely large spontaneous depolarisations (up to 60 mV) were recorded invariably followed. Figure 2*c* shows a pen record of such activity to-

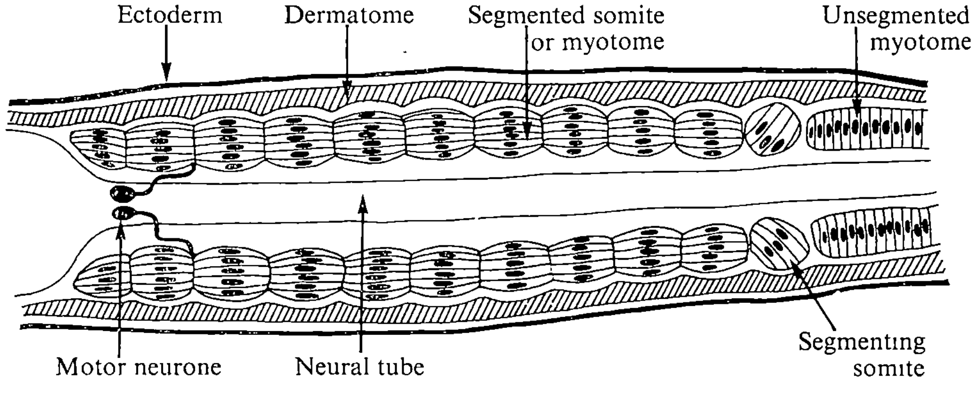

Fig. 1 Diagram of horizontal section through 10 somite *Xenopus* embryo to show arrangement of myotome cells

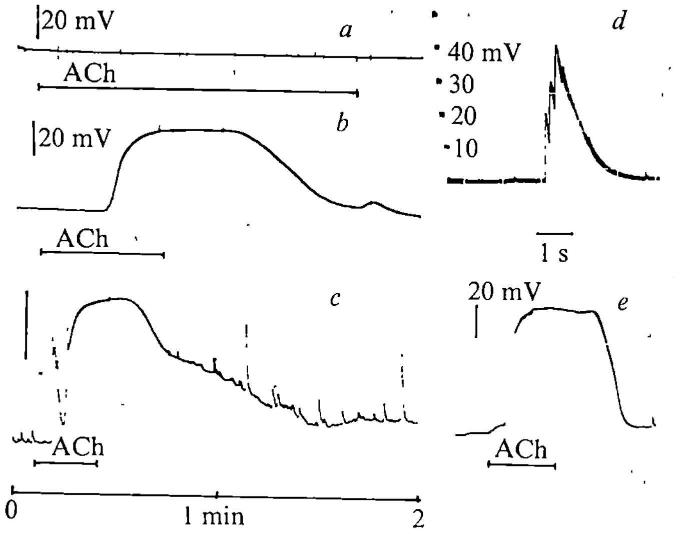
gether with the depolarisation produced by superfusion with ACh. A high gain oscilloscope record (Fig. 2*d*) shows these large depolarisations to take the form of summated endplate potentials. This activity seems most likely to be the consequence of action potentials in the motor nerve since very large miniature endplate potentials are not normally seen in developing neuromuscular junctions[1], and the input resistance of the electrically coupled muscle fibres is not particularly high. Both the spontaneous activity and the response to ACh were blocked by curare. Because electrical coupling between the muscle fibres is good[10], it was not possible to distinguish how many motor nerves contributed to the recorded spontaneous activity. Direct nerve stimulation is not possible in this preparation. Mn^{2+} abolished the endplate potentials, but not the response to perfusion with ACh. Figure 2*e* illustrates the ACh depolarisation in a preparation made silent by the addition of 2 mM Mn^{2+} to the bathing fluid.

Muscle action potentials were sometimes recorded before any visible endplate activity, although they usually appeared after spontaneous liberation of acetylcholine from the nerve had begun. In spite of high resting membrane potential, the earliest action potentials did not initiate muscle contraction, which was never seen before spontaneous endplate activity could be recorded. These findings make the suggestion that early flexions *Xenopus* embryos are myogenic in origin[9] extremely unlikely. It seems more probable that early movements are initiated by discharge from the motor nerves and achieved by transmission of the depolarisation from one myotome to the next along the low resistance intercellular pathway, as described by Blackshaw and Warner[10].

These experiments show that formation of the first functional neuromuscular junctions in *Xenopus* takes place between segmentation of the fourth and fifteenth myotome. The sequence of events is summarised in Fig. 3, where the appearance of functional ACh receptors has been put at stage 21½, with flexions beginning at stage 24 (about 2 h later). The onset of this sequence varied from clutch to clutch so that receptor appearance could occur as early as stage 19 with flexions following 2 h later at stage 21. On occasion however, the whole sequence from the appearance of ACh sensitivity was compressed into as little as 0.5 h. Thus both the timing of the initial insertion of ACh receptors and the length of time taken to establish functionally innervated, contracting muscle showed considerable variation from embryo to embryo. This implies that the development programme does not specify a precisely interrelated timing schedule for this sequence, suggesting that each event is to some extent independent.

Fig. 2 Membrane potential records taken during tests for acetylcholine sensitivity of myotome muscle membrane. *a*, Embryo stage 21 · 10^{-4} g ml^{-1} ACh has no effect on the resting potential of a myotome muscle cell. $E_m = -70$ mV *b*, Same embryo 9 min later: 10^{-4} g ml^{-1} ACh now produces large depolarisation. *c*, Embryo stage 24: spontaneous depolarising activity in muscle cell together with response to 10^{-4} g ml^{-1} ACh. $E_m = -75$ mV. *d*, Oscilloscope record to show spontaneous activity takes the form of summated endplate potentials. Note two miniature e p.p.s on rest of trace. Stage 23: *e*, Depolarisation produced by 10^{-4} g ml^{-1} ACh in preparation made silent by addition of 2 mM Mn^{2+} to the bathing fluid.



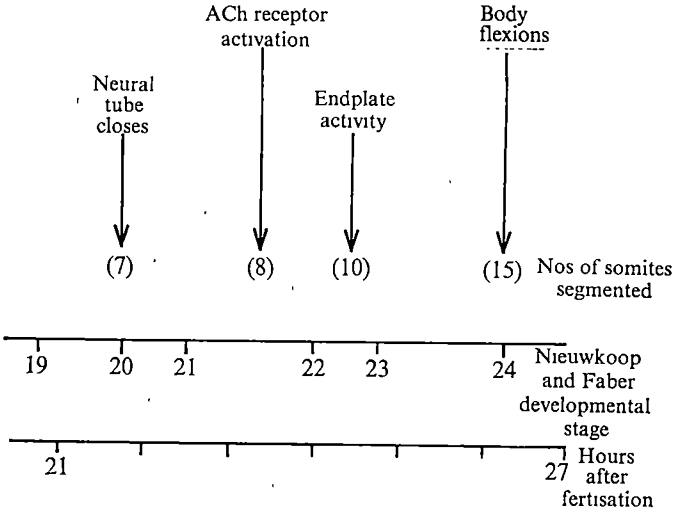


Fig. 3 Diagram to show sequence of events during differentiation of functional neuromuscular junctions in myotome muscle of *Xenopus*. Action potential generation in the muscle membrane may appear anywhere between stages 19 and 23.

The abrupt initial appearance of functional ACh receptors and the speed of subsequent events culminating in the establishment of the first neuromuscular junction, seems, at first sight, surprising. The overall speed of development of *Xenopus*, however, which moves from fertilised egg to flexing tadpole in only 27 h, makes a fast rate of this, and all other developmental sequences, inevitable.

The appearance of spontaneous endplate potentials could mark the time when the nerve ending first makes contact with the muscle. On that view acetylcholine sensitivity in the muscle membrane is established some time before the arrival of the nerve ending and could, therefore, serve in some way to guide the nerve to its final destination. The results are equally compatible with the view that the release of ACh does not begin until some time after the arrival of the nerve, functional connection being a relatively late event in the formation of the neuromuscular junction. Detailed anatomical studies, correlated with electrophysiological studies of the kind described here, might enable this point to be resolved.

We thank the MRC for support.

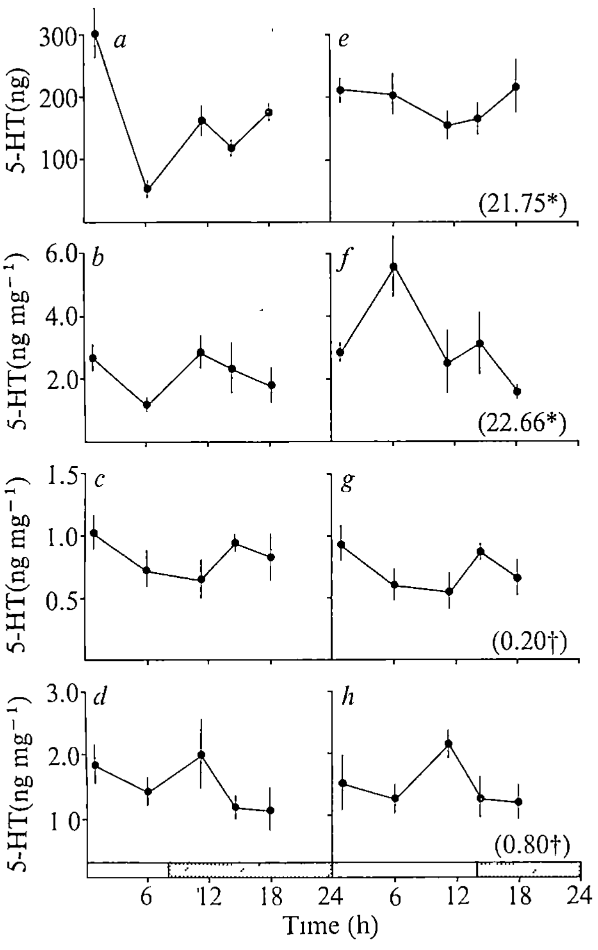
Differential circadian rhythms in pineal and hypothalamic 5-HT induced by artificial photoperiods or melatonin

CHANGES in daylength are principally responsible for synchronising breeding with time of year in mammals and birds[1]: for example, ferrets begin to breed in spring and oestrus ends in autumn. Oestrus can be provoked by exposure to long photoperiods (such as 14 h light: 10 h dark, LD 14 : 10) during winter[2] and can be terminated prematurely if short photoperiods (LD 8 : 16) are given during summer[3]. The pineal is essential for both effects, which are prevented by removal of the gland[3,4] or its autonomic nerve supply[5] from the superior cervical ganglia (C.A.Y. unpublished results). The pineal contains large concentrations of the transmitter 5-hydroxytryptamine (5-HT), which has been implicated in the neural control of circadian rhythms, which themselves may be related to the genesis of annual rhythms[1]. In the pineal of the rat concentrations of 5-HT vary in phase with photoperiod, and this rhythm is prevented by ganglionectomy[6]. Inhibition of cerebral 5-HT synthesis prevents circadian rhythms in concentrations of both plasma adrenal corticosteroids[7] and luteinising hormone[8]. Lesions of the suprachiasmatic nuclei, which contain large concentrations of 5-HT[9,10], abolish circadian rhythms in eating and drinking[11], in running[12] and in concentrations of pineal *n*-acetyltransferase[13], which is the rate limiting enzyme in the synthesis of melatonin, a putative pineal hormone. The pineal must transmit information about photoperiod to neural structures regulating the pituitary, but the nature of the link is unknown. We report here that exposure of ferrets to either long or short photoperiods induces differential 5-HT rhythms in the pineal and hypothalamus, which are abolished by autonomic denervation, and that melatonin induces 5-HT rhythms characteristic of animals kept in short photoperiods.

Fig. 1 Circadian rhythms in 5-HT concentrations in various areas of brain, from ferrets kept for 8 weeks in either short (LD 8 : 16) (*a–d*), or long (LD 14 : 10) (*e–f*) days. *a*, *e*, Pineal gland; *b*, *f*, hypothalamus; *c*, *g*, midbrain; *d*, *h*, cerebral cortex. Levels in the hippocampus (not shown) were similar to those in the cerebral cortex. Five or six animals were killed by decapitation 30 min, 6, 11, 14 and 18 h after the lights came on 5-HT levels in the pineal, whole hypothalamus, midbrain and in samples from ventral hippocampus and dorsal cerebral cortex were measured fluorometrically[22]. Each point is the mean ±s.d in ng per mg wet tissue, except in the pineal (ng per gland) which weighs about 1 mg The hatched areas signify the dark part of the photoperiod. The figure in parentheses is the *F* ratio of the interaction (light treatment × time of day) derived from a two-way analysis of variance. $^*P<0.001$; †Not significant.



In the first experiment, mature female ferrets were exposed to either long (LD 14 : 10) or short (LD 8 : 16) photoperiods for 8 weeks, the interval required to activate or inhibit oestrus[3,4]. The ovaries were removed to prevent long days from selectively inducing oestrogen secretion. Illumination was from fluorescent tubes with a spectral output similar to that of daylight; feeding times and temperature fluctuations were similar under long and short photoperiods.

Figure 1 (*a–d*) shows that the circadian rhythm in 5-HT was similar in each brain area examined from animals kept in short photoperiods in spite of considerable differences between them in absolute values. Levels declined during the first 6 h of the photoperiod, rising again during the early part of the dark phase. In long photoperiods, however, the rhythm was different in the pineal and the hypothalamus (Fig. 1*e* and *f*). The rhythm in the pineal was attenuated, and this apparent difference was confirmed by a significant interaction between light treatment and time of day. There was also a striking difference in the 5-HT rhythms in the hypothalamus, levels rising during the first 6 h of the long photoperiod, the opposite of the situation observed during short days.

Circadian changes in 5-HT in midbrain, cerebral cortex and hippocampus appeared to be similar in long and short photoperiods (Fig. 1*g* and *h*) and there was no significant effect attributable to the interaction between the light regimes and time of day in these areas. Thus, two structures (pineal and hypothalamus) known to be concerned with the initiation of oestrus by long photoperiods show distinctive rhythms of 5-HT concentration in this condition, whereas the other areas examined do not.

In the second experiment, the preganglionic fibres to the superior cervical ganglia were severed (decentralised) 5–6 d before the animals were exposed to long or short photoperiods as in the first experiment. Figure 2 shows that circadian 5-HT levels were now similar in both photoperiods, and that those in either the pineal or the hypothalamus no longer exhibited a significant interaction between light treatment and time of day (Fig. 2*c* and *d*). The midbrain, cerebral cortex or hippocampus again showed no differential effects of light, as in the first experiment. The standard deviations of each point in Fig. 2 are conspicuously larger than those in Fig 1, suggesting that the 5-HT rhythms of decentralised animals might have been "free running", though this conclusion cannot be substantiated on the evidence presented here. Thus, a procedure which prevents the reproductive system of the ferret from responding to either long or short days also prevents the differential effects of the two photoperiods on 5-HT levels in the pineal and the hypothalamus.

Melatonin has been shown to affect cerebral 5-HT levels in rats. Injected 8 h after the onset of a photoperiod (LD 14 : 10), it abolished the circadian rhythm in pineal 5-HT, whereas treatment at 14 h was ineffective[14]. It may also increase hypothalamic and midbrain 5-HT levels[15]. Melatonin also replicates at least three of the effects of short photoperiods on the ferret's reproductive system, since it terminates the breeding season prematurely[3], antagonises the effects of long photoperiods on the initiation of oestrus[16] and restores photosensitivity to ferrets made photorefractory by prolonged exposure to long days[3]. In

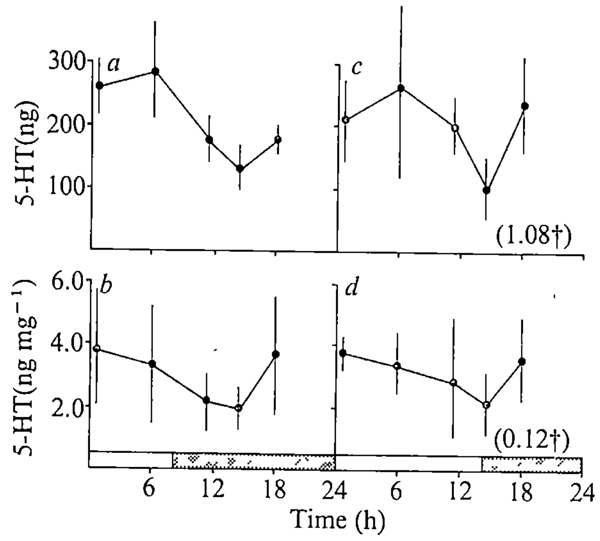


Fig. 2 Levels of 5-HT in the pineal (*a*, *c*) and hypothalamus (*b*, *d*) of ferrets kept in short (*a*, *b*) or long (*c*, *d*) photoperiods, after bilateral "decentralisation" of the superior cervical ganglia See Fig. 1 for further details.

the third experiment, therefore, two groups of ovariectomised ferrets were exposed to long photoperiods. The first received melatonin (1 mg d^{-1}) dissolved in arachis oil for 8 weeks, the second, control injections of oil. Injections were given 8 h after the onset of light, a time corresponding to the start of the dark phase in the short daylight regime used in the previous two experiments. Melatonin synthesis, in rats at least[17], seems to be accelerated during this dark phase. Figure 3*a* and *b* shows that melatonin given in this way to animals exposed to long photoperiods caused 5-HT rhythms in both pineal and hypothalamus characteristic of ferrets kept in short-days in the first experiment. Control injected animals (Fig. 3*c* and *d*) showed the rhythms expected for long-day conditions. Thus, a treatment which replicates some of the actions of short days on reproduction in ferrets also reconstitutes the short-day 5-HT rhythms in the pineal and the hypothalamus. The site at which melatonin acts to produce such effects in the ferret cannot be determined from these experiments.

We do not know whether the 5-HT rhythms reported here are directly concerned with reproduction, although 5-HT infused into the cerebral ventricles can alter gonadotropin secretion in rats[18] and sheep[19]. If they are, they might represent the neural basis for a variation on the Bunning hypothesis[20] which suggests that different photoperiods could shift the circadian photosensitive phase[21]. It seems equally possible that localised 5-HT rhythms may reflect part of the process which promotes or inhibits hypothalamic mechanisms concerned with gonadotropin secretion in appropriate environmental conditions. The latter interpretation receives some support from other (unpublished) experiments by us showing that oestrogen treatment, which presumably activates negative feedback mechanisms on the pituitary, attenuates 5-HT rhythms in both pineal and hypothalamus in either long or short day conditions. Whatever the interpretation, differential 5-HT rhythms in the pineal and hypothalamus could allow the animal's neuroendocrine system to discriminate between photoperiods which have the greatest significance for its reproductive function.

Fig. 3 Levels of 5-HT in the pineal gland (*a*, *c*) and hypothalamus (*b*, *d*) of ferrets kept in long photoperiods, given either 1 mg d^{-1} of melatonin (*a*, *b*) or arachis oil (*c*, *d*) 8 h after the start of the photoperiod (the time of injection is shown by arrows). See Fig. 1 for further details.

Muscarinic agonists provide a new class of acaricide

THE resistance of ticks to chemical methods of control is an increasingly serious problem[1–5], and new classes of compounds with high acaricidal activity and low mammalian toxicity are needed urgently. In the search for novel acaricides the nervous system is a prime target, and, in spite of evidence about the role of γ-aminobutyrate and glutamate in arthropod nervous transmission, acetylcholine is the only well established neurotransmitter[6–9]. So far only acetylcholinesterases have achieved an important role in the disruption of cholinergic neurotransmission. Anticholinergics, such as atropine, are ineffective, and cholinomimetics other than nicotine have been little investigated. We now report that certain muscarinic agonists are potent acaricides.

Known muscarinic agonists were tested for activity against the tick *Boophilus microplus*, using a strain resistant to organophosphorous insecticides (Biarra), and a susceptible strain (Yeerongpilly). Engorged females (2×6) were dipped in a solution of the test compound in methanol–acetone (1 : 1), dried on filter paper, and stored in vials for 4 weeks at 25 °C and 85% relative humidity. The concentration of compound required to prevent the production of viable eggs was taken to be the LC_{100}. The results are shown in Table 1, along with those for nicotine and the organophosphorous insecticide pyrimithate (Diothyl, ICI) as references. No significant differences were observed between results for Yeerongpilly and Biarra strains for the cholinomimetics, but pyrimithate was inactive against the latter.

The ixodicidal activity of the muscarinic agonists examined parallels to a large extent the activity observed in vertebrate systems. Thus arecoline and pilocarpine have a similar level of activity (on a weight basis) and are considerably less potent than oxotremorine[10]. Similarly compound 7, which has 10–20% of the activity of oxotremorine in vertebrate systems[11,12], is about 20% as active against ticks. Quaternisation of the nitrogen atom generally caused a marked decrease in ixodicidal activity, possibly due to poorer penetration, since compound 8, for example, is more active than the tertiary-amino compound (7) in vertebrates[11,13], although the methiodides of arecoline and oxotremorine are reported to be less active than the tertiary amines[10]. Tremorine, which is oxidised *in vivo* to oxotre-

Table 1 The toxicity of muscarinic agonists to *Boophilus microplus* (Yeerongpilly strain)

Compound no	Name	Structure	LC_{100} (% × 10^2)
1	Arecoline		50
2	Arecoline methiodide		50
3	Pilocarpine		50
4	Oxotremorine		1
5	Oxotremorine methiodide		50
6	Tremorine		100
7	1-(4-Dimethylaminobut-2-ynyl) pyrrolid-2-one		5
8	1-(4-Dimethylaminobut-2-ynyl) pyrrolid-2-one methiodide		50
9	Pyrimithate		5–10
10	Nicotine		10–20

morine by mammals[14], showed only slight activity against ticks.

It is interesting that oxotremorine is considerably more potent than both nicotine and the reference organophosphorous compound. The cholinomimetics also showed activity against mites, but were completely inactive against *Musca domestica* (adults), *Aedes aegypti* (larvae), and *Lucilia pericata* (larvae). Further work is required to determine whether this difference between Insecta and Acarina is morphological or biochemical in origin.

In conclusion, the muscarinic agonists examined are acaricidal, and in some cases are highly potent. We suggest that this unexploited biochemical lesion may provide a useful starting point for the design of new acaricides.

We thank Dr F. S. Downing for the routine screening of compounds.

Transmission without spikes between locust interneurones and motoneurones

MANY neurones, particularly in sensory systems of both vertebrates and invertebrates, do not produce action potentials[1–3]. In motor pathways within the central nervous system of arthropods there are interneurones whose slow changes in membrane potential can affect the frequency of action potentials in motoneurones[4–6]. Some of these interneurones normally produce spikes[6], but others apparently do not[4,5]. We have studied the properties of synaptic transmission between these non-spiking interneurones and motoneurones in the locust, *Schistocera gregaria*, in the course of investigating the integrative mechanisms underlying the generation of motor patterns[7].

Intracellular recordings were made in the metathoracic ganglion[8] from dorsally located somata of hindwing and hindleg motoneurones, identified physiologically by simultaneous extracellular recordings from appropriate muscles. Each motoneurone was individually identified so that intracellular recordings could be made from the same neurone in different locusts. Non-spiking neurones were penetrated intracellularly in the dorsal neuropile close to the neuropilar processes of the motoneurones. Most recordings were made with electrodes filled with potassium acetate but some were made with electrodes filled with cobaltous chloride[9] to allow the subsequent staining of the motoneurones and non-spiking neurones (Fig. 1). The non-spiking neurones have profuse arborisations within the metathoracic ganglion, but have no projections to other ganglia, nor any processes emerging in peripheral nerves; hence they are intraganglionic interneurones.

In a quiescent locust these interneurones are modulated

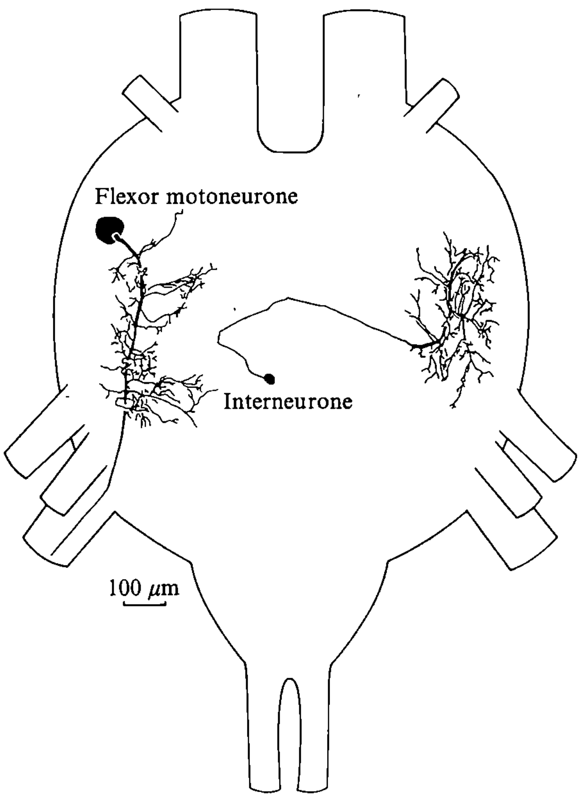

Fig. 1 Drawings of an interneurone and a motoneurone stained by intracellular injection of cobalt as viewed dorsally in a whole mount preparation of the metathoracic ganglion. The neurones were filled on the same side in different locusts but for clarity are drawn on opposite sides of the same ganglion. Left, the lateral fast flexor motoneurone of the left hind tibia whose soma is on the dorsal surface of the ganglion; right, an interneurone whose soma is ventral, which when depolarised resulted in a depolarisation of this flexor motoneurone. The extensive arborisations of the two neurones overlap in all three dimensions.

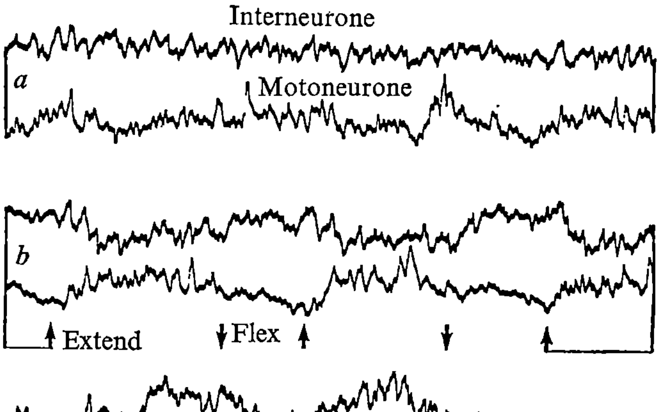

Fig. 2 Spontaneous and evoked sequences of synaptic potentials in a fast motoneurone innervating the flexor tibiae of the hind leg (lower traces) and in a presynaptic non-spiking interneurone (upper traces). *a*, In a quiescent locust both the interneurone and the motoneurone are modulated by a steady stream of synaptic potentials. *b*, Imposed extensions of the tibia of the hind leg, beginning at the upward arrows, result in a depolarisation of the motoneurone and a hyperpolarisation of the interneurone. *c*, Flexions of the tibia evoked by touching the head are accompanied by a depolarisation of the interneurone. Potentials of the flexor tibiae muscle are monitored extracellularly on the third trace.

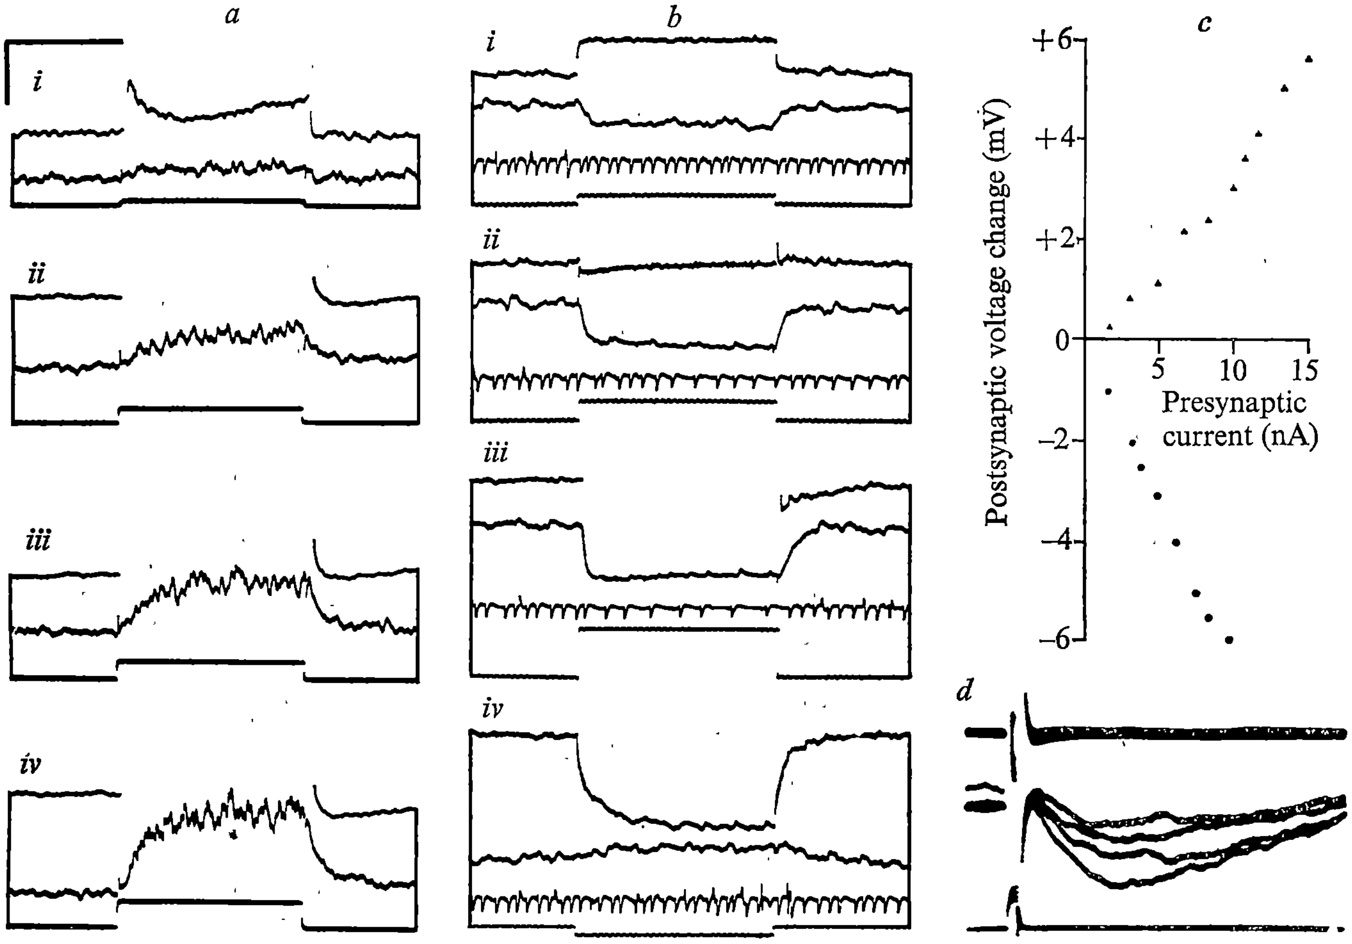
by a steady stream of synaptic potentials, but do not spike (Fig. 2*a*). Imposed or evoked movements of the joint whose motor units they affect result in changes in the membrane potential of the interneurone (Fig. 2*b* and *c*). The interneurones do not spike, either as a result of synaptically driven depolarisations, or in response to an injected depolarising current as high as 50 nA. This current strength is at least ten times that needed to evoke spikes when injected into the neuropilar segment of a motoneurone. Currents as low as 2 nA injected into an interneurone result in a change in the membrane potential of motoneurones.

We have observed three effects on motoneurones of passing current into interneurones: first, an applied depolarisation of an interneurone results in the depolarisation of a motoneurone (Fig. 3*a*, i–iv); second, a depolarisation results in the hyperpolarisation of a motoneurone (Fig. 3*b*, i–iii); third, in some interneurones that produce the second effect, hyperpolarisation results in the depolarisation of the motoneurone (Fig. 3*b*, iv). Single interneurones have postsynaptic effects upon more than one motoneurone, as revealed by changes in the frequency of extracellularly recorded potentials in muscles innervated by other motoneurones (Fig. 3*b*).

The following analysis is concerned with the properties of transmission between interneurones and motoneurones when an interneurone is depolarised. Transmission is graded. A pulse of curent lasting a few hundred ms injected into an interneurone results in a slow change in the membrane potential of the motoneurone. There is no effect on the motoneurone if the same amount of current is passed when the electrode is just outside the interneurone. With intracellular stimulation of the interneurone, the amplitude of the slow change is linearly related to the magnitude of the depolarising current over the range tested (Fig. 3*c*). At higher current strengths the postsynaptic depolarisations can be large enough to evoke action potentials in the motoneurones. Brief pulses injected into an interneurone result in changes in the membrane potential of the motoneurone, which vary continuously with the strength of the applied current (Fig. 3*d*) At no time during brief stimulation of the interneurone does the membrane potential of the motoneurone change abruptly as would be expected if the interneurone itself, or an intervening interneurone, had spiked.

Fig. 3 Effects of non-spiking interneurones (first traces) upon a fast motoneurone (second traces) innervating a bifunctional muscle, the tergotrochanteral. This muscle elevates the hind wing in flight and depresses the trochanter of the hind leg in walking. *a*, *i–iv*, An interneurone which when depolarised results in a graded depolarisation of the motoneurone in a ganglion with all peripheral nerves cut. Current (third traces) was injected through the high resistance recording electrodes by means of a bridge circuit which was out of balance except at the lowest current strengths. *b*, A second interneurone in another locust affecting the same tergotrochanteral motoneurone: *i–iii*, depolarisation results in a graded hyperpolarisation of the motoneurone; *iv*, hyperpolarisation of the interneurone results in a slight depolarisation of the motoneurone which presumably indicates a decreased rate of release of transmitter. The third traces monitor the extracellular potentials of some coxal muscles of the hind leg whose motoneurones are also affected by this interneurone; the downward deflections are from the anterior adductor of the coxa, whose potentials are reduced in frequency when the interneurone is depolarised; the upward deflections are from another coxal muscle that is excited when the interneurone is hyperpolarised. The fourth traces monitor current. *c*, The graded nature of the transmission between the interneurones and the tergotrochanteral motoneurone is indicated by the relationship between presynaptic current and the change in postsynaptic voltage. Triangles are measurements taken from records of the interneurone–motoneurone pair shown in *a*; circles are from the pair shown in *b*. The voltage of the motoneurone was measured 300 ms after the onset of the stimulus. *d*, 1.5-ms current pulses of increasing strengths injected into the interneurone shown in *b* result in graded changes in voltage in the motoneurone. Calibration—Voltage: *a*, motoneurone 3.8 mV, interneurone 20 mV; *b*, motoneurone 7.7 mV, interneurone 20 mV; *d*, motoneurone 1.5 mV; interneurone 15 mV: current: *a*, 33 nA; *b*, 17 nA; *c*, 75 nA. Horizontal: *a*, *b*, 400 ms; *d*, 14.5 ms.



SCIENCE COLLEGE
Upper Circular Road

The most economical interpretation of the graded effect is that the interneurones synapse directly upon the motoneurones. The synaptic delay cannot be measured accurately because transmission is graded. Pulses (1 ms) of current injected into an interneurone are followed within 1 ms by a voltage change in the motoneurone, a delay similar to that observed between spiking interneurones and leg motoneurones of the locust. The gross anatomy is consistent with a monosynaptic connection because there is considerable spatial overlap in the neuropile of the fine branches of an interneurone and a motoneurone upon which it exerts an effect (Fig. 1).

The connections between the interneurones and motoneurones that we have encountered so far, seem to be chemically and not electrically mediated, for the following reasons. First, current of either polarity injected into a motoneurone has no effect upon the membrane potential of the presynaptic interneurone. Spikes in the motoneurone are not reflected in the interneurone. Second, a brief square wave depolarising pulse injected into an interneurone decays rapidly, but evokes a potential in the motoneurone that can persist for 45 ms (Fig. 3*d*). This prolonged effect is probably the result of transmitter release from the interneurone. It is not the result of passively charging the motoneurone through an electrical synapse, because the postsynaptic potential reaches its peak some 10 ms after the end of the stimulus, and is asymmetrical. Third, in those interneurones where depolarisation results in the hyperpolarisation of a motoneurone, the reversal of sign is most easily explained by supposing that the depolarisation increases the rate of release of a transmitter substance that has an inhibitory effect upon the motoneurone. Fourth, there is often a progressive increase in the transmembrane voltage fluctuations recorded in a motoneurone as it is depolarised by increasing amounts of current injected into an interneurone (Fig. 3*a*). Increased fluctuations of voltage have not been observed when a motoneurone is hyperpolarised by depolarisation of an interneurone. This is a consistent observation but we have no evidence which would favour one of many possible explanations. Current injected directly into the motoneurone, causing a similar shift of its membrane potential, does not give rise to an increase in the fluctuations of the transmembrane potential. The increased fluctuations in voltage on depolarisation can therefore be attributed to synaptic transmission. They are not caused by spikes in sensory feedback loops, as they are still recorded in a ganglion with all its peripheral nerves cut. There remain two possible explanations as to their origin. First, the interneurone has a direct connection with the motoneurone, but also excites spiking interneurones that in turn synapse on the motoneurone. This possibility of parallel pathways cannot yet be eliminated. Second, the voltage fluctuations could result from the release of transmitter from the interneurone directly on the motoneurone. This may be the only mechanism or it may operate in conjunction with the first mechanism. The effect is similar to that seen in a frog muscle fibre when the terminals of its motoneurone are depolarised by pulses of current which do not evoke action potentials[10]. At the frog neuromuscular junction the voltage fluctuations result from the random release of transmitter substance and a similar explanation may be appropriate for the non-spiking interneurones of the locust. We conclude that the non-spiking intraganglionic interneurones modulate the membrane potential of motoneurones by graded release of transmitter through monosynaptic pathways.

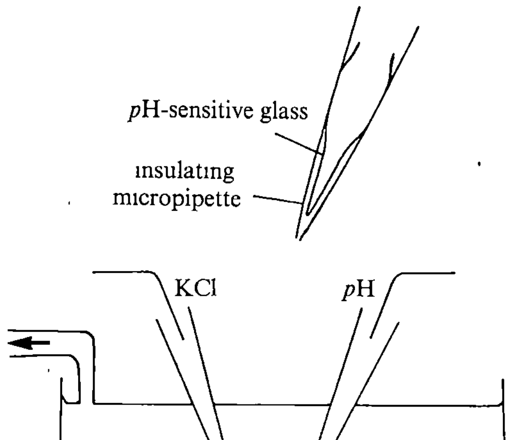
Microelectrode measurement of the intracellular *p*H of mammalian heart cells

RECESSED-TIP *p*H-sensitive microelectrodes[1] can be made sharp enough to be used on mammalian muscle cells. They permit not only the direct measurement of the intracellular *p*H (*p*H$_i$), but also the continuous recording of changes in *p*H$_i$ during experiments lasting for several hours. We report here the first measurements of the *p*H$_i$ of mammalian cardiac tissue made with this type of *p*H-sensitive microelectrode. Apart from one report of experiments with an open-tipped microelectrode[2], the only previous determinations of cardiac *p*H$_i$ have been made by the CO_2 or DMO methods[3], which are indirect and can detect only very slow changes. Earlier designs of *p*H-sensitive glass microelectrodes have been of little use because of their large size. The recessed-tip design (Fig. 1) lacks this drawback, as only its extreme tip, which can be as small as 0.5 μm in diameter, needs to be inside the cell. We have used these electrodes successfully in ventricular muscle preparations from several animals, but the results described here are confined to those obtained with sheep heart Purkinje fibres.

Our experimental arrangement is illustrated in Fig. 1. Free-running single Purkinje fibres were cut from sheep ventricles. A little side wall material was left attached to pin the fibre in the perfusion chamber where it was superfused at 35 °C. A recording from an experiment with this tissue is shown in Fig. 2. The *p*H-sensitive microelectrode recorded the membrane potential of a Purkinje fibre cell, minus an offset voltage proportional to *p*H$_i$, while a neighbouring cell was impaled with the KCl microelectrode. The KCl microelectrode output voltage was subtracted electronically from that of the *p*H electrode so that when both electrodes were intracellular, a *p*H$_i$ recording could

Fig. 1 Diagrammatic illustration of the preparation pinned into the experimental chamber. It was superfused continuously, and impaled with a conventional, KCl-filled microelectrode (left), and the *p*H-sensitive microelectrode (right). A diagram (not to scale) of ~ 0 2 mm of the tip of the latter is shown at the top.



be obtained (Fig. 2, lower trace) which was independent of any changes in membrane potential. (Ideally both electrodes should be in the same cell. This is theoretically possible, but in practice it was found difficult to obtain good penetrations with both electrodes when the interelectrode distance was < 100 µm.) In this experiment, the preparation was perfused initially with saline equilibrated with 5% CO_2, 95% O_2. External CO_2 was then removed by changing the perfusion solution to one equilibrated with 100% O_2. This produced a transient increase in pH_i followed by a partial recovery to a level higher than in the absence of CO_2. On return to 5% CO_2 there was a transient pH_i decrease followed by a return to the control level. Essentially similar recoveries from changes in pH_i when CO_2 was changed have been observed in crab muscle[4], squid axon[5] and snail neurones[6].

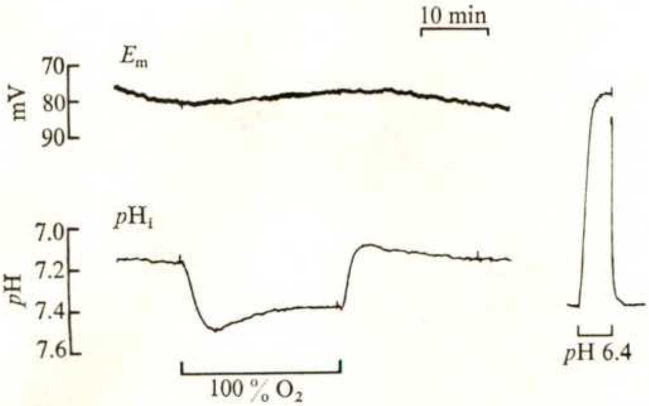


Fig. 2 Pen recording of an experiment to measure pH_i and the response to removal and replacement of external CO_2. The membrane potential was recorded by a conventional microelectrode (top trace) and the pH_i obtained when the pH-sensitive electrode is also intracellular (bottom trace). The pH-sensitivity of the electrode was tested (right) by a reduction of the solution pH to 6.40 (both electrodes extracellular). The preparations were perfused with a bicarbonate-buffered modified Tyrode solution composed of 140 mM Na^+, 4 mM K^+, 2mM Ca^{2+}, 1 mM Mg^{2+}, 2 mM pyruvate, 10 mM glucose, chloride and bicarbonate (reciprocally varied) to give a pH of 7.40 at 35 °C. The bicarbonate required was determined experimentally by titration. CO_2 levels were determined by a CO_2 gas analyser. These varied in nominally 95 % O_2: 5 % CO_2 gas cylinders from 4.25 to 4.79 % CO_2 (mean 4.61). Thus the bicarbonate concentration ranged from 17.5 to 22 mM. In the absence of CO_2 and bicarbonate, solutions contained 10 mM HEPES (*N*-2-hydroxyethyl piperazine-*N*-2-ethanesulphonic acid) buffer (also at pH 7.40). The changes in the pH_i when CO_2 was removed were not altered when Tris-maleate buffer was substituted for HEPES.

The results from a total of 14 experiments are summarised in Table 1. The mean pH_i in the absence of CO_2 is close to 7.2 and is significantly higher than when CO_2 is present. In general, our values for pH_i are somewhat higher than those obtained previously using the DMO technique in dog heart: 6.77 (ref. 7), 6.86 (ref. 8), and 7.01 (ref. 9) although Benson *et al.*[10] have reported similar values to those we have found. Lavellée[2] used open-tipped pH-selective microelectrodes and found a pH_i of 6.9 in rat atrial fibres (stimulated at a rate of 200 min^{-1}).

Table 1 Intracellular pH and membrane potential

Equilibration gas	pH_i	E_m (mV)
100 % O_2	7.20 ± 0.05	71.8 ± 3.7
95 % O_2: 5 % CO_2	7.02 ± 0.04	78.1 ± 2.5

Results are means ± s.e.m.; n = 14. Those from preparations with a membrane potential in 5 % CO_2 of < 60 mV were rejected.

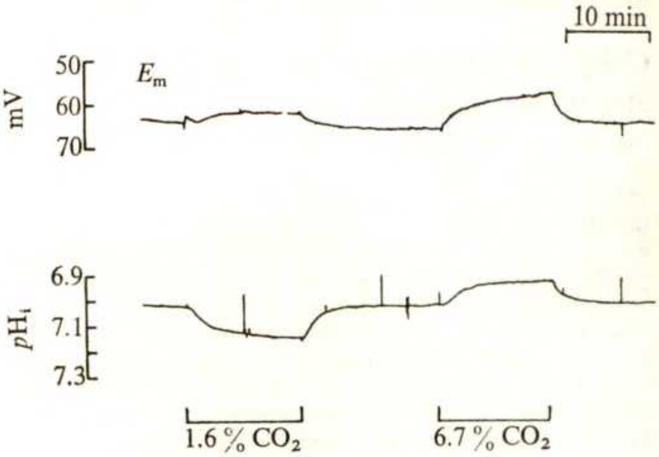

Fig. 3 Change in membrane potential (top) and pH_i (bottom) when the external CO_2 level was changed from 4.7 % to the levels indicated. The bicarbonate concentration (20.5 mM) was maintained constant so that the external pH varied from 7.40 in the control solution to 7.70 and 7.19 respectively in the two test solutions. The potassium concentration in this experiment was 8 mM.

From experiments of the type illustrated in Fig. 1 it is clear that pH_i is greatly influenced by CO_2 in the equilibration gas. We have used different CO_2:O_2 mixtures to see how pH_i varies with alteration of the external pH, and the results of an experiment of this type are illustrated in Fig. 3. All solutions contained the same bicarbonate concentration and were equilibrated with the CO_2 levels indicated. (The pH of these mixtures being measured for each experiment.) Alteration of the CO_2 content produced a change in pH_i to a new steady level within ~ 10 min, presumably by the reaction

$$CO_2 + H_2O = H_2CO_3 = H^+ + HCO_3^-$$

A linear relationship was found between pH_i and the external pH, but the pH_i change was only ~ 40 per cent of the change in external pH. This difference is caused by intracellular buffering.

These responses differ from those observed when the bicarbonate concentration is altered as well as the CO_2 content to maintain a constant external pH. In this case, the responses are similar to those shown in Fig. 1, that is, a large transient initial pH_i change followed by a partial recovery to a level nearer that of the control.

Direct measurement of pH_i with recessed-tip pH sensitive microelectrodes thus enables continuous recording of previously undetectable transient changes. The results show that alteration of CO_2 levels produces rapid changes in pH_i. The partial recovery of these changes when external pH is unchanged suggests the presence of some sort of H^+ pump in the cell membrane.

Origin of plasma α_2HS-glycoprotein and its accumulation in bone

WE have shown previously that a glycoprotein constituent of calcified cortical bone matrix is immunochemically identical to a component of blood plasma[1,2]. In bone and dentine this specific α-glycoprotein is concentrated in amounts relative to plasma albumin but is not present at greater concentrations than in plasma in various other tissues. This material, although mainly present in extravascular sites in bone, could originate from the plasma because it represents a substantial proportion of the radioactivity in bone tissue 12 d after injection of ^{14}C-total plasma glycoprotein[1]. Rabbit bone α-glycoprotein is analogous to human α_2HS-glycoprotein[3,4], which is located in mineralising areas in normal human bone matrix[5]. To our knowledge direct conclusive proof of the tissue origin of the plasma α_2HS-glycoprotein is lacking although most of the serum glycoproteins seem to be synthesised by the liver[6,7]. Nevertheless, its increased concentration in calcified tissues suggests that its presence in plasma could be a result of synthesis and release by bone tissue. We now report that the α_2HS-glycoprotein is synthesised by the liver and a proportion is subsequently accumulated in bone tissue.

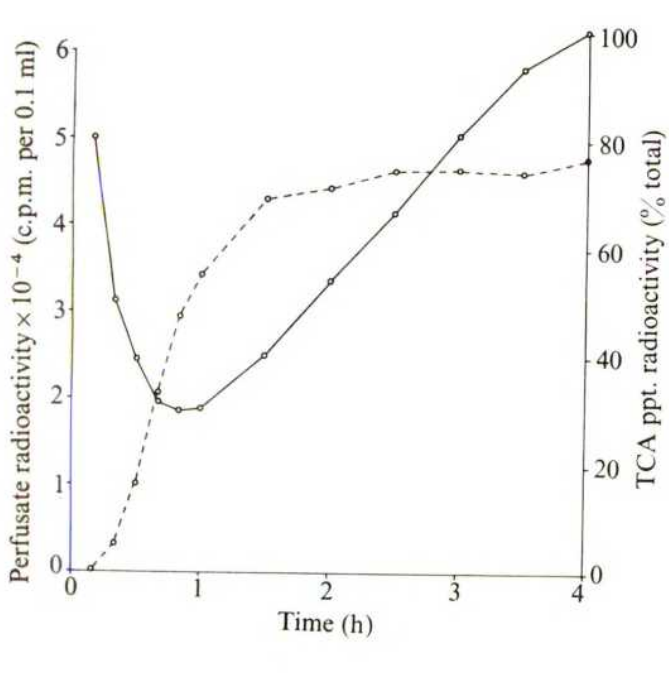

Fig. 1 Total radioactivity in liver perfusion medium (solid line), and the proportion precipitable by TCA (dashed line), with time after introduction of ^{14}C-glucosamine into the perfusate. The perfusion medium consisted of 2.6 g % (w/v) bovine plasma albumin in bicarbonate buffer[9] with bicarbonate added to 25 mM concentration and the addition of human erythrocytes to give 2.5% (w/v) haemoglobin. Blood contained in the liver was washed out with 30 ml perfusion medium before addition of 20 μCi D-1-^{14}C-glucosamine (The Radiochemical Centre, Amersham) to the perfusate. Perfusion was with a total of 50 ml of this medium at a flow rate of 27 ml min^{-1}. Samples (0.5–1 ml) of perfusate were taken at various time intervals up to 4 h after the addition of D-1-^{14}C-glucosamine and centrifuged at 2,000*g* for 30 min at 4 °C to remove erythrocytes. Portions (10 μl) of the supernatants were dissolved in 0.5 ml soluene (Packard) and 5 ml scintillation fluid[10] was added for assay of radioactivity by liquid scintillation. Samples (0.1 ml) of the supernatants were added to 1 ml 12% (w/v) aqueous TCA and allowed to stand overnight at 4 °C. The TCA precipitates were collected by centrifugation at 4 °C at 2,000*g* for 15 min and washed three times with 1 ml 12% (w/v) aqueous TCA containing 1 mg glucosamine ml^{-1}. The washed precipitates and individual supernatants were dissolved in soluene (1 ml) and their radioactive contents determined. All radioactivity determinations were corrected for quenching by internal standardisation.

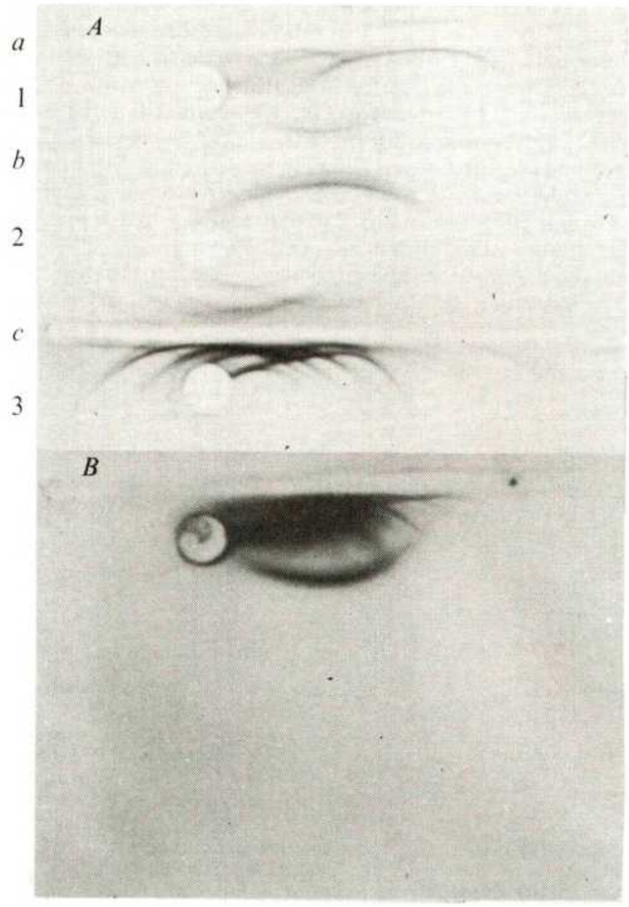

Fig. 2 Immunoelectrophoresis in 1% (w/v) agar gel in sodium barbitone buffer, *p*H 8.6, of rabbit liver perfusion medium and rabbit plasma against antiserum to rabbit plasma and antiserum to rabbit bone α-glycoprotein (*A*) and its autoradiograph (*B*). Electrophoresis was for 2 h at 100 V and autoradiography was by exposure to Kodirex X-ray plates (Kodak) for 10 d. Well (1), Perfusion medium 4 h after adding D-1-^{14}C-glucosamine. Well (2), Rabbit plasma to which an amount of D-1-^{14}C-glucosamine was added which was equivalent to the radioactivity present in well (1). Well (3), Rabbit plasma, non-radioactive. Troughs (*a*) and (*c*), Anti-rabbit plasma antiserum. Trough (*b*), Anti-rabbit bone α-glycoprotein antiserum.

Livers of 300–350 g Dutch rabbits were perfused *in situ* with medium containing D-1-^{14}C-glucosamine by a modification of the method of Hems *et al.*[8]. Total perfusion medium radioactivity fell rapidly to about the 1 h time point as the perfused liver removed radioactive precursor. This value then increased for the rest of the perfusion period (Fig. 1). With time of perfusion the radioactivity which was precipitable by trichloroacetic acid (TCA) increased from 5% at 20 min to 77% at 4 h. Column chromatography on BioGel P30 confirmed that TCA precipitability represented macromolecular radioactivity as similar results were obtained by both methods. Macromolecular radioactivity first appeared in the medium 10–20 min after addition of labelled precursor and this indicates the time required for uptake, synthesis and secretion of the glycoproteins by the liver[11]. 7% (w/v) polyacrylamide disk gel electrophoresis of the perfusion medium showed that a large proportion of the radioactively-labelled material had α-electrophoretic mobility (not shown).

Agar gel immunoelectrophoresis followed by autoradiography (Fig. 2) indicated that the liver perfusate contained numerous proteins reactive against polyvalent anti-rabbit plasma antiserum and their synthesis during perfusion is demonstrated by the autoradiogram. Antiserum against purified rabbit bone α-glycoprotein was produced as described previously[1] and Fig. 2 shows that liver synthesised a component showing immunological identity with this glycoprotein. No interaction between the immunoprecipitates and D-1-^{14}C-glucosamine during the washing and staining procedure was observed (Fig. 2). These results show that the liver is capable of synthesising the α-glycoprotein which has been found to make up approximately 4% of the rabbit cortical bone non-collagenous organic matrix[1].

To test whether bone tissue could also synthesise this component, eight rabbit half-calvaria (25 d gestation) were cultured, each in 1.5 ml medium for 48 h in the presence of 7.5 μCi 1-^{14}C-glucosamine, by the method of Reynolds[12]. After culture the embryonic bones were individually pooled and the non-collagenous proteins prepared by the method of Herring *et al.*[13].

The culture medium at 48 h contained very little radioactivity in macromolecular components (0.6% of total medium radioactivity) as assessed by chromatography on BioGel P30. DEAE-cellulose chromatography of macromolecular radioactivity from cultured bone collagenase digests showed that only 17% of the total radioactivity applied was eluted in the position of the particular α-glycoprotein under investigation[1,2]. This contrasts with the situation *in vivo* after D-1-^{14}C-glucosamine injection where a greater proportion is eluted in this less acidic fraction[1]. Immunoelectrophoresis of the less acidic fractions of cultured bone collagenase digests, which contained appreciable amounts of radioactivity, showed detectable amounts of α-glycoprotein (Fig. 3). But neither this immunoprecipitate nor any serum protein precipitated by polyvalent anti-rabbit plasma antiserum (Fig. 3) contained radioactivity as assessed by autoradiography on Kodirex X-ray plates for up to 60 d. Therefore embryonic bone tissue cannot synthesise this particular α-glycoprotein, even though it is present in foetal plasma (our unpublished observations).

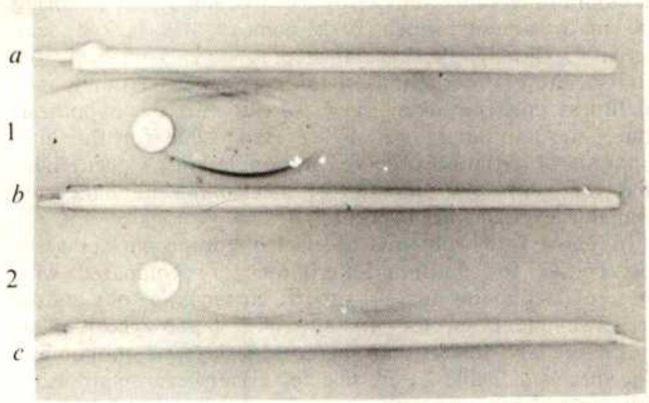

Fig. 3 Bone non-collagenous proteins prepared by the method of Herring *et al.*[13] were chromatographed on DEAE-cellulose as described previously[1,2]. The peak of radioactivity corresponding to the 0–0.2 M NaCl eluate was pooled, dialysed exhaustively against distilled water and freeze dried. The freeze-dried material was dissolved in 0.05 M Tris-HCl buffer *p*H 7.2 (0.2 ml) and samples (10 μl) of the solution used for immunoelectrophoresis in agar gel (1% w/v in sodium barbitone buffer *p*H 8.6). Stained with 1% amido black in 7% acetic acid. Well (1), 0–0.2 M NaCl eluate+normal rabbit plasma. Well (2), 0–0.2 M NaCl eluate. Troughs (*a*) and (*c*), Anti-rabbit plasma antiserum (40 μl). Trough (*b*), Anti-rabbit bone α-glycoprotein antiserum (40 μl).

The present results confirm our previous suggestion[1] that the rabbit α-glycoprotein analogous to human α_2HS-glycoprotein, which is concentrated in bone tissue relative to plasma albumin, is synthesised by the liver. These results are also the first direct demonstration that the α_2HS-glycoprotein is made by the liver, as implied by the work of Miller[6,7].

The accumulation of this α-glycoprotein in calcified matrix could be a result of its affinity for adsorption sites on bone mineral and our current work[3] confirms that this concentration effect occurs during the precipitation of calcium phosphates *in vitro*. This suggests a relatively high affinity of this plasma protein for calcium and the concentration in bone matrix could represent an aspect of a more basic involvement in calcium metabolism.

Certain serum fractions have been shown to delay the rate of transformation *in vitro* of an amorphous calcium phosphate to a more crystalline hydroxyapatite[14]. Whether the binding of the α-glycoprotein has any specific influence upon the rate of formation or on the nature of the bone mineral phase *in vivo* is not known. Whatever the physiological function of the particular affinity of the α_2HS-glycoprotein for bone matrix, our demonstration that this material is synthesised by the liver but not by bone tissue has interesting implications for bone physiology.

We thank Professor Sir Hans Krebs for helpful advice and Mr Philip Gregory of Professor Krebs' laboratory, Oxford for technical help with the liver perfusions. J.T.T. and M.E.O. are members of MRC External Scientific Staff.

*Data refer to caucasians only. No variants were detected at other enzyme loci listed in Harris *et al.*[7] and in Harris and Hopkinson[8], or there is no direct information as to whether they are monomers or multimers. In loci with very low heterozygosities observed differences in H may be of no significance. Loci with an H less than 0.01 may be characterised as monomorphic. Using this criterion 22 out of 33 multimers and 6 out of 17 monomers are monomorphic ($\chi^2 = 4.48$, d.f. = 1, $P = 0.034$). †DH, dehydrogenase.

which the fitness of the heterozygote exceeds the fitness of both homozygotes—is responsible for the maintenance of genetic variability in populations[1]. It has been proposed[2–4] that heteromultimers formed by random association of enzyme subunits coded by two different alleles provide a molecular basis for overdominance. This hypothesis stems from the observation that heteromultimers often differ from homomultimers in a number of aspects[5], sometimes restoring enzymatic activity when both homozygotes lacked such activity[2]. Clearly, the crucial step towards associating (or disassociating) observations of this type with overdominance of fitness must be taken if we were to test the hypothesis that heteromultimers *per se* are responsible for the high amounts of variation observed in populations. I argue here that the enormous amounts of electrophoretic data now available exclude this hypothesis.

In Table 1 the amounts of electrophoretic variability of loci coding for multimeric enzymes are compared with those of loci coding for monomeric enzymes in four animal and two plant species. In all cases heterozygosities at multimers are lower than heterozygosities at monomers. The species in Table 1 were selected either because a reasonably large number of both types of enzyme loci were studied and because the number of assayed individuals is quite high to allow one to ignore errors in gene frequency estimates, or because they represent broad taxonomic units embracing, practically, all diploid organisms. Data from other species of mammals, lizards, fish, fruit flies, and snails could be cited, the great majority of which seem to support this conclusion (for data on human enzyme loci see Table 2).

It has been argued that enzymes with multiple substrates[26] and enzymes regulating the flux through a pathway[27] are more variable than enzymes with single substrates or non-regulatory enzymes. The class of non-regulatory enzymes contains more multimers than monomers so it can be argued that the difference in amounts of variation is ultimately related to function rather than to presence or absence of hybrid bands. The validity of these hypotheses is in doubt as there is a growing list of enzymes with multiple substrate and with regulatory properties which, nevertheless, are exceptionally conservative[28]. But the argument that the difference in amount of polymorphism indicated here is ultimately related to function rather than to degree of polymerisation can be dealt with in a more direct way. In Table 3 I have listed amounts of electrophoretic variability of monomeric and multimeric enzymes of same *in vitro* biochemical function. Out of 27 pair-wise comparisons that

are possible from Table 3, monomers have a higher amount of heterozygosity in 20. Evidently, within a given species or population monomeric enzymes are more polymorphic than multimeric enzymes of similar function.

After the demonstration[35-36] that populations do indeed contain alleles of same electrophoretic mobility one is not allowed to directly translate electrophoretic variability to actual variability. If polymerisation interferes with the electrophoretic expression of charge changes, then it is possible that amino acid substitutions result in changes in electrophoretic mobility more often in monomers than in multimers. There is evidence, however, that the number of different electrophoretic states that multimeric enzymes can assume is as high as, if not higher than, in monomeric enzymes. Some enzymes with the highest observed numbers of electrophoretic alleles are multimers: esterase B of *Dacus oleae*[32] (12 electrophoretic alleles), esterase 5 of *Drosophila pseudoobscura*[37] (12); acetaldehyde oxidase and xanthine dehydrogenase of *Drosophila willistoni*[23] (11 and 10, respectively); esterase E of *Colias eurytheme*[38] (13); esterase d of *Hemiagrus isola*[39] (18). In humans the enzyme with the highest observed number of electrophoretic alleles, 18 in all, is the dimeric placental alkaline phosphatase[40].

Lewontin (ref. 1, p. 71) has stressed the point that small amounts of unconditional overdominance will quickly lead to high degrees of heterozygosity. If heterozygotes for multimeric enzymes are endowed with high fitness and heterozygotes for monomeric enzymes are not, then we would expect multimeric enzymes to possess higher amounts of variation than monomeric enzymes. The opposite is true. Unless one assumes that the variation in multimers is maintained by overdominance, whereas the much higher variation in monomers is neutral or is maintained by some other form of balancing selection, it becomes difficult to adhere to the hypothesis that heteromolecules provide a basis for overdominance of fitness.

The evidence presented here renders the hypothesis of widespread unconditional overdominance less attractive, but it does not exclude the possibility that other forms of heterozygote superiority, such as marginal overdominance[41], are of importance in evolution Gillespie and Langley[26] have shown, however, that if selection coefficients fluctuate greatly as a result of change in the environment, then heterozygote intermediacy can often result in stable polymorphism. Their review of the literature shows that very rarely, if ever, do heterozygotes assume values above or below the range specified by the two homozygotes. Heterozygote intermediacy is also a concomitant of frequency dependent selection[42]. It seems very possible that, whatever fraction of the genetic variation is selectively maintained, the type of selection involved is one of fluctuations in selection coefficients with no intrinsic heterozygote superiority.

I thank Drs M. L. Tracey and G. R. Babbel for providing me with unpublished information. This work was supported by a grant from the NRC of Canada.

Genetic transformation in *Drosophila* by microinjection of DNA

THE experiments described here provide new evidence for DNA-induced gene-specific alterations in *Drosophila.* Host embryos homozygous for recessive alleles of several genes were treated with wild-type DNA by embryo microinjection. Several of the adults which developed from these injected embryos exhibited phenotypic alterations whereas none of the controls treated with host-type DNA showed any altered phenotype. In addition, the alterations were in two cases transmitted to the progeny of the injected flies, so that altered stocks could be established. If this represents genetic transformation and if it can be made to work routinely in eukaryotes, it promises to be equally or more useful than the corresponding process in prokaryotes, since it could be used to bioassay specific parts of the genome which are currently being isolated by various techniques.

Ten years ago Fox and Yoon[1] reported that *Drosophila* embryos soaked in solutions of DNA showed somatic changes in the emerging adults, and subsequently germinal changes[2], that were specific to the DNA used. In addition to *Drosophila*, the uptake, expression and transmission of exogenous DNA has been reported in both *Neurospora* and mammalian cells *in vitro*, as well as in a number of organisms less suited to further genetic analysis[3-7]. The fungal transformation phenomenon was observed after addition of wild-type DNA (or poly(A)-rich RNA) to the growth medium of a fragmented mutant culture[8-10]. The change observed in most studies was an alteration of the organism's dependence on inositol in the culture medium. The frequency of transformation was significantly greater than the observed reversion frequency, either spontaneous or induced, for the mutation. The treatment of cultured mammalian cells with metaphase chromosomes from different species and the subsequent detection of donor enzyme activity in clones derived from the treated cells[11-13] demonstrates further that higher eukaryotes can incorporate and utilise exogenous genetic material.

In *Drosophila*, somatic as well as germ-line alterations have been observed after soaking embryos in solutions of DNA extracted from genetically different animals. The process used to obtain eggs permeable to DNA is not, however, completely satisfactory. It involves inducing animals to lay premature eggs and has been found difficult as well as largely ineffective (less than 2% of the eggs were shown by autoradiography to take up the DNA)[14]. In an effort to streamline the transformation experiments (by eliminating the scoring of untreated animals) and to enable some quantification of the treatment, we have adapted an egg microinjection method[15] for this procedure. Although this process limits the number of embryos which can be treated, because of the low survival rate, it allows precision in the delivery of exogenous DNA and serves to increase the chance that a treated egg will be altered genetically.

The genetic outline of our experiment was basically the same as that used by Fox and Yoon[2]. Eggs collected from flies homozygous for the mutations *vermilion*, *v*, and *brown*, *bw*, were used as hosts for DNA extracted from wild-type adults. *Vermilion* and *brown* represent mutations in the ommochrome and pteridine biosynthetic pathways, respectively, and in combination result in the absence of pigment from the adult eyes. Furthermore, *vermilion* is non-autonomous in its expression so that a small patch of non-mutant tissue in the body of the animal can allow the eyes to develop the wild-type phenotype (brown pigmentation) in an otherwise mutant animal. This system, previously exploited by Fox, allows a "magnification" in the detection of first generation alterations, since transformation of tissues other than the eye can be detected by its effect on eye pigmentation. In addition, all hosts were homozygous for *yellow* (a cuticle marker) and most were homozygous for *forked* (a bristle mutation) and *maroon-like* (a mutation which can be detected by lack of staining for aldehyde oxidase in the internal organs). Embryos were injected during the nuclear multiplication stage. During this stage of embryogenesis the nuclei are dividing rapidly (13 divisions at 10-min intervals at 25 °C) and the embryo is a syncytium, that is, no cell membranes separate the nuclei. Injection at this stage should maximise the potential interaction between nuclei and exogenous DNA.

Table 1 Eye pigmentation in adults developing from embryos injected with DNA

Treatment	Adults emerged	Adults with pigmented eyes	Fertile adults*	Adults with pigmented progeny
v^+ DNA	138	8	100	2
v DNA	87	0†	61	0

DNA was extracted from whole adults by a procedure similar to that of Tartof[17]. A nuclear preparation was deproteinised using a mixture of chloroform–isoamyl alcohol (24:1) and phenol. The DNA was precipitated, resuspended and treated successively with RNase, Pronase, and phenol. The resulting preparation was dialysed extensively against SSC (0.15 M NaCl, 0.015 M sodium citrate) and then a modified insect Ringer's solution[18]. The DNA was then frozen in 100-µl aliquots at −70 °C. The concentration of DNA injected varied and the results above represent the animals surviving treatment with 44–100 µg ml^{-1}. Preblastoderm embryos 30–60 min old were injected with 10^{-4} µl DNA through glass needles 10–13 µm inner diameter. The injected embryos were maintained until hatching at 18–20 °C and the larvae were subsequently raised in yeast paste at 25 °C. The emerging adults were coded, scored, and then allowed to breed for at least 10 d with animals of the host stock. All F_1 progeny were scored for eye colour and 10 pairs of F_1 from each adult were maintained. F_2 and F_3 were similarly scored for deviations from expected eye colour.

*Adults whose progeny were scored at least three generations.

†$0.01 < P < 0.025$.

The results of these injections with respect to alterations of *vermilion* expression are summarised in Table 1. A significant number of adults developing from treated embryos had pigmented eyes. One of these flies also transmitted the pigmentation to one of his progeny forming a stable transformed line. Another stable line was established from the recovery of pigmented F_2 from an unpigmented injected animal. Genetic analysis of the two transformed lines demonstrated that the alterations were both linked to the X chromosome, which carries the *vermilion* locus. The alteration in one line is dominant and maps near *v* (1–33.2), whereas the other is semi-dominant and maps to the distal end of the chromosome (1–0.01). These results are similar to those of Fox *et al.*[16] and to the preliminary observations made by Limbourg-Bouchon using microinjection (B. Limbourg-Bouchon, personal communication). Neither of these lines showed any instability in the expression of the pigmentation after the first pigmented flies were isolated, nor has there been any reversion in the stocks. This contrasts with the behaviour of stocks produced by other workers where phenotypic instability (interpreted as somatic mosaicism of expression) and reversion are quite common[2,16], suggesting that there may be qualitatively different events induced by the DNA treatment. Adults were also examined for alterations in the expression of *y*, *bw*, *f*, and *mal*, but no alteration was observed (*y* and *bw*, 138 cases; *f* and *mal*, 88 cases). The detection of altered expression in these autonomous genes may be significantly less likely than for non-autonomous genes such as *vermilion*. It is also likely, however, that the transformation rate will be characteristic for each gene and that these other genes might simply transform at a lower frequency.

Our results indicate that the phenomenon observed by Fox and Yoon[2] can be duplicated using egg microinjection. In addition, the frequency of altered expression is significantly greater than that observed by soaking eggs (5% first generation transformants as opposed to 0.8%)[2]. Preliminary results from other laboratories using this technique indicate that an even higher rate may be attainable (B. Limbourg-Bouchon, personal communication; C.P. Liu, and A. S. Fox, personal communication). Microinjection allows precision in delivery, circumvents the uptake phenomenon which may be selective, and allows precise staging of each embryo. Experiments are now under way to transform loci whose genetic fine structure will allow an analysis of the mechanisms underlying this apparent genetic transformation.

I thank Drs Peter Bryant and Howard Schneiderman for their encouragement and support, and Mark Blake and Pat Venta for their technical assistance. This work was supported by a grant and a Predoctoral Traineeship from the NIH.

Integrator gene in *Aspergillus nidulans*

ONE of the most intriguing problems in genetics is how the regulation of a particular structural gene can be programmed in such a way that its expression can be elicited in a variety of different contexts. Stated differently, how can the concomitant expression of two or more non-contiguous structural genes capable of independent expression be achieved? Britten and Davidson[1-3] have proposed a model for gene regulation which gives considerable insight into this problem. One feature of their model is the existence of positively acting regulatory genes, designated integrator genes, whose role is to achieve precisely this concomitant expression of non-contiguous structural genes. Although the model was developed to account for cell differentiation in higher eukaryotes, a similar, although possibly less elaborate, form of regulatory machinery might be applicable in lower eukaryotes. In the fungus *Aspergillus nidulans*, as in higher eukaryotes, functionally related genes are seldom clustered[4]. Given the considerable metabolic versatility of this organism, instances of inducible enzymes participating in more than one metabolic pathway should not be unduly rare. Evidence for the existence of integrator genes could come from the study of regulatory mutations affecting such enzymes. The model also requires the existence of receptor sites for integrator gene products, a not implausible requirement for *A. nidulans*, where several *cis*-acting regulatory mutations tightly linked to structural genes under their control have been identified (refs 5–8 and unpublished results of C. R. Bailey and H. N. A.). Here I report that the *int*A gene of *A. nidulans*, previously designated *amd*R and shown by Hynes and coworkers[9-11] to be a positive regulatory gene in linkage group II involved in acetamidase synthesis, is an integrator gene of the type described by Britten and Davidson. Moreover, *int*A is possibly especially interesting because one of the compounds whose metabolism it controls is γ-amino-*n*-butyric acid (GABA), whose metabolism has been extensively investigated in a wide variety of organisms because of its role in the regulation of neuronal activity.

Three probable structural genes are under *int*A control: *amd*S, the structural gene for acetamidase in linkage group III[9-11]; *gat*A in linkage group VII where recessive mutations eliminate GABA transaminase which also participates in the catabolism of β-alanine, δ-amino-*n*-valerate, and several other ω-amino acids (H. A. Penfold and H. N. A., unpublished); and *gab*A in linkage group VI where recessive mutations result in loss of a GABA-specific permease (H. A. Penfold and H. N. A., unpublished). *amd*A, another regulatory gene probably specifically controlling *amd*S, is located 5.3 ± 1.8 cM from *gat*A. But there is no interaction in double mutants and no reason to suppose that this linkage has any special significance.

*int*A mutations can affect expression of one or more of the structural genes. Partially dominant *int*A^c mutations can lead to high, constitutive levels of acetamidase[9,11] whereas recessive *int*A$^-$ mutations halve acetamidase levels[9]. *int*A mutations do not affect the structure of acetamidase[10]. *In vivo* effects of *int*A mutations are given in Tables 1 and 2. *int*A^c–2, –300, –302, and –304 enhance to varying extents utilisation of acrylamide and acetamide as nitrogen sources and acetamide as carbon source (Table 1). This enhancement is closely correlated with their abilities to suppress *are*A^r mutations for utilisation of acetamide as nitrogen source (Table 2). *are*A^r mutants lack a positively acting regulatory substance necessary for the synthesis of ammonium-repressible enzymes and consequently are unable to utilise nitrogen sources other than ammonium in glucose-minimal medium[7,12]. *int*A$^-$ mutations somewhat reduce utilisation of acetamide. *amd*A^d mutations enhance acetamide but not acrylamide utilisation and suppress *are*A^r mutations on acetamide. Expression of the *int*A^c and *amd*A^d phenotypes on acrylamide and acetamide media requires a functional allele of the *amd*S but not *gab*A and *gat*A genes. The strict additivity of *int*A$^-$–101 and the partially dominant *amd*A^d–301 in strains carrying both mutations (Tables 1 and 2) suggests that, as predicted by Britten and Davidson[2], *int*A and *amd*A might be regulating *amd*S in a parallel, positive fashion. As *int*A$^-$ mutations do not abolish amide inducibility of acetamidase[9], this form of regulation might involve *amd*A. Selection of *amd*A$^-$ alleles and a biochemical study of the effects of *amd*A mutations on acetamidase regulation are intended.

Effects of *int*A mutations on expression of the *gat*A gene are seen in Tables 1 and 3. *int*A$^-$ mutations prevent utilisation of GABA, β-alanine, and δ-amino-*n*-valerate as nitrogen sources and GABA as carbon source (Table 1). *int*A^c–2, –300, –302, –304, and –305 slightly enhance δ-amino-*n*-valerate utilisation. Mutants defective in the *orn*B gene in linkage group VIII are blocked before L-ornithine in the biosynthesis of L-arginine and require either ornithine or arginine[4,13]. GABA and β-alanine but not δ-amino-*n*-valerate can supplement *orn*B$^-$ strains (Table 3) but not the arginine/ornithine auxotrophies[4,13] of *orn*A–4, *orn*C–31, and *orn*D–10 strains or the arginine auxotrophies[4,13] of *arg*A–1, *arg*B–2, and *arg*C–3 strains. GABA and β-alanine, however, cannot supplement *orn*B$^-$ strains also carrying an *int*A$^-$ or *gat*A$^-$ mutation. *int*A^c–2, –300, –302, –304, and –305 exert, to varying degrees, locus-specific suppression of *orn*B$^-$ auxotrophies (Table 3) although not suppressing *orn*A–4, *orn*C–31, *orn*D–10, *arg*A–1, *arg*B–2, and *arg*C–3. This physiological suppression requires that the *gat*A gene but not the *amd*S and *gab*A genes be functional: *int*A^c *gat*A$^-$ *orn*B$^-$ triple mutants require arginine or ornithine and do not respond to GABA or β-alanine. *orn*B$^-$ mutations probably abolish the transaminase which normally converts *N*-acetyl-L-glutamic γ-semialdehyde to N^{α}-acetyl-L-ornithine. When induced by GABA or β-alanine or rendered constitutive by an *int*A^c mutation, the GABA transaminase can apparently catalyse this conversion.

Expression of the *gab*A permease in *int*A mutants can be followed in Tables 1 and 2. GABA is extremely toxic to *gat*A$^-$ mutants. *gab*A$^-$ and *int*A$^-$ mutations relieve this toxicity by reducing GABA uptake (H. A. Penfold and H. N. A., unpublished) so that *gab*A$^-$ *gat*A$^-$ and *int*A$^-$ *gat*A$^-$ double mutants but not *gat*A$^-$ single mutants can grow on GABA plus another nitrogen source such as nitrate (Table 1). Given their lack of *gat*A expression, the very growth of *int*A$^-$ mutants on GABA plus nitrate also illustrates lack of *gab*A expression. The

—, No growth; ±, very slight growth; + up to 5+, increasing levels of growth. Growth scores on different media are not necessarily equivalent, but 5+ represents the maximum growth observed on any medium.

Growth tests were carried out at 37 °C on appropriately supplemented minimal medium[15] as described previously[16]. At least several different strains of each relevant genotype were tested. Nitrogen sources were added to 1% D-glucose-containing media at 10 mM (acrylamide, acetamide, sodium nitrate) or 5 mM (β-alanine, GABA, δ-amino-*n*-valerate). Carbon sources were added to a final concentration of 50 mM to glucose-free media. Growth scores on different media are not necessarily equivalent. All strains listed above utilise L-glutamate and L-aspartate normally as nitrogen or carbon sources.

*int*A^{c}–2 (formerly *amd*R^{c}–2), *int*A^{-}–44 (formerly *amd*R^{-}–44), and *amd*S–17 were provided by Dr M. J. Hynes, who has described their selection[9]. *int*A^{c}–300, *amd*A^{d}–301, and *int*A^{c}–302 (formerly designated *amd*^{d}–300, –301, and –302) were obtained as suppressors of *are*A^{r}–1 on acetamide as described previously[12]. *int*A^{c}–304, *amd*A^{d}–303, and *int*A^{c}–305 were obtained after *N*–methyl–*N′*–nitro–*N*–nitrosoguanidine (NTG) mutagenesis[17] of a strain of genotype *bi*A–1 *are*A^{r}–2 *fw*A–1 (biotin-requiring, unable to utilise nitrogen sources other than ammonium, fawn conidial colour) as suppressing *are*A^{r}–2 on acetamide, acetamide, and GABA as nitrogen sources, respectively. *int*A^{-}–100 and –101 were obtained as spontaneous mutations in strains of genotype *paba*A–1 *int*A^{c}–2 *mau*A–2 (*p*-aminobenzoate-requiring, *int*A^{c}–2 phenotype as described herein, lacking monoamine oxidase) and *pu*A–2 *int*A^{c}–300 (putrescine-requiring, *int*A^{c}–300 phenotype as described herein), respectively, resulting in resistance to 4 mg ml^{-1} 2-fluoroacetamide (Fluka, Buchs, Switzerland) on medium containing 72 mM acetate (*p*H 6.5) as sole carbon source and 5 mM urea as sole nitrogen source. *gab*A–2 and –6 were selected as unable to utilise 5 mM GABA as nitrogen source after NTG mutagenesis of a strain of genotype *bi*A–1 *pu*A–2 *fw*–A–1 using the putrescine starvation selection technique[18]. *int*A^{-}–105, –106, –107, and –500 and *gat*A–1 were selected after ultraviolet mutagenesis of a strain of genotype *paba*A–1, using replica plating[19], as able to utilise 5 mM L-proline but not 5 mM β-alanine as nitrogen source. *gat*A–2 was selected by Mr K. N. Rand. It was obtained after ultraviolet mutagenesis of a strain of genotype *paba*A–1 *are*A^{r}–120 as allowing utilisation of 10 mM acrylamide as nitrogen source in the presence of 1% (v/v) glycerol as sole carbon source. This weak suppression is presumably associated with the slight enhancement of acetamide and acrylamide utilisation by *gat*A^{-} mutations (which will nevertheless not suppress the more stringent *are*A^{r} alleles on acetamide or acrylamide) as seen above. A likely explanation is that *gat*A^{-} mutations enhance the accumulation of an endogenous inducer such as β-alanine which can activate the *int*A product, as no such enhancement occurs in strains also carrying an *int*A^{-} mutation.

Allelism has been demonstrated both by tight linkage (generally less than 0.5 cM) and, for recessive mutations resulting in loss of function, by a lack of complementation in diploids. The leakiest *int*A^{-} allele, *int*A^{-}–500, does not complement with *int*A^{-}–44, –100, –101, –105, –106, or –107. The *int*A^{-} mutations are recessive to *int*A^{+} on the media listed above whilst *int*A^{c}–2 is partially dominant to both *int*A^{+} and *int*A^{-}–101.

ability of the five *int*A^{c} mutations to suppress *are*A^{r} for utilisation of GABA as nitrogen source (Table 2) probably primarily reflects enhanced levels of the *gab*A permease because suppression of *are*A^{r} on GABA can also be achieved by a *cis*-dominant regulatory mutation tightly linked to *gab*A (unpublished results C. R. Bailey and H. N. A.). Suppression of *are*A^{r} on GABA requires functional alleles of both *gab*A and *gat*A but not *amd*S. The selection of mutations able to suppress *are*A^{r} mutations on two or more nitrogen sources metabolised by different pathways is probably a general method for obtaining derepressed alleles of integrator genes, provided synthesis of the necessary enzymes and permeases does not have an absolute requirement for a functional *are*A product (K. N. Rand and H. N. A., unpublished).

The probable route of GABA catabolism is shown in Fig. 1. Although *int*A controls both GABA uptake and transamination, it apparently does not regulate succinic semialdehyde dehydrogenase because *int*A^{-} strains utilise γ-hydroxy-*n*-butyrate as a carbon source. *ssu*A—1 strains can utilise neither GABA nor γ-hydroxy-*n*-butyrate as carbon sources (C. R. Bailey and H. N. A., unpublished).

As well as controlling three structural genes, the *int*A product must respond to at least two effectors, GABA and β-alanine or their derivatives, as shown by their ability to supplement *orn*B^{-} auxotrophies. If the *int*A product be directly involved in regulating *amd*S, *gat*A, and *gab*A, mutations affecting the specificity of the *int*A product might fall into one or both of two categories: (1) those having a differential effect on the expression of the three structural genes; and (2) those affecting response to one of the effectors more than the other. *int*A^{-}—500 is probably of the latter type since it affects responses to β-alanine much more drastically than responses to GABA or δ-amino-*n*-valerate (Tables 1 and 3). The lack of additivity of *int*A^{-}—500 and *gab*A—2 in double mutants and the relative resistance of *int*A^{-}—500 *gat*A—1 double mutants to GABA supports this conclusion. The fully *int*A^{-} phenotype of *int*A^{-}—500 on acetamide (Table 1) plus its resistance to acetamidase-catalysed, lethal hydrolysis of 2-fluoroacetamide[9] might indicate that *int*A^{-}—500 also falls into the first specificity category, stringently affecting *amd*S. It is more likely, however, that the mutant responses of *int*A^{-} strains to acetamide and its analogues are dependent on a small amount of endogenous effector

Table 2 Suppression of *are*A^{r} mutations

Relevant genotype	Nitrogen source δ-Amino-*n*-valerate or β-alanine or NO_3^-	Acetamide	GABA	NH_4^+
Wild type (*are*A^{+})	5+	5+	5+	5+
*are*A^{r}–1, –2, –19	–	–	–	5+
*int*A^{c}–2 *are*A^{r}–1,–2,–19	–	4+	3+	5+
*int*A^{c}–300 *are*A^{r}–1	–	3+	2+	5+
*int*A^{c}–302 *are*A^{r}–1	–	3+	+	5+
*int*A^{c}–304 *are*A^{r}–2	–	3+	±	5+
*int*A^{c}–305 *are*A^{r}–2	–	–	3+	5+
*amd*A^{d}–301 *are*A^{r}–1, –2, –19	–	3+	–	5+
*amd*A^{d}–303 *are*A^{r}–2	–	3+	–	5+
*int*A^{c}–304 *amd*A^{d}–301 *are*A^{r}–2	–	4+	±	5+
*int*A^{c}–2 *amd*S–17 *are*A^{r}–1	–	–	3+	5+
*int*A^{c}–2 *gab*A–2 *are*A^{r}–2	–	4+	–	5+
*int*A^{c}–2 *gat*A–2 *are*A^{r}–2	–	4+	–	5+
*amd*A^{d}–301 *amd*S–17 *are*A^{r}–1	–	–	–	5+
*amd*A^{d}–301 *int*A^{-}–101 *are*A^{r}–2	–	+	–	5+
*int*A^{-}–101 *are*A^{r}–1, –2	–	–	–	5+
*amd*S–17 *are*A^{r}–1	–	–	–	5+
*gab*A–2 *are*A^{r}–2	–	–	–	5+
*gat*A–2 *are*A^{r}–1, –2	–	–	–	5+

See legend to Table 1 for most details. Ammonium was added at 10 mM as the (+)-tartrate *are*A^{r}–1, –2, and –19 (formerly *amd*T–19) have been described previously[12] and lead to inability to utilise nitrogen sources other than ammonium. Growth scores on different media are not necessarily equivalent. When tested in diploids homozygous for *are*A^{r}–2, *int*A^{c}–2 and *amd*A^{d}–301 are partially dominant. None of the *int*A^{c} or *amd*A^{d} mutations suppress *are*A^{r} mutations on L-glutamate or L-aspartate as nitrogen sources

interacting with the *int*A product in *int*A^{+} strains. The behaviour of *int*A^{-}–500 might therefore suggest that β-alanine, an essential metabolite for synthesis of coenzyme A, is that effector. Its concentration must be sufficiently low for *orn*B^{-} mutations to result in complete auxotrophy. Low levels of β-alanine and GABA have been detected in *Neurospora crassa*[14].

*int*A^{c}–305 and –304 are probably specificity mutations of the first category. *int*A^{c}–305 strongly affects *gab*A expression but has little effect on expression of *amd*S and *gat*A. The opposite is true of *int*A^{c}–304. This indicates that the *gab*A receptor site for the *int*A product differs from those of the *amd*S and *gat*A genes. A diversity of receptor sites for the *are*A product has already been postulated[7]. The existence of such opposite phenotypes among *int*A alleles is only compatible with direct regulatory involvement of the *int*A product. Indirect involvement could only lead to a hierarchy of structural gene

Table 3 Supplementation and suppression of *orn*B^{-} mutations

Relevant genotype	Supplement L-Arginine or L-ornithine	β–Alanine	GABA	None
Wild type (*orn*B^{+})	5+	5+	5+	5+
*orn*B–7, –8, –9, –20, –300	5+	4+	3+	–
*int*A^{c}–2 *orn*B–7, –8, –9, –20, –300	5+	5+	5+	5+
*int*A^{c}–300 *orn*B–7	5+	5+	5+	2+
*int*A^{c}–302 *orn*B–7	5+	5+	5+	4+
*int*A^{c}–304 *orn*B–7	5+	5+	5+	3+
*int*A^{c}–305 *orn*B–7	5+	5+	5+	±
*amd*A^{d}–301 *orn*B–7	5+	4+	3+	–
*int*A^{c}–2 *amd*S–17 *orn*B–7	5+	5+	5+	4+
*int*A^{c}–2 *gab*A–2 *orn*B–7	5+	5+	5+	4+
*int*A^{c}–2 *gat*A–1, –2 *orn*B–7	5+	–	–	–
*amd*S–17 *orn*B–7	5+	4+	3+	–
*gab*A–2 *orn*B–7	5+	4+	3+	–
*gat*A–1, –2 *orn*B–7	5+	–	–	–
*int*A^{-}–101 *orn*B–7	5+	–	–	–
*int*A^{-}–500 *orn*B–7	5+	–	+	–

See legends to Tables 1 and 2 for most details. Supplementation by L-arginine and L-ornithine (as the monohydrochlorides) was tested at 5 mM with or without another nitrogen source. Unsupplemented medium contained 10 mM ammonium as nitrogen source. β-alanine and GABA were added with or without uric acid (100μg ml^{-1}) although they definitely supplement more efficiently in the absence of another nitrogen source. GABA supplementation of *orn*B^{-} strains is considerably improved by using strains also carrying a mutation relieving ammonium repression such as *mea*A–8[16,20] or *are*A^{d}–102 (formerly *amd*T–102)[12] or by using glucose-free medium with 50 mM GABA as sole carbon source. Presumably, self nitrogen metabolite repression[12] limits GABA supplementation of *orn*B^{-} single mutants growing on GABA as sole nitrogen source. Neither L-glutamate nor L-aspartate supplements *orn*B^{-} auxotrophies.

The arginine/ornithine auxotrophies *orn*B–7, –8, –9, and –20 are markers in standard use[4]. *orn*B–300 was selected after ultraviolet mutagenesis of a strain of genotype *y*A–2 *al*X–4 *panto*B–100 (yellow conidial colour, lacking allantoinase, requiring pantothenic acid), using replica plating, as able to grow on a medium containing 5 mM GABA but not 5 mM L-proline as nitrogen source. *orn*B–300 is temperature sensitive, resulting in auxotrophy at 37 °C but not at 25 °C It is tightly linked to *orn*B–7, and they do not complement in diploids.

When diploids homozygous for *orn*B–7 are tested on the above media, *int*A^{c}–2 is partially dominant whereas *int*A^{-}–101 is recessive.

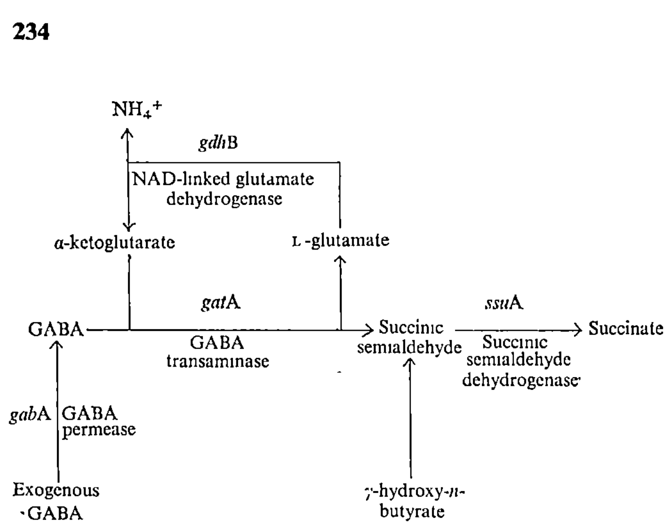

Fig. 1 The pathway of GABA catabolism in *A nidulans*, shown above, is probably very similar to that in *Escherichia coli*[21]. As expected[22–25] for compounds whose nitrogen is metabolised by way of L-glutamate before ammonium, GABA, β-alanine, and δ-amino-*n*-valerate supplement *gdh*A$^-$ mutants lacking the anabolic NADP-linked glutamate dehydrogenase, but are not utilised by *gdh*B$^-$ mutants lacking the catabolic NAD-linked glutamate dehydrogenase. GABA can also supplement *pyc*A$^-$ mutants[26] lacking pyruvate carboxylase and consequently requiring a source of a four-carbon dicarboxylic acid The utilisation of GABA is subject to both nitrogen metabolite[12] and carbon catabolite[27] repression (H. A. Penfold, C. R. Bailey, and H. N. A.).

expression. This type of evidence has also shown direct regulatory involvement of the *are*A gene product[7,12].

A full biochemical and genetical analysis of ω-amino acid catabolism and effects on acetamidase synthesis is in progress (H. A. Penfold, C. R. Bailey, and H. N. A., unpublished). We are particularly interested in seeing whether, as implied by results presented here, the binding of different effectors to the *int*A$^+$ product alters the relative efficiencies of expression of the three structural genes.

In conclusion, *int*A is a positive regulatory gene whose product directly affects the expression of three unlinked structural genes which can participate in different catabolic pathways. The structural genes code for an acetamidase, a GABA transaminase, and a GABA permease. At least the acetamidase is subject to an alternative, parallel mechanism of induction, involving the specific regulatory gene *amd*A, in addition to the induction mediated by the *int*A product. Therefore *int*A can be described as an integrator gene. The ability of (mostly point) mutations in *int*A to affect expression of any one or two or all three of the structural genes controlled by *int*A argues that *int*A is a single gene, not a battery of coordinately controlled contiguous genes. Of the alternative regulatory circuits offered by Britten and Davidson[1], *int*A therefore fits into the redundancy of receptor sites model rather than the redundancy of integrator genes model.

I thank Claudio Scazzocchio, Hugh Penfold, Keith Rand, Chris Bailey and especially Dick LePage for useful discussions and Bridget Pritchard and Mick Pierson for technical assistance, and the Royal Society for the Smithson Research Fellowship. This work was partially supported by a grant from the SRC to Professor J. M. Thoday.

Note added in proof: Confirming a crucial prediction, β-alanine and GABA induce acetamidase in wild-type but not in *inta*A$^-$-101 strains. β-alanine induces to a considerably higher level than acetamide, but simultaneous addition of β-alanine and acetamide results in only an intermediate, not an additive, level of induction. This probably indicates competition between the *int*A product (activated by β-alanine) and the *amd*A product (activated by acetamide) in the induction of acetamidase. Such competition could result from a partial or complete overlap of receptor sites.

X-ray study of the rubidium salt of ADP

ENZYMATIC reactions involving ATP and ADP require various metal ions as cofactors for catalytic activation. To understand the molecular mechanisms involved in these reactions it is important to know both the detailed geometry of these molecules and the way in which they bind to metal ions. Although numerous physical and chemical studies have been undertaken, particularly of divalent metal complexes in solution, the conformational and electronic aspects of these complexes are not fully understood. In the solid state, crystallographic studies have led to deductions on the conformations of ATP and ADP when bound to enzymes (refs 1–3 and H. C. Watson, personal communication) but the only crystal structures so far determined to atomic resolution are of the disodium salt of ATP[4] and the monorubidium salt of ADP[5]. The latter structure has so far only been published in part although some of its molecular features were reviewed recently[6].

The work reported here is on a different hydrate of monorubidium ADP containing one water molecule per nucleotide instead of three as in the earlier study. The Rb-ATP and ADP complexes are of biochemical importance as many enzyme systems associated with phosphate transfer require, in addition to divalent metal ions, univalent cations for activation (for example, K^+, Rb^+, NH_4^+)[7]. As part of our study of phosphate coenzymes we have attempted the preparation of single crystals of other mono- and divalent salts of ADP but so far without much success.

The monorubidium salt of ADP was crystallised as needles from water–alcohol solutions containing ADP free acid and RbBr (1:1). The solution was kept at 5 °C and *p*H 5.5 using Tris buffer. The space group ($P2_12_12$) and cell dimensions (a = 28.516(3) Å, b = 10.594(3) Å, c = 6.315(2) Å) agreed with those reported for the trihydrated rubidium salt by Muller and Deluke[5]. The measured density (D_m = 1.86 g cm^{-3}, D_x = 1.84 g cm^{-3}, Z = 4) indicated, however, the presence of only one water molecule per ADP molecule and this was later confirmed by the structure analysis.

A total of 1,440 unique reflections were collected on a

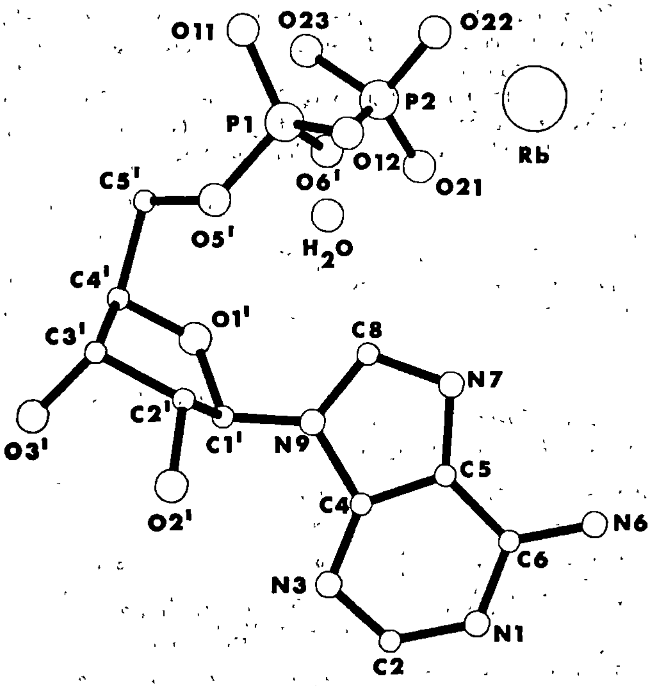

Fig. 1 View of the ADP molecule perpendicular to the base.

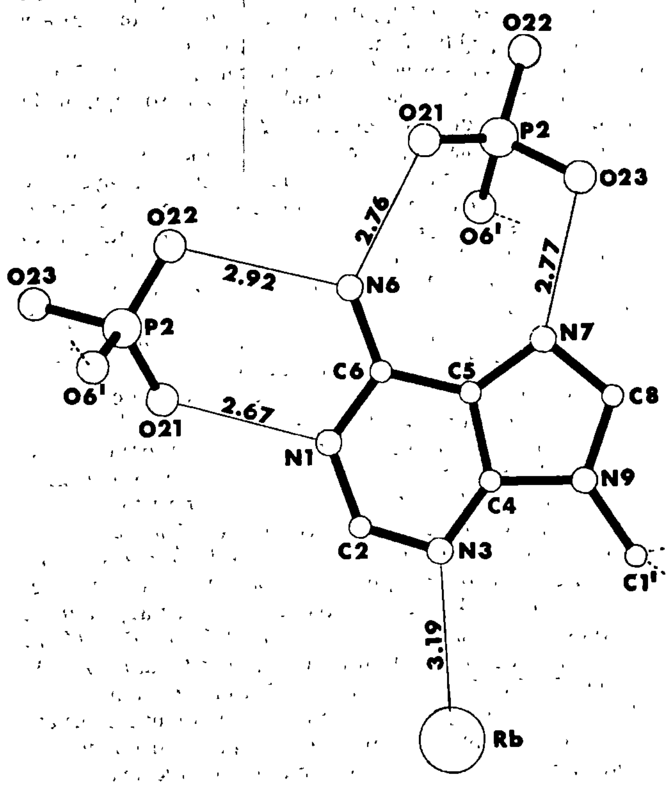

Fig. 2 Interactions involving the base atoms.

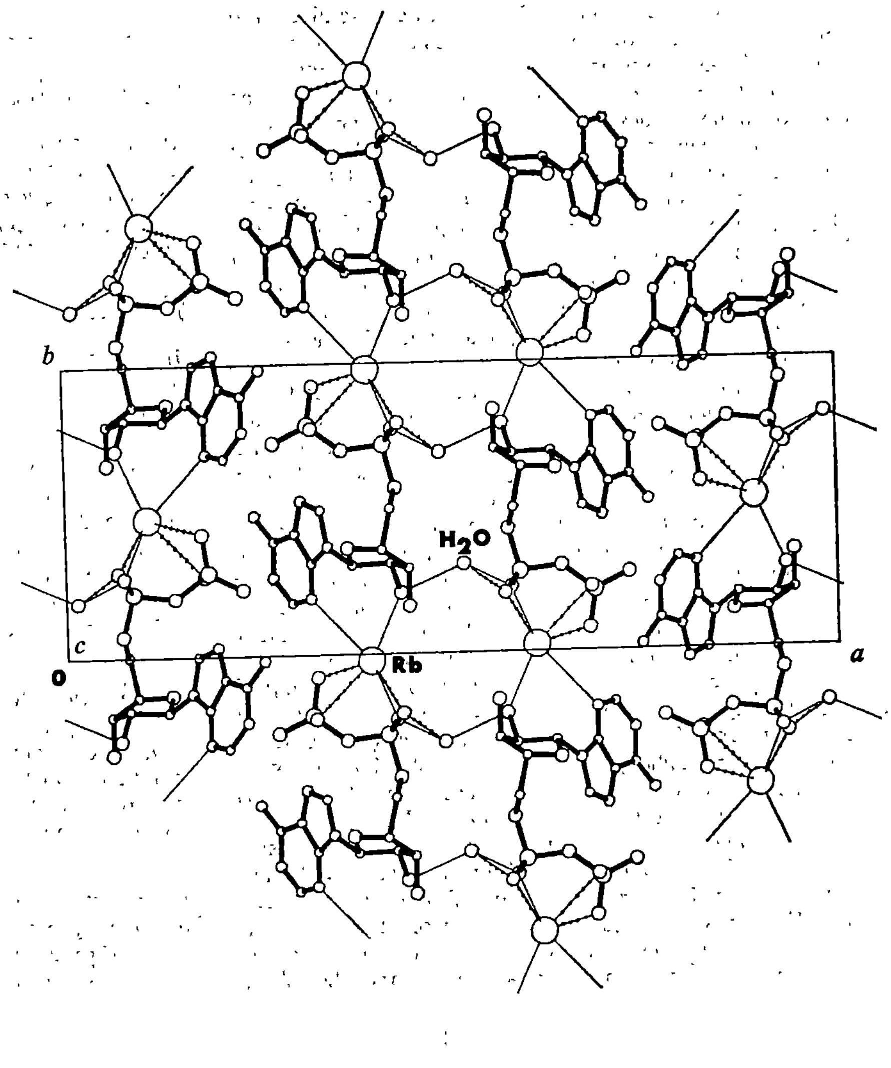

Fig. 3 Crystal packing viewed down the *c* axis showing the Rb$^+$ coordination and the hydrogen bonding with water molecules. (The dotted lines refer to contacts with molecules related by *c* translation.)

Syntex P2$_1$ diffractometer of which 1,200 were significant on the basis of $F > 3\sigma(F)$. The data were of moderate accuracy due to the poor quality of the crystal specimen.

The structure was solved by the application of MULTAN[8] and a difference Fourier synthesis and refined anisotropically in a full-matrix least squares program to $R = 11.9\%$.

A view of the molecule, perpendicular to the base, is shown in Fig. 1. The orientation of the base about the glycosidic C1′–N9 linkage is *anti*, the only conformation so far observed in the crystal structures of nucleotides. The dihedral angles O1′–C1′–N9–C8 and C2′–C1′–N9–C8 are 40.3° and −75.8°.

In the ribose ring, C2′ is displaced by 0.54 Å from the mean plane through C3′, C4′, O1′, C1′ corresponding to a typical C2′-*endo* puckering. The conformation about the C4′–C5′ bond is *gauche gauche* with torsion angles O5′–C5′–C4′–C3′ = 57.0° and O5′–C5′–C4′–O1′ = −63.3°. The conformation about C5′–O5′ is *trans* (P1–O5′–C5′–C4′ = 147.1°). A similar conformation has also been proposed as the predominant structure of ADP in solution, from a Fourier transform nuclear magnetic resonance (NMR) study[9]. The pyrophosphate moiety has a staggered conformation. A striking feature of the structure is the observed difference of 0.10 Å between the lengths of the two bridging bonds in the high energy linkage, which seems to be significant at the level of accuracy attained in the present analysis. The values for P1–O6′ and P2–O6′ are 1.54 and 1.64 Å respectively with an estimated s.d. of 0.02 Å. The angle P1–O6′–P2 is 135° (e.s.d. 1°). Corresponding values in other nucleoside diphosphates recently determined by us are 1.60 and 1.64 Å and 133° in cytidine diphosphocholine and 1.58 and 1.62 Å and 128° in cytidine diphosphoric acid[10].

In the crystal structure, the ADP molecule is folded but there is no Rb$^+$ bridge between the phosphate and adenine groups of the same molecule. Nor is there any evidence of other types of intramolecular interactions such as hydrogen bonding or metal binding between the pyrophosphate chain and the base or sugar moiety. In this respect, the ADP structure resembles the conformations found in the crystal structures of the dipotassium salt of uridine-5′-diphosphate (M.A.V., M. L. Post and O.K., unpublished) and the monosodium salt of cytidine diphosphocholine[10]. These coenzyme molecules, which are in very different crystalline environments, are also folded without any intramolecular metal ligation. They seem to take up the folded conformation preferentially and it is likely that any binding involving metal ions merely helps to stabilise the folded structure. A recent NMR study of ATP bound to lanthanide cations in aqueous solution[11] has been interpreted in terms of a folded conformation, with the lanthanide ion bound only to the β and γ phosphates but with no direct interaction with the purine ring.

It is interesting to note that in contrast to the folded conformation reported here, difference electron density maps suggest that ADP is in the extended form when bound to either lactate dehydrogenase[1] or phosphoglycerate kinase (refs 2, 3 and H. C. Watson, personal communication).

The extended crystal structure shows no self association between the bases through either hydrogen bonding, or base stacking. Instead there are two pairs of hydrogen bonds linking the adenine base to phosphate group of two neighbouring molecules (Fig. 2). One of these pairs has the Watson–Crick geometry, while the other involves the amino group and the imidazole nitrogen N7. These interactions and the binding of Rb$^+$ to N3 may be relevant to the recognition of the base by polar side groups of amino acids and metal ions in biological systems (to be published). The role of similar interaction in the sequence specific recognition of nucleic acids by proteins has recently been discussed by Seeman *et al.*[12].

Figure 3 shows the role of the Rb$^+$ ions and the water molecules. Each Rb$^+$ ion is bound to two ADP molecules through the negatively charged α and β phosphate oxygen atoms. The four Rb · · · O distances range from 2.85 to 3.33 Å. The sixfold coordination around Rb$^+$ is completed by N3 of the adenyl base of a third molecule at 3.19 Å and the ribose hydroxyl atom of the same molecule at 2.91 Å.

The water molecules lie in sheets perpendicular to the *a* axis interlinking layers of Rb–nucleotide complexes through hydrogen bonding.

The investigation was supported by the Indian Council for Medical Research, the MRC and the SRC (visiting fellowship to M.A.V. and provision of the diffractometer).

Corrigendum

In the article "Two short lived X-ray transients at high galactic latitude" by B. A. Cooke (*Nature*, **261**, 564; 1976) the scale and legend to Fig. 2*a* are in error. The scale should read 13 h not 3 h and the source designation in the legend should be A1353−40 not A0353−40.

Errata

In the article "Extinction-free measurements in crystallography" by A. McL Mathieson (*Nature*, **261**, 306; 1976), a sentence was omitted in the editing process. On line 12 of paragraph 1 mention of refs 5–7 should be deleted, and line 13 *et seq.* should read:

'. . . is applicable. The possibility exists of extrapolating to this condition, as a practical procedure, in relation to asymmetric reflection[5–7]. Starting with . . .'

In paragraph 4 line 7 of the right-hand column of page 307 'ref. 8' should be 'ref. 9', and in the caption to Fig. 2 the reference on the first line should be '5'.

In the article "Phosphorylation of yeast RNA polymerases" by G. Bell, P. Valenzuela and W. J. Rutter (*Nature*, **261**, 429; 1976) symbols were omitted from Fig. 1*a* which make it difficult to understand. The correct symbols are as follows. ^{32}P c.p.m. (○); RNA polymerase activity (●); Protein concentration (——).

In the article "Simple mathematical models with very complicated dynamics" by Robert May (*Nature*, **261**, 459–467; 1976) Figs 2 and 3 were transposed. The captions were in the correct position.

Introducing nuclear power

Lord Hinton of Bankside

Nuclear Power. (A Pelican Original) By Walter C. Patterson. Pp. 304. (Penguin: Harmondsworth, Middlesex, March 1976.) 80p.

WALTER PATTERSON'S book is written in two parts. The first, which he calls "The World of Nuclear Fission" is excellent, I have never read a better simple explanation of the theory and practice of nuclear reactors and their ancillary plants. I am less enthusiastic about the second part of the book, most of which deals with the hazards of nuclear power. It seems to me that, in his anxiety to make a case which is real, Patterson may be guilty of lack of balance. The impression which is given by the italic printing of some paragraphs is that they have been abstracted from official reports; my limited inside knowledge contradicts this impression. For instance, I have never heard the filters on the Windscale piles referred to as "Cockcroft's folly". The stacks had not been built (as stated in italic script) when information from America made it clear that filters were a necessary precaution.

These statements are, in themselves, of minor importance but they throw some doubt on italic accounts of other incidents. The italic paragraph about "the dramatic gesture of pouring away milk" after the Windscale incident seems to be romanticised; I had left the UK Atomic Energy Authority at the time of the incident and knew nothing of any discussions that took place but (although the milk could safely have been used in milk chocolate or as dried milk) it seems to me that it would have been a foolish firm which bought the milk and laid itself open to the unfounded accusation of selling a radioactive product. The italic paragraphs about the Enrico Fermi fast reactor and mention of the "China syndrome" are hardly a fair argument against the fast reactors which are being designed today and which use a ceramic and not a metallic fuel.

The book does not emphasise the world's real need for nuclear power. The rate of usage of exhaustable natural resources does not increase exponentially to a sharp peak and suddenly fall away to nothing; it conforms to a wave-shaped curve so that at some point in time growth becomes steadily slower until a peak is reached; and, thereafter, growth becomes negative (that is, the rate of usage diminishes).

There is good evidence to suggest that global resources of fossil fuels are such that we shall pass over the peak of such a curve at about the end of this century. It is highly improbable that renewable energy resources (wave power, solar energy and wind power) can make up the deficit; without nuclear power it is almost certain that standards of living will fall.

Nuclear power does give rise to some hazards but nothing in this world is absolutely safe. Nuclear power plants can be made as safe or safer than very many other industrial plants provided that engineers are not over-ambitious in extrapolating either the design parameters or the size of the construction programs With these reservations I would sooner accept the hazards of nuclear power than the risk of an energy famine.

The first part of Walter Patterson's book is an outstandingly good introduction to nuclear power for the intelligent layman. As a reminder of their responsibilities, Part 2 should be compulsory reading for those men who have responsibilities in the nuclear power industry; but its lack of balance may give a wrong impression to the lay-reader. ☐

Lord Hinton of Bankside is Deputy Chairman of the Electricity Supply Research Council and was formerly Managing Director (Industrial Group) of the UKAEA and Chairman of the UK Central Electricity Generating Board.

Macrophage house of fashion

Immunobiology of the Macrophage. Edited by David S. Nelson. Pp. xviii+633. (Academic· New York and London, April 1976.) $39, £21.45.

As the hemlines of Western ladies rise and fall and split and waver with each new season's modish rhythm so do the fads and fancies of immunologically orientated biologists Thus lymphocytes were 'discovered' in the sixties and are probably presently at their apogee of man-hour involvement. The macrophage was discovered at the turn of the century but, as Cohn puts it in the Introduction to this fascinating book, the doldrums soon descended on all but a few dedicated phagists. The book heralds the new golden age of the macrophage (compare Golden Age of Thymology; Miller, *Lancet*, **2**, 1299; 1967).

Some of the 24 chapters, each written by a different expert in the field, deal with macrophage involvement in various *in vitro* cell preparations; others with the heterogeneity of macrophages as determined by their site of origin and the complexities of their cell surfaces. The responses of macrophages to chemotactic factors and their capacities to produce and liberate factors which affect other cellular components of the immunological orchestra are described Many are the schemes of cell interaction. The papers by Volkman on monocytes, by Evans and Alexander on macrophage cytotoxicity, by Holtermann *et al.* on immunotherapy of skin tumours and that by Territo and Cline on macrophage disorders in man are all at the end of the book and all well worth reading.

The changes of tempo and topic make me long for the earlier one-man macrophage book of Nelson but he, although remaining an editor, has abandoned the role of a colossus in the field capable of comprehensive review. In spite of this dereliction of function it is Nelson's summarising chapter 9 and final short chapter which are most useful to the outsider. As he says "In the evolution of our complex mammalian system they (macrophages) seem almost ubiquitous, emerging from obscurity to make some lysozymes contribute to the complement system, help a T cell, present a stimulus to a B cell, or quell an unruly mutant."

Those with time and deep pockets (do all books cost £20 these days?) should buy this book. It is well produced, well edited and most informative. But perhaps more important its mastery will put you in on the ground floor of the current macrophage house of fashion.

A. J. S. Davies

Laser physics

Laser Spectroscopy: Proceedings of the Second International Conference, Megève, June 1975. (Lecture Notes in Physics, Vol. 43). Edited by S. Haroche, J. C. Pebay-Peyroula, T. W. Hänsch and S. E. Harris. Pp. x+468. (Springer: Berlin and New York, 1975.) DM 45; $18.50.

THE development of tunable laser systems has radically altered the nature of atomic and molecular physics. Used in conventional spectroscopy, the high intensity and monochromaticity of the tunable laser makes it an ideal probe of purely atomic properties such as excited state lifetimes, fine and hyperfine structure splittings and isotope shifts: the list of worthy results is endless. When the laser is used in a dynamic sense, new and exciting non-linear, intensity-dependent features emerge. Finally the extremely short duration of pulses generated by pulsed mode-locked lasers enables the photochemist to study ultrafast relaxation and transport mechanisms. This volume, demonstrates how laser spectroscopy has arrived at a semblance of maturity after a period of very rapid growth. The topics discussed here extend from the quantum electrodynamics of laser resonance fluorescence to laser isotope separation processes of economic importance. Invited papers presented at the conference are here printed directly from the authors' typescripts.

For me, some especially interesting papers were those of Cagnac on high resolution, two photon spectroscopy, Mollenauer on colour centre lasers, and Cohen-Tannoudji's review of the currently fashionable dynamic Stark effect in resonance fluorescence. Workers in laser physics or atomic physics will find much in this volume to entertain and to stimulate One fascinating feature is the large number of papers, some with carefully spelled-out background histories and dates, devoted to laser isotope separation. On this the editors make the curious comment: "Unfortunately, the free flow of information was here still severely hampered by secrecy and classification, and the wisdom of including such a 'political' topic in the program has since been seriously questioned".

No doubt some of the new results presented at the conference for the first time will either appear or already have appeared elsewhere in the literature. But as a review of the status of the field, this volume serves a very useful purpose and can be recommended to workers in atomic and laser physics.

Sound basis for plant virology course

Plant Virology: The Principles. By Adrian Gibbs and Bryan Harrison Pp. x+292. (Arnold: London, March 1976.) £16.

IN the Preface to this excellent book the authors describe its gestation period as 'lengthy', which is scarcely more informative than a piece of string; but as they state that they aimed to provide a text at the university teaching level, a need not filled by books which have since appeared, I suppose that this one grew from notes prepared for lectures given to students of the Imperial College, University of London, by Gibbs and Harrison some 10 years ago while they were both at Rothamsted. This speculation is relevant to an assessment, since a gestation period of several years would account for some characteristics which might otherwise puzzle or even irritate a reader I am not suggesting that the book is out of date; far from it; I am referring to differences between chapters in style and depth. Problems of selection would have grown erratically as reference lists lengthened because research papers proliferated on fashionable topics; as the cost of publication rose at an accelerating rate, hard choices would have to be made.

The layout of the book provides a sound basis for a lecture course for undergraduates. After the history and scope of plant virology, some groups of viruses and the cryptogram system are described, followed by accounts of virus effects on plants, and methods of experimental transmission. The next chapter deals with the composition and structure of plant viruses in considerable depth and seems over-elaborate compared with others Purification and properties are well covered in chapter 6, although the use of liquid nitrogen and of polyethylene glycol in extraction seem strange omissions. Assay methods are clearly described in three chapters separately considering infectivity, serology and physicochemical methods. After chapters on effects of inactivation and behaviour of viruses in plants, one on variation, strains and classification seems misplaced between them and those on means of transmission, ecology and ways of preventing crop losses. In my view, part of the penultimate and all of the final chapter should have been omitted and the space used to expand those chapters which seem unduly compressed—for example, 'Effect of Viruses on Plants'; the subjects in question are 'Viruses of Animals' and 'Plant Pathogens Confused With Viruses'.

The production is excellent (as befits its price), with clear type and illustrations and agreeably few typographical errors. I regret the absence of titles from the references, making it laborious to check that all are worth inclusion; one suspects that the authors' assurance that, in spite of their selection having been "somewhat arbitrary, most important papers are included," refers mainly to those by themselves and co-workers; otherwise the choice might best be described as whimsical.

The authors have disregarded their own warning in at least one instance. They rightly stress the hazards of identifying viruses on inadequate data, yet they apply the name "swollen shoot" to a virus of cacao trees in Trinidad. To the best of my knowledge, this and the West African swollen shoot virus have no established affinities besides a common vector.

Unquestionably this book is a valuable addition to the few on plant viruses and will be welcomed especially by the small band who teach the subject at English-speaking universities.

A. F. Posnette

Islamic science

Islamic Science: An Illustrated Study. By Seyyed Hossein Nasr. Pp. xiv+273. (World of Islam Festival: London, 1976.) £12.50.

A HANDSOME book, with 135 colour plates and 94 black-and-white pictures and diagrams, the photographs mostly by Roland Michaud. As for Seyyed Hossein Nasr's text, it may be recommended to those who already know enough about the subject to make allowances for the author's lack of objectivity and not to be led astray by his inaccuracies and his Humpty-Dumptyish way with words. Many of the author's convictions are shared by all reasonable people. But what the reader must bear in mind is that, although the implied contrast throughout is between the Islamic and non-Islamic worlds, what the author is really contrasting is the modern virtually world-wide technological civilisation on the one hand and an idealised Islamic Golden Age on the other. "In contrast to the modern situation, in traditional technology, of which many examples can still be seen in the Islamic world, the maximum possible recycling of all materials has always been the rule rather than the exception . . . The use of every part of the sheep for purposes as far apart as feeding the family to providing fertiliser for the land to making strings for musical instruments is a case in point" (p234). A case in point indeed; it was no less true in eleventh-century Birmingham than in eleventh-century Baghdad.

Photo: Roland Michaud

Contemporary Persian alchemist at work

The central thesis of the book seems to be summed up on p150: "Islamic civilisation had the means to make complicated machines and apply them to the problems of the daily life of the Islamic community. But like the Chinese, who made gunpowder but never made guns, the Muslims never took that step which would mean the creation of a technology out of harmony with the natural environment." The comparison with China, by the way, would be more acceptable if the previous page were not devoted to illustrations from Muslim works on the manufacture of cannon. Medieval Muslim men of science did not invent the steam-engine or the dynamo; nor did their Christian contemporaries, and no discredit to either party for that. But can one ascribe this failure to a conscious self-denying ordinance? It seems an affront to the genius of such men as al-Biruni and Ibn al-Haytham to suggest that they were less willing than any Western savant "To follow knowledge like a sinking star, Beyond the utmost bound of human thought."

As for the other faults alluded to above, one example of each must suffice. "In Islam animals are never 'slaughtered'; they are only allowed to be killed ritually (*dhibh*)" (p244; for *dhibh*, incidentally, read *dhabh*). This will be about as meaningful to most readers as saying "In France people never 'drive' cars; they only conduisent them".

"In Islamic sources the one Hermes of Alexandrian sources became three, hence the term Hermes Trismegistos (from the Arabic *al-muthallath bi'l-hikmah*) . . . " (p198). As the term was in use in the early third century, 400 yr before the coming of Islam, either Dr Nasr is wrong or someone in the Hellenistic world deserves credit for a remarkable piece of intelligent anticipation.

One feels a little mean at criticising so urbane a guide to Cloud-cuckoo-land; with caution on the part of the reader, this is a useful book. Even without, it is very beautiful.

G. L. Lewis

Petroleum geology of North American continental shelves

Canada's Continental Margins and Offshore Petroleum Exploration. (CSPG Memoir No. 4.) Edited by C. J. Yorath, E. R. Parker and D. J. Glass. Pp.898. (Canadian Society of Petroleum Geologists: Calgary, Alberta, 1975.) $19.

THIS excellent book is unfortunately misnamed, and may be ignored by European geologists (and especially petroleum geologists), for whom it may be very useful. Essentially this volume describes the geology of the continental shelves of North America, from Vancouver on the west coast to Florida on the east coast, of the Arctic Shelves adjacent to Canada, Greenland, Svalbard and Russia, and of the Eastern Atlantic shelves from North Cape to Morocco. These areas are described on the basis of geophysical maps, sea-bed sampling, sparse well control and adjacent onshore geology. These data are interpreted in the light of plate tectonics theory, and most papers review the petroleum prospects in the areas concerned.

The volume contains 50 papers which were presented at two symposia: the *Offshore Symposium* held at St John's, Newfoundland in May 1974, and in Calgary, Alberta in September of the same year. The editors took the view that it was more important to publish the book in haste, with minimal editing, rather than to delay publication for careful editing and preparation. This was probably the correct decision. A page of errata is included; there seem to be few misprints. Because of this haste there are maps without scales (for example, p301, 302, 304, 309), metres and feet get used for vertical depths on facing pages in the same paper (p570, 571), some microphotographs have no scale (p626), some ornaments are not explained in keys (p651), and some gravity maps lack contour values (p304). Although the editors claim to have checked references for ease of retrieval, I defy anyone to track down those listed on p852.

Much of the material is new, at least to this reviewer. Some of the North American east coast data have been published previously in the bulletins of the American Association of Petroleum Geologists, and even of the Canadian Society of Petroleum Geologists itself. Similarly the material presented on the continental shelves of north-western, Europe will be familiar to those who have read *Petroleum and the Continental Shelf of North-west Europe*, edited by A. W. Woodland (for review, see *Nature*, **259**, 607; 1976).

On balance, however, the editors are to be congratulated for having collated so much data on such a wide area from so many sources. This volume will provide a valuable source book for geologists, and especially petroleum geologists who are interested in the continental shelves of North America, the Arctic and Europe.

R. C. Selley

obituary

David M. Dennison died on April 3, 1976 at his home in Ann Arbor, Michigan. He was born on April 26, 1900 in Oberlin, Ohio, and, except for various leaves of absence, spent his whole academic career at the University of Michigan, where he joined the faculty in 1927. He was chairman of its Physics Department from 1955 to 1965 and retired in 1971. He was a member of the National Academy of Sciences, a Fellow of the American Physical Society and the recipient of various honours.

With his death, the world of Physics loses again one of that small number of pioneer theorists who made early basic contributions to quantum mechanics and to the understanding of the structure of matter, contributions which today are regarded as self-evident. Dennison obtained his Ph.D. in 1924 from the University of Michigan, where Harrison M. Randall and coworkers were using powerful new techniques for the observation of the infrared spectra of molecules. Dennison then spent three years visiting various physics centres in Europe. In 1926, when he was in Cambridge studying with R. H. Fowler, he proved that the hydrogen nucleus has a spin whose magnitude was half that of a quantum of rotation. That this nucleus might have a spin had been talked about widely, but no evidence had been presented. It is the more remarkable that Dennison's proof did not come from spectroscopic data, but from the study of a baffling anomaly in the variation with temperature of the specific heat of hydrogen. Dennison showed that the two configurations of the hydrogen molecule, one with parallel, the other with opposite nuclear spins, must be considered as two separate gases and that transitions from one into the other are very rare. This gave a complete quantitative explanation of the specific heat anomaly as well as a clarification of spectral data. That the volume ratio of the two gases had to be taken as three to one determined the value of the spin. The recognition of these two forms of hydrogen has today found an important use in the long-term storage of liquid hydrogen.

Another remarkable contribution made by Dennison in 1932 concerns the ammonium molecule NH_3. In this molecule the nitrogen atom is in the centre of the triangle, but just outside the plane, formed by the three hydrogen atoms. Dennison noted that a quantum mechanical effect makes it possible for the nitrogen to 'leak' through to the other side. The details were worked out in collaboration with G. E. Uhlenbeck, also at Michigan. It was shown that this non-classical effect caused the molecule to absorb radiation of ~1.5-cm wavelength, which might be produced by miniature magnetrons. Dennison inspired N. H. Williams and C. E. Cleeton at Michigan to attempt a unique experiment to detect this absorption. It was successful and represents the first experiment in microwave spectroscopy. During the second world war, Dennison collaborated with a group developing proximity fuses. Afterwards he spent some time together with T. H. Berlin computing orbits for the Michigan electron accelerator, though his primary interest remained the quantum theory of molecular structure and the interpretation of their spectra to which he contributed many important advances.

David Dennison was an excellent teacher with a genuine concern for students. He was a modest person, who never lost his temper and had many interests outside the field of physics. He was a fine scholar, a helpful friend with whom it was a great and beneficial pleasure to discuss all sorts of problems.

Samuel A. Goudsmit

Hans Thirring, Professor emeritus at Vienna University, died on March 22, 1976. He held the chair of Theoretical Physics from 1927 to 1958, except during the time of the Nazi regime when he was dismissed because of his pacifist convictions.

Thirring's scientific work dealt mainly with problems in general relativity. The prediction of the 'Thirring-Lense effect' is widely known. He also made important contributions to the quantum theory of specific heats. His 3-yr course on theoretical physics was an excellent example of how to present complicated material in a crystal clear way, and many generations of young physicists profited greatly from his outstanding teaching.

During World War 2 Thirring's thinking concentrated on the question how to achieve a peaceful world. The horrific prospects of nuclear warfare stimulated his activities. Thirring was the first to predict openly the feasibility of a hydrogen bomb, in his book *Die Geschichte der Atombombe* (1946). His further book, *Homo Sapiens,* outlined an educational and psychological way to a world without aggression, hatred and war. He was realist enough to expect not too much effect on mankind from the written word alone, and be put his convictions into practice. He was one of the pioneers of the Pugwash movement and he considered this free community of scientists of high reputation from all nations as one of the few hopeful developments towards peace in his time and for the future.

P. Weinzierl

announcements

Appointments

Professor **Frans E. Wickman** has been elected President of the Royal Swedish Academy of Sciences.

Dr A. Bull has been appointed to the second Chair in Applied Biology at the University of Wales, Cardiff.

Dr Ernest Ambler has been appointed the new Director of the National Bureau of Standards.

Professor Robert F. Whelan has been appointed Vice-Chancellor of the University of Liverpool.

Professor Francois Gros has been appointed as Director of the Institut Pasteur.

Dr Donald D. Brown will become the Director of the Carnegie Institution of Washington's Department of Embryology to succeed **Dr James D. Ebert** who is moving to the Marine Biological Laboratory in Woods Hole as the full-time President and Director.

Awards

The German Pharmacological Society has given the Schmiedeberg-Plakette to **Dr Hans Kosterlitz** of the University of Aberdeen for his work on opiate receptors.

Sir Karl Popper has been elected a Fellow of the Royal Society.

The IMO Prize has been awarded to **Academician Evgeny K. Fedorov** of the Institute of Applied Geophysics of the Academy of Sciences of the USSR

Sir James Lighthill and **Dr Max Perutz** have been elected associate members of the French Academy.

Meetings

August 18–21, **Convention of the Western Amateur Astronomers,** San Diego (PAA Reservations, PO Box 505, San Marcos, California 92069).

August 30–September 2, **The Physics of X-Ray Spectra,** Gaithersburg, Maryland (Dr W. G. Schweitzer, Physics Building, Room B164, NBS, Washington DC 20234).

August 30–September 3, **4th Symposium on Recent and Fossil Marine Diatoms,** Oslo (Dr G. R. Hasle, Department of Marine Biology and Limnology, University of Oslo, PO Box 1069 Blindern, Oslo 3, Norway).

September 5–10, **Cell Biology,** Boston (The Secretary, First International Congress on Cell Biology, PO Drawer ICCB, Boulder, Colorado 80302)

September 6–8, **5th European Drosophila Research Conference,** Louvain-La-Neuve (Professor F. A. Lints, Laboratoire de Génétique, Université de Louvain, Place Croix du Sud 2, B-1348 Louvain-La-Neuve, Belgium).

September 6–8, **Lipid Biochemistry,** Paris (J. Polonovski, Faculté de Médecine Saint-Antoine, 27 rue Chaligny, 75571 Paris Cedex 12, France).

September 6–10, **Soil Organic Matter,** Braunschweig, FRG9 (The IAEA, Kärtner Ring 11, PO Box 590, A-1011 Vienna, Austria).

September 13–24, **Oceanography,** Edinburgh (The Organising Committee, Joint Oceanographic Assembly 1976, c/o The Royal Society of Edinburgh, 22 George Street, Edinburgh EH2 2PQ, UK).

September 14–16, **Powder Coating,** Cincinnati (AFP/SME, 20501 Ford Road, PO Box 930, Dearborn, Michigan 48128).

September 14–17, **Nutrition,** Munich (Dr Angelika Janssen, Organisation Secretary, 2nd European Nutrition Conference, Medizinische Poliklinik der Universität München, Pettenkofterstrasse 8a, D 8000 München 2, FRG).

September 14–17, **3rd Symposium on Pharmacology of Thermoregulation,** Banff, Alberta, Canada (Prof. K. E. Cooper, Division of Medical Physiology, Faculty of Medicine, The University of Calgary, Calgary, Alberta, Canada T2N 1N4).

September 15, **DNA Repair and Late Effects,** Vienna (Institut für Biologie, Forschungszentrum Seibersdorf, A-244 Seibersdorf, Austria).

September 19–22, **Gallium Arsenide and Related Compounds,** Edinburgh (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX).

September 20–24, **Thermal Analysis,** Salford (Dr D. Dollimore, Department of Physical Chemistry, University of Salford, Salford M5 4WT, UK).

September 22–24, **Turbulence in Liquids,** Rolla, Missouri (Turbulence Symposium, Extension Division, University of Missouri-Rolla, Rolla, Missouri 65401).

September 23–24, **Symposium on Ecological Effects of Pesticides,** London (Institute of Biology, 41 Queen's Gate, London SW7 5HU).

September 24–26, **Instrumentation for Synchrotron Radiation,** Daresbury (Mrs S. A Lowndes, Daresbury Laboratory, Warrington WA4 4AD, UK).

September 27–29, **Wetting, Spreading and Adhesion,** Loughborough (Dr R. J. Akers, Department of Chemical Engineering, University of Technology, Loughborough, Leicestershire LE11 3TU, UK).

October 3–9, **Hill Land,** Morgantown (R L Reid, Hill Land Symposium Committee, College of Agriculture and Forestry, West Virginia University, Morgantown, West Virginia 26506).

December 2–9, **Pharmacology,** Buenos Aires (VI Congreso Latinoamericano de Farmacologia, Junin 956-5° piso, Buenos Aires, Argentina).

March 7–11, 1977, **Tropical Ecology,** Panama (Dr Reina T. de Araúz, President, Organising Committee, IV International Symposium of Tropical Ecology, PO Box 662, Panama 1, Rep. of Panama)

March 7–11, 1977, **Biologically Active Polypeptides,** Montbello, Quebec (CBS-CIC 1977 Joint Symposium, 151 Slater, Suite 906, Ottawa, Ontario K1P 5H3, Canada).

March 30–April 1, 1977, **Cybernetics of Movement and Classification,** Munich (Univ.-Doz. Dr G. Hauske, Lehrstuhl für Nachrichtentechnik der Technischen Universität München, Arcisstrasse 21, D-8000 München 2, FRG).

April 24–30, 1977, **Radiation Protection,** Paris (Mr Gilbert Bresson, General Secretary, IRPA IVth International Congress, B.P.33, 92260-Fontenay-aux-Roses, France).

May 2–5, 1977, **Cytology,** Tokyo (A. Meisels, MD, FIAC, General Secretary, 6th International Congress of Cytology, 1050 Chemin Ste-Foy, Quebec 6, P.Q., Canada).

June 19–25, 1977, **Inborn Errors of Metabolism in Man,** Tel Aviv (Scientific Secretariat, Dr O. Sperling, PO Box 16271, Tel Aviv, Israel).

June 27–July 1, 1977, **Amorphous and Liquid Semiconductors,** Edinburgh (Conference Secretariat, Centre for Industrial Consultancy and Liaison, University of Edinburgh, 14 George Square, Edinburgh EH8 9JZ).

July 3–8, 1977, **Immunology,** Sydney (The Secretary General, 3rd International Congress of Immunology, PO Box 391, Darlinghurst, N.S.W. 2010, Australia).

July 11–14, 1977, **Dendrochronology in Northern Europe,** London (The Organising Secretary, Symposium, National Maritime Museum, Greenwich, London SE10 9NF).

August 7–13, 1977, **General Relativity and Gravitation,** Waterloo, Ontario (GR8, Applied Mathematics Department, University of Waterloo, Waterloo, Ontario N2L 3G1, Canada).

September 5–8, 1977, **New Processes of Waste Water Treatment and Recovery,** London (Deadline for abstracts: December 31), (Dr D H. Sharp, General Secretary, Society of Chemical Industry, 14 Belgrave Square, London SW1X 8PS, UK).

September 5–9, 1977, **Hypoxic Cell Sensitisers in Radiobiology and Radiotherapy,** Cambridge (Dr G. E. Adams, CRC Gray Laboratory, Mount Vernon Hospital, Northwood, Middlesex HA6 2RN, UK).

September 6–11, 1977, **11th World Congress of Neurology,** Amsterdam (Secretariat, c/o Holland Organising Centre, 16 Lange Voorhout, The Hague, The Netherlands).

September 13–16, 1977, **Nuclear Quadrupole Resonance Spectroscopy,** Osaka, Japan (4th International NQR Symposium, Faculty of Science, Osaka University, Toyonaka 560, Japan).

Autumn, 1977, **Phosphate Compounds,** Rabat, Morocco (Mr M. Kabbaj, Director of Technical Research, Institut Mondial du Phosphate, 8 rue de Penthièvre, 75008 Paris, France).

Person to Person

Scientist going on sabbatical from Jerusalem would like to exchange flats with someone in London. Four-room flat (3 bedrooms), central heating and all conveniences with schools nearby near the Hebrew University (Beit Hakerem). Available mid-August 1976 for 12 months (Dr S. Moshkovitz, Geological Survey, 30 Malkhei Street, Jerusalem, Israel.)

NASA is seeking proposals for scientific investigations of Jupiter, to make *in situ* (by probe) and remote measurements (by orbiter) of the planet, its environment and its satellites. Primary emphasis is on direct entry measurements and the characterisation of the magnetosphere of the planet and its interaction with the satellites. Proposals for the Probe investigations by November 1, 1976, and for the Orbiter investigations, December 1, 1976 to Dr M. A Mitz, Chief, Advance Planning, Lunar and Planetary Programs Office, Code SL, NASA Headquarters, Washington, DC, 20546.

A seminar on Scientific and Technical Publishing in a Multilingual Society is being held in Luxembourg by the Commission of the European Communities on November 11–12, 1976. The chief aim is to generate proposals for measures which might be taken in the framework of the European Community. For further information contact Mr J. M. Gibb, D.G. XIII, European Centre, Kirchberg, Luxembourg.

The David Anderson-Berry prize will be awarded for recent work on the effects of X-rays and other forms of radiation on living tissues. Published work will be taken into consideration if submitted with the application In addition to direct application for the Prize, proposals may be made on behalf of others. Applications and proposals must be in the hands of the General Secretary, Royal Society of Edinburgh, 22/24 George Street, Edinburgh EH2 2PQ, Scotland, not later than September 30, 1976.

The Bigfoot Research Society is looking for organisations willing and able to analyse specimens hoped to be collected during field studies of this shy animal. Write to: James R. Spink, Bigfoot Research Society, PO Box 61-1564, North Miami, Florida 33161.

Sydney–Paris. Wanted, two- to three-bedroom furnished flat or house within commuting distance of Meudon-Bellevue (Paris) in exchange for a three-bedroom furnished house in Lindfield (13 km N of Sydney) for approximately 1 yr beginning during September 1976. Dr D. M. Eagles, National Measurement Laboratory, CSIRO, Chippendale, NSW 2008, Australia.

ACCOMMODATION: Scientist going on sabbatical leave to Orsay offers exchange of comfortable three-bedroom house in Peterborough, Ontario, Canada for a similar one in the southern or south-eastern suburbs of Paris from September 1, 1976 to August 31, 1977. Please contact Professor R. Alfred, Physics Department, Trent University, Peterborough, Ontario, Canada.

There will be no charge for this service. Send items (not more than 60 words) to Martin Goldman at the London office. The section will include exchanges of accommodation, personal announcements and scientific queries We reserve the right to decline material submitted. No commercial transactions

Out of work in Argentina

THE letter (page 253) from more than 60 Italian scientists drawing the scientific community's attention to the situation in Argentina is a grim reminder of the difficulties surrounding university and government institutional work on a continent which for many of us in the Anglo-Saxon world is still remote and in some way unreal.

The intellectual in Argentina has never been as secure as his counterpart in West Europe and North America. Universities have been watched very closely by successive governments, and the appointments of rectors and deans have often been purely political affairs As a result there has been a steady trickle of emigrants to more secure territory—a trickle that has sometimes swelled to a flood (in 1966, for instance, 1,100 found themselves out of a job). The turnover in university staff has been accordingly immense; one academic in Britain, who has fairly strong ties with Argentina, remarked that almost every Argentinian scientist he had known had been forced, at some time, to leave. The quality of young people coming up through the major universities is, it is widely agreed, suffering as a result.

Argentina's problems in recent years have, of course, gone much deeper than instability in universities and there was genuine hope when General Videla came to power that he would be able to act against the terrorism which had led to so much indiscriminate killing. To a certain extent he has succeeded because terrorism by the left has been sat on very firmly; however, right-wing activities do not seem to have been significantly restrained. The bewildering variety of competing security organisations and the divisions within the armed forces add to the complexity of the situation. An exiled Argentinian commented that knowing how one stood in La Plata would not necessarily make one safe in Buenos Aires, and so on. It is small wonder that universities have become places of fear and that gun-carrying soldiers are in evidence.

If recent dismissals are, in general, politically directed against the left, they are not universally so; several well known right wingers have also been relieved of their posts. What seems to have happened is that the government, faced with a truly depressing economic situation requiring urgent international support, and forced to make major cuts in public expenditure, has used the opportunity to thin its ranks of those who have taken up certain political stances in the past. Those who have steered clear of politics or who openly support the Junta can survive, though in somewhat straitened circumstances.

It used to be that, with families widely spread over South America, people in trouble could move over to Chile, Uruguay or Paraguay. Indeed Uruguay was often called the Switzerland of South America. No longer; the Uruguayans in their zeal to stamp out the Tupamaro guerillas seem to have 'processed' an extraordinary large proportion of the population and to have allowed torture to become rampant. The fate of the mathematician Jose Massera who has been imprisoned since last October and has suffered some grievous injuries is likely to deter most academics from choosing to move over to Montevideo.

The pressure, then, is really on the wider community of scientists to continue to absorb where necessary or, even more, just to keep in touch—a plea made most simply and expressively by the writers of the letter. From the Europe–North American axis it is very easy conveniently to forget the difficulties of doing science elsewhere, to look down on scientists struggling with poor facilities and heavy teaching loads, and to ignore colleagues off the axis when passing round the gossip, the early warnings, the bits of advice. Even well endowed Australians, with regular jet flights to the Northern Hemisphere, know that. How much more so does the problem afflict Argentinians, and how much more must we simply not stand by uninterested. □

Why are we waiting?

ALTHOUGH Mr Mulley, UK Secretary for Education and Science, has had the report of the Williams Working Party on Genetic Manipulation of Micro-organisms on his desk for well over a month, it is due to remain there for at least a "few more weeks". Until then scientists will be in the dark over the details of the code of practice that will apply to recombinant DNA research in Britain. There are several possible excuses for Mr Mulley's tardiness. None of them is good enough.

The Williams Working Party had its origins in a statement published by Professor Paul Berg and his colleagues in July 1974 in which they expressed concern at some of the possible consequences of the research they themselves had pioneered. The improbable pathway to disaster that they foresaw involved the escape from laboratory containment of bacteria whose genes had been experimentally recombined with genetic material from another organism, the survival of those bacteria in the outside world, their colonisation of the human intestine and the expression of their foreign genetic component to the detriment of the human host.

That scenario was taken seriously enough on both sides of the Atlantic that most scientists have since held to a voluntary moratorium on suspect research. American concern, latterly under the auspices of the National Institutes of Health, culminated four weeks ago in the issue of a complex series of guidelines. The British wheels were set in motion in July 1974 with the Ashby Working Party, convened by the Advisory Board for the Research Councils, which reported in December of that year. Seven months later Mr Mulley set up the Williams Working Party to produce a code of practice and to consider the establishment of a central advisory service for laboratories carrying out the procedures in question.

The Williams Working Party report is unlikely to contain many surprises. It will not recommend the proscription of any particular experiments but will suggest the precautionary measures that are appropriate for various categories of research. Few specific experiments will be quoted and no attempt to quantify their dangers will be made. The report is expected to endorse Ashby's suggestion of a central advisory service and to recommend how it might operate.

The scientific community anxiously awaits the report and Mr Mulley's reactions to it. The longer they have to wait for a go-ahead on experiments which in some cases have been on ice for two years, the worse (whatever the precautions suggested) will become the atmosphere of frustration and suspicion that has gradually built up. Inevitably moratorium-breaking has already occurred, and the consequences for those involved have on occasion been unpleasant.

Why then is Mr Mulley keeping us waiting? One possibility is that he is reserving the right to modify his reactions in the light of the response at home and abroad to the American guidelines. If so the delay could well be lengthy in view of the recent clash between Cambridge (Massachusetts) City Council and Harvard University. The trouble arose when the Mayor of Cambridge attempted to block plans to build a high containment laboratory within the Harvard Biological Laboratories; at the moment there is a three-month moratorium during which the council will review the position before deciding on the future of Harvard's genetic engineers. Similar problems are expected in other American cities. Although there is a reasonable chance that such clashes will be avoided in Britain, the longer Mr Mulley delays, the more likely they are to occur.

A second reason for delay may simply be the need for extensive briefing and consultation between departments If so Mr Mulley must lavishly oil the cogs of bureaucracy. Most likely the delay is due to his consideration of the introduction of statutory controls of recombinant DNA research. Although the Working Party is thought to have been reluctant to recommend statutory controls, they may have made some suggestions in that direction because of forceful representation from the unions. The same pressures, which clearly must be respected since the unions represent those most likely to be directly carrying out the research, may now be holding Mr Mulley back.

The British code of practice, with or without statutory backing, could be very influential. In contrast to the American code, which applies only to NIH-supported research, the British code will apply to all academic institutes and probably also to industry via the Health and Safety Executive. If that breadth is matched by an authoritative depth and practical recommendations, the code could well be adopted by other European countries. That could happen through the European Molecular Biology Organisation which meets to consider the matter on August 12. It would be a great pity if the British code had not emerged by then. ☐

Solar energy breeders

Malcolm Slesser and Ian Hounam of the Energy Studies Unit at the University of Strathclyde, Glasgow, offer an opinion on a largely ignored aspect of solar energy

SOLAR energy has not been taken seriously as a solution to our energy supply problem and for good reason. It requires considerable land area and the sun has an unhappy knack of ducking behind clouds or withdrawing into a winter solstice. But there is one aspect of solar energy that is significantly in favour of its large scale development, an aspect which has so far received scant attention. This is the potential for solar energy devices to breed energy. No other device can do that. Yet, given the right technology, we calculate that with an initial investment by 1980 in 1 MW of solar power, it would be possible for solar energy to provide 90% of the world's energy needs within 40 years, without placing any burden upon existing energy resources.

The importance of this claim can hardly be exaggerated. If a solar breeder system was in operation, nearly all the energy from North Sea oil could be devoted to current needs and not, for example, to building alternative energy systems that will be needed when oil runs out. If we have a viable solar breeder system, worldwide, then once that system has grown large enough to satisfy the bulk of world demand the price of energy will fall to a trivial value, because after all the sun is a free good. Such a fact would utterly change the basis of a manufacturing or even a service orientated economy.

What, then, is an energy breeder? It is a device which "breeds" capacity to generate useful energy without consuming energy stocks. In this sense nuclear "breeders" are not breeders but extenders, increasing the potential energy of uranium by roughly 100/0.7, where the 0.7 is the proportion of Uranium 235 occurring in natural uranium. But when a solar capture device (SCD) (or any solar induced device such as a wind or wave generator) delivers in its lifetime more energy than needed to maintain and rebuild itself, then some of that surplus can build more SCDs, thus breeding energy.

Breeding success depends on the pay-back time of the initial energy of manufacture, and energy analysis provides us with a means of assessing it. Through a method known as dynamic net energy analysis, in which energy required to construct and service an energy production or transformation system is set against the system output as a function of time, one can test various breeding scenarios. Unfortunately the energy investment data so far produced on constructing solar energy devices (other than solar heat devices) is unconvincing, and tends to consider only optimal sunlight conditions. Moreover, all too often figures include only direct energy costs, and the more obvious ones like the energy requirements of structural steel and glass No comprehensive results have been published enabling one to estimate the gross energy requirement to build and operate an SCD in an average situation.

Our own tentative energy analysis of 1972 photo-voltaic technology has shown it would take about 40 years output to pay for the energy investment, and since its expected life may be about 30 years it is clearly a sink, not a breeder. However, the new technology of ribbon melting of silicon looked like reducing that to 10 years. In recent discussions with the Office of Technology Assessment in the USA we have learnt of systems which are said to require only a two-year pay-back time. This clearly provides tremendous breeding potential.

If a system could grow while also satisfying its own energy needs—that is to say the energy for construction and operation—it then places no burden on the existing fossil and nuclear energy infrastructure, and the only charge upon the building programme is the labour and management and the land needed for expansion of the system.

Choosing a datum of 1980 for the initiation of the programme of breeding, with an initial 1 MW output capacity SCD system, we examined a range of pay-back times varying from the pessimistic result at Strathclyde (10 years) to the optimistic views of the Office of Technology Assessment (2 years) for various investment policies, to show that energy breeding is a possibility even with as large a value of pay-back time as 10 years, though the rate of breeding is too low to be of real interest. Thus for a policy of 5% investment in new capacity, by 2030 the programme would only have developed an output capacity of 12.2 MW (as against the original 1 MW in 1980) and a net output power would be a mere 4.3 MW—reflecting a system doubling time of about 14.5 years. Yet even that is greater than the global rate of growth in energy demand.

On the other hand, if we accept the optimistic value of pay-back time of 2 years being claimed in some quarters, an SCD breeding programme could be spectacularly successful. For example, with an investment fraction of 40%, an initial output capacity of 1 MW in 1980 would have grown to an output capacity of 8.8×10^6 MW by 2020, giving a net power output to the non-solar energy sector of the economy of 1.7×10^6 MW. By this time the doubling time of the SCD system is only 3.2 years, a rate of growth of energy supply higher than the most horrific energy demand scenarios.

Of course by no means all problems are solved. Though the programme provides its own energy requirements, there are still the problems of land availability and manpower. Some will point out that there is also a need for steel, glass and so on. But of course, the energy analysis has taken that into account through the energy required for construction. Nevertheless, there remains the task of assessing whether the necessary industrial infrastructure to sustain the solar programme can be created, a question we do not attempt to answer here. We merely set out to show that, given the appropriate technology (low pay-back time), a solar capture system could breed itself, and hence in time solve the global energy supply problem. The devices with larger than two-year pay-back times are less satisfactory. Clearly, then, in view of the tremendous opportunities presented by a device with a two-year pay-back time, a massive research programme is justified.

The SCD system output capacity could match even the most ambitious forecasts of demand (4.5×10^6 MW) within 40 years of initiation. From an initial recycle fraction of 80% to new investment, the construction programme falls away to 7% in the 40th year. In net energy terms this is a lower figure than found in our present fossil and nuclear fuel industries. It would be consistent with a price, in current terms, of around £100 per kW for photo-voltaic collectors.

It is interesting to consider what happens to the cost of conventional fossil and nuclear fuels if such a programme took place. By the year 40 (2020), solar energy could so nearly supply all energy needs that oil, gas, coal and nuclear sources will have lost much of the scarcity value they now enjoy. True, oil and gas will remain valuable for their feedstock potential, but nuclear reactors could be rendered redundant and coal mining unnecessary, save as a source of carbon. In such a situation presumably the price of energy falls to a trivial value.

This is offset by the land requirement of SCDs. Taking the 40 year level of output of 4.2×10^6 MW, and assuming that the two-year pay-back time has been achieved, with collection of 20% efficiency, a huge land area is required, around 30,000 km^2 (equivalent to about 12% of the British Isles), but it is spread world wide. However, if the same period of two-year pay-back time applies to solar generated SCDs such as wave and wind power generation, then land requirement falls considerably.

In order to effect the programme, a cumulative energy investment of 1.7×10^6 MW years of energy would have been used—that is about 25×10^9 tons coal equivalent. This is a huge quantity of energy, and reflects a huge amount of material and man power. None of that energy, however, would have come from global energy resources, but from within the programme. Secondly, the basic problem facing all industrialised societies is the need to build a new energy infrastructure within the next 30–50 years. When we examined the task of doing this for the UK imagining an eventual replacement of fossil energy by nuclear and some solar, we found that the massive energy investment called for placed restrictions of UK export of North Sea oil, and a serious limitation on UK economic growth, for the energy investment had to come from existing energy resources and transformation devices. The SCD breeding system, however, permits a parallel economic development without this strain being placed on existing energy resources.

In reality an SCD breeding programme would differ considerably from the simple model presented here. For one thing much of this growth would be dispersed—some citizens for example, building wind generators in their back yards. Technology would change rapidly, and pay-back times would vary according to the sophistication and purpose and location of the device. Much solar energy could be turned directly to heat, through collectors. It is still too early to find whether the torrid dunes of the Sahara will pay a more or less important role than the ceaseless waves of the North Atlantic and South Pacific. But given a short pay-back time and an integrated breeding and development programme, prospects for a low cost energy, nuclear-free world do look good. □

SCIENCE COLLEGE

Modelling the world, again

David Spurgeon in Ottawa looks at two recently published studies of the world's future

WHEN it was published in 1972, *The Limits to Growth* was a kind of landmark, crystallising in a mathematical model the views of those who believed that the world had come to a turning-point in its profligate use of resources, its growing pollution of the environment, and its inexorable population growth. Its message was basically a simple one: that if current trends continued, disaster was certain, because resources which were finite would soon be exhausted, pollution which was increasing would soon become intolerable, and the press of population which was exponential would soon outrun living space.

For many the book was authoritative because it was backed by computer studies—and perhaps because it reinforced existing fears or prejudices. But given its assumptions, its conclusions seemed rather obvious, and it provoked a rash of criticisms, as well as a number of similar studies. Whatever else may be said of it, though, it succeeded in raising the public's consciousness of some of mankind's major problems and prospects.

Two recently published studies* deal directly with the kinds of problem examined by *The Limits to Growth*: one, *Catastrophe or New Society?*, arose as a specific response to it, while the other, *The Next 200 Years*, could be said to have been undertaken in response to its underlying philosophy. Both disagree totally with the assumptions and conclusions of *The Limits to Growth*, while at the same time proceed from assumptions totally at odds with each other. What they have in common is a basic conclusion that the limits to growth—if any—are not physical, as suggested in *The Limits to Growth*, but sociopolitical, and that mankind is not doomed either to a no-growth economy or to disaster but is capable of providing a worthwhile and satisfying future for all. Where they differ is in how such a future could be brought about.

The basic premise of *The Next 200 Years* is that what we need is not less growth, but more—and along pretty much the same lines as at present—at least until world-wide economic development has been completed. After that growth rates will slow and many economies will reach a more or less steady state. *Catastrophe or New Society?*, on the other hand, sees achievement of a good life for all, particularly those in developing countries, as impossible without certain fundamental changes in society. What is wrong with the arguments of Meadows and his ilk, in its view, is that they accept, "in a totally uncritical manner, the central values of society as it now is." Herrera and his colleagues maintain that the major problems facing society

> are based on the uneven distribution of power, both between nations and within nations The result is oppression and alienation, largely founded on exploitation. The deterioration of the physical environment is not an inevitable consequence of human progress, but the result of social organisations based largely on destructive values.

In its place must be constructed a new type of society—socialist, egalitarian, fully participatory, and non-consumerist.

Both books project the future from a very clear ideological base, though the base is made more explicit and acknowledged more directly by Herrera's group than by Kahn's. Both are essentially utopian (Herrera's admittedly so, Kahn's not) and suffer from the basic fault of all such modelling of enormously complex systems. oversimplification, and the necessary exclusion of all sorts of potentially important variables that either cannot be accurately quantified or cannot be foreseen.

Kahn and colleagues argue that "the current malaise", as they call it, is propelled by a combination of compassion and guilt for the plight of the world's poor and the coincidental occurrence of world-wide crises in the supply of food and energy. They believe that the movement toward this view "has gone too far", and argue that there is both need and opportunity for economic growth—that precisely because America and the rest of the developed world use resources so intensely, there will be stimulation, not depression, of the economies of developing nations Using what seems, as far as they reveal it, to be questionable data, the Kahn group suggests current population growth fears may be nothing much more than "an amusing episode in human history". Looking backward from 2176, as they pretend to be able to do, they say "the temporary nature of the current population phenomenon becomes very obvious".

Similarly, energy supplies are no problem. Examining current fossil fuel reserves (on the basis of a 1973 US Geological Survey that has since been withdrawn by that agency and drastically revised downwards) and the prospects for other energy sources, both conventional and non-conventional, developed or not, the authors conclude:

> Except for temporary fluctuations caused by bad luck or poor management, the world need not worry about energy shortages or costs in the future And energy abundance is probably the world's best insurance that the entire human population (even 15–20 billion) can be well cared for, at least physically, during many centuries to come.

The same goes for raw materials ". . . there is an abundance of raw materials for future generations as well as the present one, and . . . the more man develops economically and technologically, the more there will be for all of humanity."

And as for food, "the position we argue is that, except for the occasional regional fluctuations caused by natural disaster, inappropriate policies or the misapplication of resources, the long-term prospect is for adequate food supplies". Within 200 years, the authors say, it will be possible to increase world food consumption to the level of the United States today. What will happen if "inappropriate policies or the misapplication of resources" continues to be the rule, as it is today, is not dealt with. Yet that, as the authors of the Latin American world model recognise, is precisely where the real problem lies.

To give them their due, the Kahn group do recognise this. They go so far as to state that

> any limits to growth are more likely to arise from psychological, cultural or social limits to demand, or from incompetency, bad luck and/or monopolistic practices interfering with supply, rather than from fundamental physical limits on available resources

What seems odd is their faith in things as they are, and their acceptance that they will continue that way.

> . . . Large income gaps between nations could persist for centuries . . . there are few peasants, workers or even businessmen in developing nations who care much about gaps (whether arithmetic or geometric), no matter how much intellectuals, academics and some businessmen may profess to. The major objective of most people is to increase their own safety and improve their own standard of living and their own capabilities. When they make comparisons, it is

***Catastrophe or New Society? A Latin American World Model,* Amilcar O. Herrera, Hugo D. Scolnik, Graciela Chichilnisky, Gilberto C Gallopin, Jorge E. Hardoy, Diana Mosovich, Enrique Otieza, Gilda L. de Romero Brest, Carlos E. Suárez, and Luis Talavera (IDRC-064e; International Development Research Centre, Ottawa, Canada; 1976).

The Next 200 Years: A Scenario for America and the World, Herman Kahn, William Brown, and Leon Martel, with the assistance of the Hudson Institute (William Morrow and Company, Inc., New York; 1976).

> usually with others at their socioeconomic level or with those who have recently been at their own or a lower level.

By such a yardstick, much of the Third World should have nothing to worry about. The Kahn group sees communist Asians with a GNP per capita of about $1,000 by the year 2000, and about half of the Third World with about double that. A desperately poor group, mostly in India but also in parts of Latin America and Africa, could—even with "reasonable" policies—attain only an average of about $200 per capita by the year 2000. But in another hundred years almost all societies should have a GNP per capita of more than $2,000. The fact that others may have 10 to 20 times more is, in their view, of no consequence.

The Latin American world model is based on the premise that, in the new society proposed, the production system has the satisfaction of basic human needs as a main objective. These needs are nutrition, housing, education and health. The mathematical model was constructed around the satisfaction of these needs, differentiated into five sectors: nutrition, education, housing, capital goods, and finally, consumer goods and other services. It was built to test the physical viability of the proposed society. This involved determining the period of time needed and the conditions under which the different regions could satisfy the basic needs to given levels.

The level of food was taken as 3,000 calories and 100 grams of protein per day (3,200 calories in advanced countries); of education, 12 years of basic education between the ages of 7 and 18; and of housing, one house per family. In the developed countries, the minimum dwelling would have an area of 70 square metres for an average family of 3.5 people, costing $4,900 to build. For Africa and Asia, the standard house was more modest because of the current desperate housing situation: 7 square metres per person, at $23.40 per square metre in Africa and $11.20 in Asia. Housing conditions would reach developing country standards in 20 years.

The annual cost of education per student in underdeveloped countries reached a maximum of $150, and an aggregated yield of 4 tonnes per hectare per year was assumed in agriculture. In developed regions, economic growth would be restricted to 1–2% when GNP per capita exceeded $4,500 annually. And for underdeveloped regions, once basic needs were satisfied, growth in GNP per capita had to be at least 2%. This is to gradually reduce the gap between the developed and underdeveloped regions.

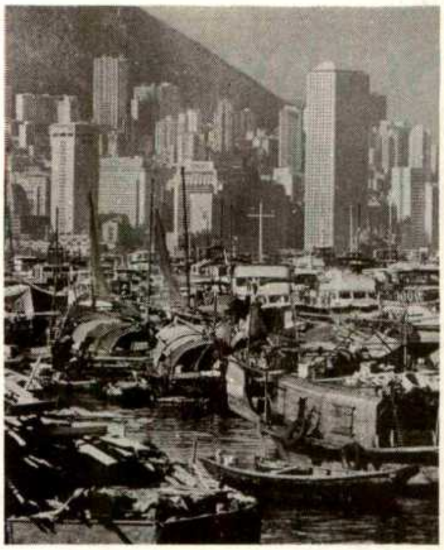
What did the model predict? For developed countries basic needs were shown to be satisfied in the first few years of the computer run (which ended in the year 2060). GNP per capita reached $9,470 in that year (slightly less than Kahn's projection). Latin America could fulfill its basic needs in the early 1990s, and its GNP per capita would rise from $372 in 1960 to $5,746 in 2060. Interestingly, the population growth rate, which was 2.8% in 1960, decreased as general well-being improved, and was only 0.43% by 2060, approaching stabilisation. The consequence for Latin America, then, is that it could satisfy its whole population's basic needs within a generation of the implementation of the proposed policies.

It would take Africa longer: that continent could satisfy its basic needs by 2008. GNP per capita, $137 in 1960, would reach only $559 in 2008, and $2,657 in the last year of the run. Thus if the policies proposed were applied, Africa could satisfy the basic needs of its population with 30 years after 1980, according to the model.

Asia's position is very different. According to the model, basic needs could not be satisfied by 2060. Food consumption of 2800 calories could be achieved by 1992; that level would be maintained until the mid-2020s, but would decline after that until levels reached were incompatible with survival. Nor were housing needs achieved, with only 0.82 house for every family in 2040. Education would be the only basic need totally satisfied by 2040.

"The problem in Asia arises in the food sector," says the report. "By 2010, all available land is being cultivated. Thereafter, economic effort in the sector is devoted to increasing livestock and fisheries. This, however, is not enough to feed the growing population adequately". If agricultural yields were increased from 4 to 6 tonnes per hectare, however, basic needs could be satisfied. GNP per inhabitant—$89.70 in 1960—reaches $1,516 in 2060. But food remains a problem, for in the mid-2030s the remaining land has been used, and "it is inevitable that some years after 2060 Asia will not be able to feed its inhabitants adequately."

Finally, a run was carried out to test the effect of cessation of technological progress in the evolution of the regions involved. It was supposed that there would be no more technological progress after the year 2000. This produced significant effects. In Latin America, it increased the time necessary to satisfy basic needs, increased the population growth rate, and reduced GNP per capita (from $5,746 in 2060 to $1,173). In Africa, as in Asia, minimum objectives could not even be achieved: the economic system collapsed. Only food reached the target level in Africa, and then only for a brief period. In Asia, none of the basic needs were met. Thus technological progress is seen as essential for liberation from underdevelopment and misery.



Two views of the limits to growth?

International aid is not seen by either the Kahn or the Herrera study to be a decisive factor in raising the level of well-being of Third World countries. Under conditions currently prevailing, even increased international aid would only contribute to increased spending by privileged sectors and have little or no effect on the living standards of the majority of the people. In direct contrast to the Kahn hypothesis, Herrera and his colleagues maintain that economic growth without concurrent drastic modification in income distribution would not achieve an adequate level of well-being for the entire populations of developing countries.

Many people tend to argue that studies like these are nothing more than a form of wish fulfillment; that they will increase the skepticism of laymen ignorant of the true nature of future studies and mathematical modelling because they seem to indicate that computer studies can be used to prove any thesis their authors wish; that their obvious political naiveté or ideological bias makes them trivial, if not dangerous. Others will see them as useful contributions to a continuing debate—a debate that must be kept going if solutions are to be found for the problems they deal with. Perhaps they will have done all they can if they succeed in showing, as both studies are intended to do, in the words of the Herrera group, "that the fate of man does not depend, in the last instance, on insurmountable physical barriers but on social and political factors that man must modify." □

BRITAIN

SGHWR: green to amber?

Allan Piper reports on uncertainties surrounding the next generation of British nuclear reactors.

GROWING doubts about the future of the British-designed Steam Generating Heavy Water Reactor (SGHWR) have led the House of Commons Select Committee on Science and Technology to call an inquiry into progress on the reactor system, now at the end of the design stage. The committee two years ago successfully urged the controversial adoption of the SGHWR for the next phase of Britain's nuclear energy programme. It has now expressed concern over "the widely reported intention of the Secretary of State for Energy [Mr Anthony Wedgwood Benn] to review the SGHWR project in the near future".

In fact Mr Benn is currently awaiting reports on technical and economic aspects of the SGHWR from the United Kingdom Atomic Energy Authority (UKAEA), which has recommended a "take-stock" review, and from the Central Electricity Generating Board (CEGB). Parliamentary questions and statements from key leaders of management and unions within the nuclear industry have fed speculation that the reactor may be abandoned as part of the government's present review of public expenditure.

Mr Benn is expected to appear as an early witness in the select committee inquiry, probably before the forthcoming Parliamentary recess. The heads of the nuclear industries and the CEGB will be invited to appear at a later date.

Disagreement over the choice of the SGHWR as the commercial successor to the Advanced Gas Cooled Reactor (AGR) has continued since the initial 4,000 MW ordering programme was announced by Mr Benn's predecessor in July 1974. The go-ahead came then in spite of opposition within the nuclear industry and the CEGB's preference for a much larger programme using mostly American Pressurised Water Reactors (PWRs). The SGHWR was eventually favoured on safety grounds even though estimated construction costs were around 10% higher.

Officially, the SGHWR still has the green light. But there are amber tinges. The PWR has been given a clean bill of health by the Chief Scientist at theDepartment of Energy (DEN), while technical difficulties have pushed design costs of the SGHWR above original expectations. Following a major design review in the middle of 1975, and a further revision earlier this year, the CEGB has calculated that the SGHWR could eventually prove more costly than equivalent coal-fired capacity.

This week Mr Benn spoke in Parliament of the new activity on the American reactor front. Last month he admitted that the UKAEA had recommended a careful look at progress on the SGHWR project, and hinted that once reports have been received the reactor's future will be considered in the light of recent changes on the energy scene. The CEGB, which currently has 15,000 MW of new generating capacity either under construction or ready for commissioning, will probably indicate that with the present slump in electricity demand the first commercial SGHWR planned for Sizewell in Essex is no longer urgently required.

Ditching the project would mean the loss of political face and perhaps more, but it would also avoid economic and technological complications. Development of the SGHWR is not regarded as a crucial step along the path towards fast breeder reactor (FBR) technology, while the export potential of the reactor remains limited; most other countries are expected to opt for the comparatively well proven PWR. Moreover, imported Canadian heavy water, needed to moderate the SGHWR, is likely to prove unexpectedly expensive.

Within the nuclear industry there is feeling that buoyancy can be maintained without the SGHWR if further commercial AGRs can be ordered. The first of the two AGR reactors at the 1,250 MW installation at Hinkley Point in Somerset is now running successfully up to full power, bringing confidence that the much-publicised developmental hitches can now be left behind. Additionally, there are hopes that with a go-ahead for the first commercial FBR this autumn, fast breeder technology could lag only three or four years behind SGHWR technology.

If the SGHWR is abandoned Britain could buy herself into PWR technology and establish an export base under licence. Japan and the USA, and several European countries, however, already have strong footholds in the market, which means that Britain would probably be restricted to the manufacture and export of component hardware. Mr Benn's junior, Alex Eadie, is meanwhile stressing that any reversal of SGHWR policy would not be at the expense of British technology.

Last week the DEN would only reaffirm that Mr Benn was awaiting reports from the UKAEA and CEGB. The UKAEA says simply that it is carrying out an appraisal which will be made available to Mr Benn in the near future. The CEGB is giving no outward sign that any imminent interruption to the SGHWR project is foreseen, and does not expect to have reliable cost figures ready for Mr Benn before next spring. An initial safety report is awaited from the Nuclear Power Company, responsible for design; this is not expected to arrive at the CEGB until next month, and is to be followed in turn by more detailed specifications in April 1977. ☐

CANADA

Towards a conserver society

Like other industrialised countries, Canada must look to conservation as an important element in its future energy stategy. This point has received considerable emphasis from an important quarter, as David Spurgeon reports from Ottawa

ENERGY conservation seems to be the major pre-occupation of the Science Council of Canada in its tenth anniversary year, judging by the statements and publications emanating from its members. The most recent came from the chairman, Josef Kates, who is president of a Toronto firm of systems analysts. "Energy conservation is not an option—it is a necessity," he says in the council's annual report. " . . .The *highest priority* in any comprehensive national energy policy should be *a wide-ranging, imaginative energy conservation effort.* Such an effort must involve every individual and every organisation, private or public."

Dr Kates reinforced his points at a press conference given when the report was published. The reason for his concern is that Canada is the "second most energy intensive country in the world, and energy shortages could threaten the very fabric of our way of life." He says that if Canada's energy requirements also double by 1990, as is currently forecast, the needed capital investment could be as high as $200 billion—or about 5 to 6% of GNP between then and now. This is some 50% higher than the 3.5% average between 1950 and 1975, and the interest rate on this capital is likely to be from 50 to 100% higher than in the 1960s.

This may mean that by the 1990s energy costs will be twice or three times what they are today, and if per capita consumption is also 50 to 100% higher, energy costs could require from two to four times today's proportion of personal income. Canada's historical advantage in such energy-intensive industries as forest products, mining, agriculture, metallurgical and chemical industries could therefore be seriously attenuated. And if primary industries weaken, Canadians could not look to the secondary sector for compensation.

Dr Kates proposes that a much higher priority be given immediately to a comprehensive energy conservation programme, and that Canada must now begin to develop the energy technologies that will permit her to achieve a stable energy use pattern in the long run. This means exploiting renewable energy forms such as solar, wind, geothermal, biomass and tidal power. A major programme of research and development, of the kind first proposed by the Science Council in 1968, must be undertaken "to demonstrate the feasibility of alternative energy technologies."

A recent investigation indicates that "if we were able to hold Canadian energy consumption at present levels and continue to use existing or moderately-expanded hydro-electric capacity to provide approximately 25% of our energy needs, the remaining 75% (now met almost totally by nonrenewable hydrocarbons, oil, gas and coal) could be provided within the next 50 years or so by renewable resources such as solar, biomass and wind energy."

At the press conference Dr Kates described the Conserver Society study the council's largest and most important project. The concepts behind this study, outlined in the "Statement of Concern" published in *Science Forum*, are summed up in the comment that "we face a transition from a 'consumer society' to a 'conserver society' "—that is, to a society which included among its features "doing more with less," "a greater appreciation of external or social costs," a return to the habits of thrift, saving and avoidance of waste for society as a whole, and so on.

"The transition to a Conserver Society," the Science Council paper says, "does not mean that we are going into a period of austerity and shortages. In fact, it is the reverse. Only by adopting a more rational and conserving approach to the common energy, resource, and environmental pool that sustains us all, can we ensure a continuing high standard of living for future generations." ☐

THIRD WORLD

Talking about technology transfer

The transfer of technology from developed to underdeveloped countries, a subject examined at UNCTAD IV at the end of May, was also discussed at the recent World Employment Conference. Robin Sharp reports

SCIENCE and technology, said the man on the rostrum, could increase production everywhere "on a scale that would make poverty unnecessary as a global phenomenon within the foreseeable future." The speaker was a senior official of the United Nations Development Programme, addressing last month's World Employment Conference in Geneva.

But for many people his otherwise heartening words raised questions. How is the scientific know-how and technology of the rich to be adapted and made relevant to the needs of the poor? How are the benefits of these high-cost, skill-intensive fields to be transferred to those possessing limited skills and no hard currency? And how, at the end of the day, can it be ensured that the transfer does not enrich 10 men at the expense of a thousand others? Among the many dilemmas of development these are some of the most intractable, and the debates in Geneva proved it once again.

Some of the figures can be frightening. In the industrialised countries, the average investment required to create one job is in the region of $5,000. The developing countries, with most of the world's poverty, need to create five times as many jobs per million population in order to meet the basic needs of their people, with only one-tenth of the per capita income available to do it. Hence, on a rough rule-of-thumb calculation, an average investment of $250 per job is what they can afford. There is little science and less technology to be had for that kind of money.

On this fundamental issue, delegates to the World Employment Conference found themselves deeply divided. At one end of the spectrum, speakers denounced the appropriate technology movement as a neo-colonialist strategem designed to perpetuate the supremacy of the rich countries. In more measured terms, the French Minister of Labour also questioned the international division of labour proposed to the conference by the International Labour Organisation (ILO), whereby developing countries would specialise in the production of everyday consumer goods, using less sophisticated technology and unskilled labour, while the industrialised countries would concentrate their economies even more in the high-technology sectors.

Put more favourably, however, what the ILO was proposing in its report to the conference was a Basic Needs Strategy in which much greater effort in the field of appropriate technology was seen as essential for maximising the use of labour in the Third World. Given the present level of 300 million unemployed or underemployed in the developing countries, and their estimated need for 1,000 million new jobs over the next 25 years, the ILO strategy is to many the more persuasive formulation. With it has to be swallowed a slower rate of national growth, but in most developing countries the alternative—in terms of human and social cost—would be even less palatable.

Among Third World delegations, the Latin Americans in particular were convinced that they should "continue to incorporate the most advanced technology into those activities where it was necessary in order to eliminate the technological gap." At their preparatory meeting, by contrast, the African group had strongly endorsed the need for more work on appropriate technology as a matter of priority.

In the end, it was the western industrialised countries which blocked the ILO's proposal for two new bodies to promote efforts in this field. A Consultative Group on Appropriate Technology was suggested as a mechanism for mobilising resources and determining research priorities, linked with an International Appropriate Technology Unit designed to identify and focus research in areas where technological innovation would have a significant impact.

Again lacking the support of the employers and western governments, the developing countries and the workers' group declared their support for an international code of conduct on technology transfer, as proposed by UNCTAD a month previously in Nairobi. As well as recommending a timetable for drafting and adoption of this code by the end of next year, the UNCTAD meeting also agreed on the immediate setting-up of regional technological centres under the aegis of either UNCTAD or the UN Industrial

Development Organisation.

Attention was also drawn in Geneva to the damaging restrictive practices contained in a dusty old piece of international law—the Paris Convention of 1883—which defined industrial property rights for a world very different from that of today. With its regulations tivity techniques which would condemn the developing countries to a permaon patents and like matters often working to the detriment of developing countries, they and the workers' group called for this Convention to be "drastically revised."

In its final report, the World Employment Conference endeavoured to strike a balance between the need for technologies which will generate the maximum possible growth of employment and the avoidance of low-producnently inferior role in the world economy. In practice, the technology choices of developing countries tend towards the capital-intensive end of the spectrum where work places will be few and far between for the one thousand million job-hunters in the year 2000. The danger is that what the report calls a "strategy of equilibrium" will be taken by most governments as an endorsement of whatever their policy now happens to be. ☐

USSR

Down Georgia way

Wendy Barnaby, recently in the Georgian SSR, describes some of the scientific work going on there

It takes two and a half hours to fly from Moscow to Tbilisi, the capital of the Georgian Soviet Socialist Republic. In this sunny space between the Black and Caspian Seas, the amount of human effort devoted to science depends on how successfully it—and everything else—competes with the five million Georgians' favourite occupation: the ceremonious consumption of their excellent local wines. And, as a few days spent with the Georgian Academy of Sciences shows, science is coming out of the competition extraordinarily well.

Astrophysical astronomy is concentrated in the southern republics of the Soviet Union, where the weather permits good observation. The air is especially clear on Mt Kanobili (1,700 m), 250 km from Tbilisi and only about 40 km from the Turkish border. Spread throughout the trees on the mountain top is the Academy's Abastumani Observatory, founded in 1937 as the first experimental mountain astro-physical observatory in the USSR. Work here is mainly concerned with galactic research. The resident scientists (including many women) study stars' spectra and classify them in order to examine the distribution of the stars according to their age and chemical composition. From such a distribution investigations are made of the structure of our galaxy. So far, about 100,000 stars have been classified, using a telescope whose diameter is the third largest in the world. During their last 20 years' research, the astronomers have discovered two of the 150 Supernova stars as well as about 100 emission stars.

The observatory's stellar telescope has a diameter of 125 cm and is the biggest fully automatic one in the USSR. The computer attached to it processes 1 million bits of information a second, and its memory stores 32,000 bits. Observations, which can be made on 160–170 nights a year, are mainly for determining the stars' chemical composition, physical properties and light variation. The solar telescope is used more frequently: generally on 260 days a year. Through studying the physical properties of solar flares and sun spots, the astronomers hope to be able to predict solar activity. They also do photometric and spectroscopic studies of optic radiation of the sun's atmosphere, and of radio emission at 220 MHz. The resulting data is shared under the Solar Service Programme.

Back at Tbilisi, the Underground Gravimetric Laboratory of the Academy's Institute of Geophysics is the centre of the Communist countries' cooperative efforts to study earth tides. Half burrowed into a hill overlooking the city, the laboratory is accumulating data which it is hoped will lead to the prediction of earthquakes. In tunnels leading off from basement passages, two double-component quartz extensometers composed of welded quartz tubes have been fixed so that their movements will reflect the tidal and secular deformations of the earth's crust, enabling these to be observed. Any movement is recorded photoelectrically, with a reading of 1 mm on the tape corresponding to a change of 0.1 micron on the ground. Between 1965 and 1972, the value of the recorded drift of one extensometer in the direction N 60°E was 11.9×10^{-6}. The value of deformation in the direction N 30°W between 1966 and 1972 was 14.7×10^{-6}.

Further down the passages, tiltmeters on basalt bases record changes in N–S and E–W directions. The instruments are housed in a chamber 60 m under the ground, where the diurnal temperature variation does not exceed 0.005 °C. From 1967 to 1972, the total drift in the N–S direction was 0.4 microns, and that in the E–W direction was 3.0 microns. The readings from both tiltmeters and extensometers are interpreted by the laboratory's staff as evidence of the existenc of secular movements of the earth's surface. So far there has been no success in using this knowledge to predict earthquakes: neither at this laboratory, nor at a new seismic station nearby, where equipment is being installed for the measurement of seismic waves from local and distant events. (Incidentally, the scientists at the station claimed that their research will enable them to locate and identify nuclear explosions in rock and in the Northern Hemisphere down to less than 10 kilotons. If the station were integrated into an international net, it could presumably contribute to the verification of any future comprehensive test ban treaty).

The Gravimetric Laboratory's methods are also being used to measure the earth's movements at a hydroelectric dam under construction about 50 km from Tbilisi. The plant, which will be completed in 1978, will have a capacity of 130 MW. Its artificial lake will hold 500 million cubic metres which will irrigate 45,000 hectares of land and supply drinking water to Tbilisi and its industrial area for 80–100 years.

Another of the laboratory's activities is the suppression of hail which threatens to destroy large parts of Georgia's grape crops every year. In 1974, 20,000 rockets containing silver iodide were launched from 34 automatically-synchronised firing points to save 360,000 hectares. Radar was used to detect clouds up to 15,000 metres, and results were good if the approaching front was narrow but not so good if it was broad. Because silver iodide is very toxic and expensive, research is being done into substitutes—ice with chemicals, for example.

In addition to coping with a heavy load of scientific work, a number of Academicians—including the Vice-President—represent Georgia in the Supreme Soviet of the USSR. This involves them in political activity to a degree extremely rare for active scientists in the West. Such involvement undoubtedly has its good and bad sides, but inasmuch as it contributes to the activism of science it seems a pity that Western scientists do not become more politically involved in their own societies. ☐

USSR

- The State Committee of Supply (Gossnab) of the Soviet Union is holding up scientific progress, a recent *Pravda* editorial has implied. Soviet policy is, of course, committed to the idea of the scientific and technical revolution as the panacea for social and economic ills, but according to *Pravda* Gossnab persists in supplying research institutes and experimental enterprises as if they were ordinary industrial concerns.

This criticism, from the official organ of the Party, reinforces the picture presented by individual scientists of a vast bureaucracy of order-forms, in which it is virtually impossible, once a project has started, to acquire some auxiliary equipment or reagents not envisaged in the original plan. The vivid description by such unofficial sources is of a standard procedure which includes over-ordering what is definitely needed and arranging to exchange surpluses with another laboratory to provide for unforeseen requirements. The success of a laboratory, it has even been claimed, depends not so much on the abilities of its top scientists, but on the wiliness of its "Fixer" in arranging such unofficial supplies.

Although *Pravda* makes no overt reference to this self-help system, this is clearly what lies behind the statement that "in the opinion of many scientists and specialists, what is needed is a system for the immediate supply of everything found to be necessary during the course of experiments and the development of experimental models." This "would permit the acceleration of scientific progress", presumably by making allowances for serendipity and eliminating the need for a marked degree of prescience. Gossnab, however, "is delaying with the creation of such a system".

The tendency to treat science as simply another branch of production is not, however, confined to Gossnab. The implementation of basic research in industry is one of the major themes of Soviet planning; considerable funds have accordingly been allocated to this end and a large number of research bases have been set up. Not all these facilities, however, are being used for their proper purpose. Thus, the Ministry of Gas Production has an excellent research establishment at Donetsk, but instead of using it for testing experimental models of new equipment, a large proportion of it has been handed over to routine production, while only a small fraction is used for the prime purpose of research and development. Examples of proper cooperation in this field, such as that developed by the Byelorussian Academy of Sciences and its subsidiary institutes on the one hand, and the industrial enterprises of the Byelorussian Republic on the other, to form what *Pravda* describes as "a truly powerful experimental base of science", are still, it would seem, sufficiently rare to evoke glowing press reports when they occur.

Another major problem facing Soviet research is the lack of sufficient scientific instruments. Here the problem is one of demand exceeding supply, so that in spite of considerable efforts by the relevant Ministries (Instrumentation, Automation and so on) and scientific bodies from the Academy of Sciences downwards, there are still considerable shortages. One recent development has been the establishment of rental centres, from which expensive and complex equipment may be borrowed for specific experimental projects. Such centres are already in operation in Moscow and Leningrad, and the Rental Department of the Siberian Metrology Institute, now in its fourth year of operation, supplies "hundreds of scientific and industrial organisations" of the developing regions of Siberia. The collective use of equipment, whether via rental centres or "on the principle of the comradely mutual aid and cooperation of Institutes" is especially recommended. The use of computers in planning scientific supply is urged, but with the cautious proviso that computers are to be employed thriftily.

For several years now, centralised and computerised planning has been a major aim of the logistics of Soviet science. This new emphasis on economy of computer use, and the suggestion that individual institutes might profitably make mutual equipment-sharing arrangements with other institutes, is a far cry from legalising the present system of unofficial exchanges of specially stockpiled surpluses. It does, however, indicate a growing recognition on the part of the authorities that running research and development on the same state-wide standardised pattern used for the production industries is at least problematical.

- The Soviet space programme, being based on Tsiolkovskii's concept of long-term orbital space stations as a prerequisite of any manned missions to the moon or planets, has always been greatly concerned with the medical problem of prolonged weightlessness. The death of the Soyuz 11 team upon re-entry, although finally proved to be due to a faulty hatch-seal, at first evoked considerable fears that the tragedy was due to some unsuspected side-effect of prolonged weightlessness. Accordingly, in addition to the usual programmes of astrophysical observations and the checking of equipment, the current Soyuz 21/Salyut 5 mission is paying special attention to the effects of weightlessness.

As usual, medical data—cardiovascular and respiratory action—is being telemetered to ground control; in addition, however, the cosmonauts have on board what the TASS agency describes as a special set of scales to enable loss of body mass to be monitored. What precise form these scales take, and how they can operate in conditions of zero gravity, is not specified. A similar question is posed by another on-board experiment—the presence of a tank of guppy fish which will be periodically filmed to record their adaptation (if any) to weightlessness—since submersion in water is a standard procedure for simulating weightlessness in pre-flight training missions.

Whatever the precise significance of these experiments, however, it seems clear that Soviet plans are moving towards longer and longer missions. Increasing attention is being paid to both physical and psychological well-being—an endless-belt "running track" and a colour-slide projector for light entertainment are carried on the latest mission. A new central control panel aboard Salyut 5 gives greater facility for the cosmonauts to operate scientific equipment during experiments, reducing their dependence on ground control and preparing the way for fully autonomous space missions whether in orbit or beyond.

Vera Rich

IN BRIEF

ESA scientific programme

The European Space Agency is in the process of selecting its future scientific satellite and shuttle payloads. Studies of 16 possible projects were presented to European scientists at the end of last month in Paris. The astronomy and solar system working groups subsequently made recommendations and the Science Advisory Committee then listed the next scientific projects to be undertaken: cooperation on the space telescope with NASA, an out-of-ecliptic and solar stereoscopy mission and a large infrared telescope on Spacelab. Final decisions will be taken in September, but UK scientists are meeting this week to identify their main areas of interest. They may also voice their objections about where the axe has fallen among the original projects.

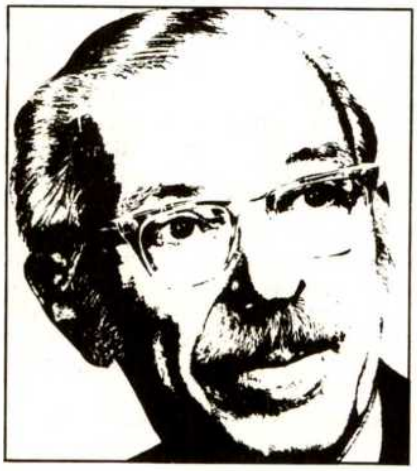
Reprocessing debate continnes

The social, technological and environmental problems associated with the management of radioactive nuclear waste came under the spotlight last week during an international meeting of nuclear power experts in Denver, Colorado. Sir John Hill, Chairman of the UKAEA, pointing to national and international regulatory agencies, warned against premature adoption of inadequate short term safeguards on the one hand, and unnecessary delays to nuclear expansion pending the development of a "final [reprocessing] solution" on the other. Sir John foresaw no imminent changes in UK waste management policy, so that work on vitrification processes would continue, which need not ultimately preclude incineration. Even with widespread nuclear development, he said, radioactive waste arisings would be small compared with world mercury and arsenic stocks.

Meanwhile, amid reports that western Europe will have only about half of the reprocessing capacity it needs by 1980, work has begun on the site for British Nuclear Fuels Ltd's (BNFL) new reprocessing facility at Windscale. With construction costs estimated at £350 millions (the UK Government has just underwritten BNFL borrowing of £75 millions) the installation is expected to handle 1,000 tonnes of spent fuel a year by the mid-1980s.

A call for an outright ban on the sale of the technology for reprocessing will, however, be made at the annual conference of the British Labour Party in September. A motion urges the UK Government to consult with the group of nuclear exporting countries on the matter.

Mad about safrole



THOMAS H. JUKES

THE name of sassafras tea conjures up thoughts of early days in North America, of folk medicine, and of a tree whose leaves, charmingly enough, grow in three different shapes on the same branch—some are three-fingered, some are mitten-shaped, and some are just oval. The name is Spanish, but the Onondaga tribe in New York State called it Wah-eh-nak-kas—"smelling stick".

Pull up a sassafras seedling. You can peel the bark from the root, and sniff at the fragrance of the core. This spicy aroma led to its use as a flavour for root beer, which is a popular soft drink well-known to Americans and Canadians. But, alas, after many generations of people had enjoyed the natural flavour of sassafras, it turned out that safrole, the substance responsible for this, caused cancer in rats. Oil of sassafras, which contains about 80% safrole, was therefore banned as a food additive in 1960.

Manufacturers of flavoring extracts switched to methyl salicylate, present in wintergreen berries, as a substitute for oil of sassafras, and root beer continued to flow wherever soft drinks were sold in North America. The change made for a somewhat linimentous tang in the beverage, but the salicylates have a clean bill of health in the field of cancer. Also, wintergreen grows beneath sassafras trees in the Appalachian woodlands, so that there was an ecological link between the old flavour and the new.

But safrole still lurked in packages of dried sassafras root that are sold in "health food" stores to lovers of herb teas. These infusions are rumoured to be good, in a generalised way, for what ails you. By sipping them, you get all the benefits of hot water plus whatever happens to be in dandelion heads, camomile, dried parsley, peppermint leaves, comfrey, rosemary (that's for remembrance), verbena, yerba maté, and, of course, sassafras.

Since these ingredients contain hundreds of compounds that have never been biologically tested for anything, herb teas are apparently considered harmless, and in addition, their consumption is hallowed by ancient custom. Unhappily for tradition, the Commissioner of Food and Drugs sternly pointed the finger "to make it clear that the prohibition on the use of safrole in food includes safrole-containing sassafras sold to make sassafras tea; effective June 10, 1976."

Comments had come from private citizens and people in the herb tea business. Several felt it was unlikely that sassafras tea is injurious to health even if safrole is carcinogenic, in one case because the tea is consumed in the spring, and in another because it had "been used for centuries without reports of carcinogenic or other toxic effects." Others noted that safrole was present in other foods such as nutmeg and mace and that hence the ban should include "all food substances containing detectable amounts of safrole."

This, of course, would be in accordance with the rules laid down by the "Delaney Amendment" in the Food Additives Law. The Commissioner replied, in effect, that he couldn't ban everything, and he had to take care of the most concentrated source of safrole first. One correspondent stated that the fat of charcoal-broiled steak contains carcinogens and that "action on sassafras should be deferred until something is done about that." No one mentioned cigarettes.

Several comments expressed various forms of anguish that a natural food, or food constituent, or ingredient, or component should be regulated, saying that this treatment should be reserved for chemical additives. Gently, the Commissioner reminded them that all food ingredients, including natural food constituents, are chemicals, also that the definition of "food" includes food additives.

The ban showed that sauce for the Red Dye No. 2 goose is also sauce for the sassafras tea gander.

Plea for Argentinians

SIR,—We are writing to call the attention of your readers to the harassment many of our colleagues in Argentina are undergoing at the present time.

The Junta Miltar headed by the general Jorge Videla has recently passed a law (ley de prescindibilidad, n.21.274) which allows to "release from duty" any employee of the public administration for unspecified "reasons of service", without further justification. This law has been the ground for expelling political dissenters from the universities and other scientific institutions, mainly in Buenos Aires and La Plata. The most affected institutions are, so far, the CONICET (Consejo Nacional de Investigaciones Cientificas y Technicas), the institutes depending on the Comision Nacional de Estudios Geoheliofisicos, and the Institudo Nacional de Tecnologia Agropecuaria. Not less than 550 persons have lost their jobs: biologists, physicists, chemists, medical doctors, architects, technicians and officers, some of them after 20 years, or more, of service.

On May 7 the newspaper *La Opinion* reported that the Representative on the Junta Militar in the Ministry of Education acting as State Secretary for Science and Technology had decided to "release" 90 employees. The newspaper quoted a few names of distinguished scientists. On May 12, in *La Opinion*, Horacio Encabo (vice-Director of the Centro de Investigaciones Neurologicas Torcuato Di Tella) expressed his worries in an article emphasising the risks for the development of Argentina of a scientific policy inspired by the criterion: "quien no es occidental y cristiano es subversivo" (who is not occidental and christian is subversive). Encabo was "released from duty" five days later.

Besides protesting against these vexations there are other ways of supporting this courageous political and moral stand of our colleagues: anyone can join us by writing to those he or she may know personally or by name: informing them of his or her work by sending reprints of preprints or reports in fields of common interest: doing anything else to let them know that they are not left alone or forgotten by the world community of scientists to which they belong.

Yours faithfully,

Nuclear trade

SIR,—As one who objects to all nuclear explosions, I would like to comment on "Heavy Water Allegations" (June 17, page 537). While I can understand Senator Ribicoff's concern about India misusing US-supplied heavy water, I personally feel that most of those who object to India's nuclear tests are hypocritical. How else does one explain the deafening silence that greeted the revelation that Israel had at least twenty bombs in the 20–30 kiloton range? The critics of India's nuclear tests might well support Israel, using the well-worn argument that Israel is a perennially threatened state But does any state's territorial integrity warrant a nuclear holocaust? I do not know if the US has aided Israel's nuclear programme, but I think it is reasonable to suppose that it did. If so, why does not Senator Ribicoff condemn Israeli nuclear tests?

The only way to save the world from nuclear destruction is to ensure that no country has a nuclear bomb. The present NPT cannot achieve this end because it is iniquitous. It assumes that the top five nuclear powers are the only ones which can be expected to behave responsibly. No self-respecting nation can tolerate this super-power arrogance. Those that have signed the NPT have done so under pressure. What we need today is a total elimination of nuclear arms. If this sounds naive and unattainable then, I assert, we have to be naive and we have to attain the unattainable if we want to prevent a world-wide Hiroshima.

The cynicism which characterises all super-power pronouncements on nuclear arms must give way to an enlightened idealism. The USA and the USSR should really be talking of Strategic Arms Elimination and not of Limitation. The West has provided enlightened leadership on several issues. Is it too much to expect it to collectively lead the world back to peace and sanity? You have produced both Bertrand Russell and Ronald Reagan. Is it unrealistic to expect that you would follow the former and not the latter?

Yours faithfully,

Genetic engineering

SIR,—If, as Mr Norman reports, (July 1, page 2), the NIH did indeed recommend that, for safer recombination experiments, the recombinant DNA have "less than 1 in 10^{-8} chances of surviving in the natural environment", then the critics of such experiments should have even more qualms one in 10^{-8} is equivalent to 100,000,000 to 1.

Yours faithfully,

JEROME G BUESCHER

Department of Microbiology,
Thomas Jefferson University,
Philadelphia, Pa.

Human anatomy

SIR,—We were interested to see Anthony Harris's measurements of asymmetry in young women (May 6, page 10) and the response of Connolly and Dangerfield (May 20, page 188), and have found our ratios right to left of ankle 1.006, calf 1 02, biceps 1.04, wrist 1.02.

We conclude, assuming we are average females, that Anthony Harris's conclusions are correct and asymmetry is commonplace

Yours faithfully,

Are earthquakes a major cause of the Chandler wobble?

from Hiroo Kanamori

WHETHER or not earthquakes are a major cause of the Earth's free Eulerian nutation (period of 14 months), widely known as the Chandler wobble, has been a controversial issue. The present consensus seems to be that the crustal deformation associated with earthquakes is much too small to explain the amplitude of the Chandler wobble. O'Connell and Dziewonski (page 259 of this issue of *Nature*), however, suggest that earthquakes represent the major factor in the wobble excitation. Since their analysis is very direct and unambiguous, it is important to examine what makes their conclusion distinct from others'.

At one time, there were significant disagreements between theoretical results concerning the excitation of the Chandler wobble obtained by different investigators. This controversy, however, seems to have been completely settled, and the theory is now formulated in a rigorous framework. Observationally, the overall pattern of polar motion seems to be well established, although the data may not be good enough to allow correlation of the fine structure of the trajectory with individual earthquakes.

The physical size of great earthquakes has only recently been measured very accurately. Traditionally, the earthquake magnitude M_s (often called the Richter scale) is determined at periods of about 20 s, but it does not necessarily represent the total crustal deformation associated with earthquakes. In fact, the M_s scale is saturated at a magnitude of about 8 or when the fault length becomes about 100 km. Any earthquake whose fault length exceeds 100 km has M_s of 8.3 ± 0.3 regardless of whether the fault length is 100 or 1,000 km. This does not mean that other measures of earthquake "size" such as energy or seismic moment are similarly bounded. In order to measure accurately the physical size of great earthquakes, precise measurements of long-period seismic waves are necessary. The amount of the overall crustal deformation is best expressed by the seismic moment M_o which is proportional to the product of the fault area and the average displacement on the fault. With the recent progress in long-period seismology, the seismic moment has been determined for many great earthquakes. The fault geometry of great earthquakes is also important. With the advent of plate tectonics, it is reasonable to assume a fault geometry which is consistent with the contemporary plate motion.

In these circumstances, the paper by O'Connell and Dziewonski represents a very timely contribution. Most discussions in the past have dealt with either statistical correlations or correlations between an individual break in polar motion and a particular earthquake. The statistical arguments are somewhat indirect, and the arguments on individual events are hampered by the poor quality of the data. In order to circumvent these shortcomings, O'Connell and Dziewonski used geometries of great earthquakes predicted by plate tectonics, and computed the cumulative effects of earthquakes on polar motion rather than the effect of individual events.

Since the seismic moment M_o is not known for most old earthquakes, O'Connell and Dziewonski estimated it by using the relation $\log M_o = 8.8 + 2.5\,M_s$ which is obtained from the work of Chinnery and North (*Science*, **190**, 1197–1198; 1975). The M_s scale used in the above formula is based on Gutenberg and Richter (*Seismicity of the Earth*, Princeton University Press, 1954) and is very close to what is called the 20 s surface-wave magnitude. On the other hand, O'Connell and Dziewonski used the magnitude scale adopted in Duda's catalogue (*Tectonophysics*, **2**, 409–452; 1965) to estimate M_o. The magnitude scale used in Duda's catalogue is, however, different from Gutenberg–Richter's M_s; the former is systematically larger than the latter, a fact which is not widely recognised.

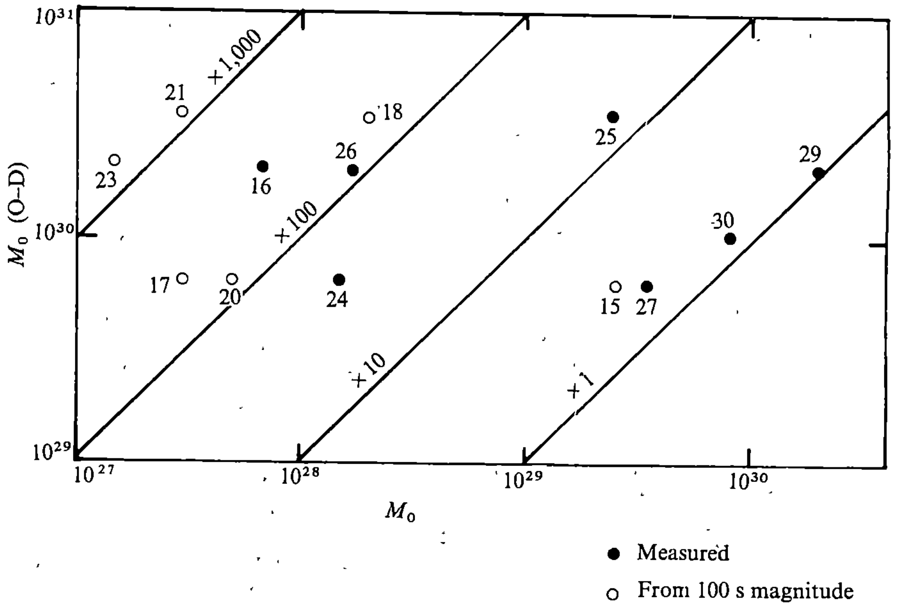

Fig. 1 Measured seismic moment M_o *versus* seismic moment M_o (O-D) assigned by O'Connell and Dziewonski for thirteen earthquakes. Closed circles indicate earthquakes for which M_o is directly determined (from Kanamori and Anderson, *Bull Seismol. Soc Am.*, **65**, 1073–1095; 1975; Ben-Menahem, Aboodi, and Schild, *Phys Earth planet. Int.*, **9**, 265–289; 1974), and open circles are for earthquakes for which M_o is estimated from the 100 s magnitude (Brune, and Engen, *Bull. Seismol. Soc. Am.*, **59**, 923–933; 1969). Numbers refer to those in Table 1 of O'Connell and Dziewonski.

For shallow ($H \leqslant 60$ km) earthquakes for the period from 1905 to 1952 listed in Table 1 by O'Connell and Dziewonski, the average difference between the two scales is 0.3. Thus, the use of Duda's values in the above M_0 *versus* M_s relation results in an over-estimate of M_0 by a factor of 5.6. Since the polar shift is linear with the seismic moment, this difference would mean that the effect on the Chandler wobble computed by O'Connell and Dziewonski is, on the average, 5.6 times too large. However, it is more important to note that because of the saturation of the M_s scale beyond 8, any M_0 *versus* M_s relation is useless for earthquakes of $M_s \geqslant 8$. For these large earthquakes direct determinations of M_0 are essential. Fortunately, for seven earthquakes listed in Table 1 of O'Connell and Dziewonski, a direct determination of M_0 has been made, and for six other earthquakes the 100 s magnitude (from which M_0 can be estimated fairly accurately) has been determined. In Fig. 1, these seismic moments are compared with those estimated by O'Connell and Dziewonski from Duda's catalogue through the M_0 *versus* M_s relation. For earthquakes with very large rupture dimensions such as the Chilean (No. 29), the Alaskan (No. 30) and the Kamchatka (No. 27) earthquakes, the agreement is very good, but for many earthquakes with smaller rupture dimensions, M_0 seems to be overestimated by more than two orders of magnitude. For most events before 1923 no direct determination of M_0 has been made, but it seems almost certain from the above comparison that M_0 is overestimated in a similar manner.

O'Connell and Dziewonski, in fact, considered most of these problems carefully in their article, but in view of the good accuracy of moment determinations even for relatively old earthquakes it appears that the direct effect of earthquakes is about one order of magnitude too small to explain the Chandler wobble. But as they suggest, it is possible that earthquakes accompany very large aseismic deformation which has not been detected by existing seismological instruments. Then the fact that O'Connell and Dziewonski could explain the temporal behaviour of the Chandler wobble amplitude by using the mechanisms of earthquakes derived from plate motion may suggest that accelerated, but aseismic, plate motions are associated with great earthquakes (Anderson, *Science*, **182**, 49–50; 1974). Although such aseismic deformation has been suggested from several independent observations (of tsunami earthquakes, slow pre- and post- seismic deformations, disparity between plate motion and seismic slip rate for example), the details are at present unknown. With world-wide deployment of high-quality ultra-long period instrumentation (see Agnew *et al.*, *EOS*, **57**, 180–188; 1976), it is hoped that the nature of such aseismic deformation will be revealed in the near future. ☐

Long palindromes in eukaryotic DNA

from T. Cavalier-Smith

ONE of the most fascinating differences in the organisation of DNA in eukaryote cells (those with a distinct nucleus) from that in prokaryotes (bacteria and blue-green algae) is the abundant occurrence—in higher eukaryotes at least—of long palindromes. When applied to nucleotide sequences in double-stranded DNA the word 'palindrome' usually means regions of DNA with an axis of two-fold rotational symmetry which would be read the same in both directions by the cell's transcription machinery:

$$\begin{array}{c}\longrightarrow\\ \mathrm{C\ A\ T\ A\ T\ G}\\ \mathrm{G\ T\ A\ T\ A\ C}\\ \longleftarrow\end{array}$$

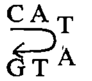
would for example, be transcribed to give an RNA molecule with the sequence $\underrightarrow{\mathrm{C\,A\,U\,A\,U\,G}}$ whichever end the RNA polymerase started, because the polarity of the transcript (shown by the arrow) is always antiparallel to that of the template strand.

(A few authors call sequences like

$$\begin{array}{c}\longleftarrow\\ \mathrm{G\ T\ A\ A\ T\ G}\\ \mathrm{C\ A\ T\ T\ A\ C}\\ \longrightarrow\end{array}$$

"palindromes", but though when no account is taken of polarity each individual strand appears palindromic, the sequence does not show two-fold symmetry, and if it were read in both directions by RNA polymerase two quite different RNA sequences would be made—its biological meaning is quite different when read backwards. Here I use 'palindrome' only for sequences with two-fold symmetry.)

Since palindromes are inverted repeats they can be easily identified because the two strands are self complementary. If denatured to separate the strands and then returned to renaturing conditions each strand will rapidly fold back on itself to form a double-stranded hairpin loop:



These can be separated from non-palindromic DNA because they bind strongly to hydroxylapatite. Wilson and Thomas (*J. molec. Biol.*, **84**, 115; 1974) found numerous almost perfect palindromes in *Drosophila*, *Xenopus* and human DNA. Usually 300–1,200 nucleotide pairs long, they form several percent of the total DNA and like non-inverted medium repetitive sequences, are widely dispersed in the DNA and not clustered in some special fraction. Such long palindromes are absent in prokaryotes and may be of profound significance for the organisation of eukaryote chromosomes. In searching for explanations one must bear in mind that not all eukaryote palindromes are perfect. Many are not or have impaired terminal loops (Schmid *et al.*, *Cell*, **5**, 159; 1975; Perlman *et al.*, *Cell*, **8**, 33; 1976).

Palindromes could have many functions. Short ones can serve as recognition sites on the DNA for proteins which themselves have two-fold rotational symmetry. Such short palindromes do exist in prokaryotes· the recognition sites for the *lac* repressor and several bacterial restriction nucleases are palindromes, but these are too short to be detected by hyroxylapatite which in conditions usually used only binds double strands of over 50 base pairs. Another suggestion is that palindromes form pairs of lateral hairpin loops in the DNA which could be important for recombination or other functions. (Sobell, *Prog. Nucl. Acid Res. molec. Biol.*, **13**, 153; 1973). Such paired loops have not been found in isolated DNA, though they can be generated *in vitro* (Karrer and Gall, *J. molec. Biol.*, **104**, 421; 1976). A looped secondary structure (like that of tRNA on a larger scale) would be expected in RNA transcripts of palindromic DNA and has been found in nuclear RNA, including both heterogeneous nuclear RNA and low molecular weight nuclear RNA, though not in cytoplasmic mRNA; however, the length of these loops (which could have an important role in regulation of transcription or RNA processing or transport) is generally shorter than the palindromes seen in the DNA.

Recent studies in *Xenopus* (Perlman *et al.*, *op cit.*) argue against a specific control function for long palindromes. It appears from renaturation kinetic studies that the unique DNA attached to isolated palindromic DNA can include all unique sequences in the genome, and not just a small specific subfraction as would be expected if the palindromes were always attached to the same adjacent sequences. Perlman *et al.*'s interpretation is that the 100,000 palindromes of *Xenopus* are inserted at different sites in different copies of the genome, and that at any one time one tenth or fewer of the palindromic insertion sites (which must occur at average intervals of 2,500 base pairs or less) are occupied. If correct, this implies a more fluid model for the eukaryote genome than is traditional. One would have to postulate either that palindromes are continually being generated or destroyed or are being swapped from one chromosome site to another, probably even during the lifetime of a single individual. Schmid and Deininger (*Cell*, **6**, 345; 1975) have shown that palindromes are randomly positioned with respect to unique and middle repetitive sequences in human DNA.

In 1974 I suggested a mechanism for the replication of the ends (telomeres) of linear chromosomes which requires terminal palindromes (not necessarily very long ones) and an endonuclease specific for the palindromic sequence (*Nature*, **250**, 467). There are indications that a number of viruses, notably adeno-associated virus (Strauss *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, **73**, 742; 1976) may replicate in this way; moreover, as predicted, the ends of the gene-sized minichromosomes of hypotrich ciliate macronuclei are palindromic and probably generated by palindrome specific endonucleases (Wesley, *Proc. natn. Acad. Sci. U.S.A.*, **72**, 678; 1975). Now Karrer and Gall (*J. molec. Biol.*, **104**, 421; 1976) and Engberg *et al.* (*J. molec. Biol.*, **104**, 455; 1976) have both shown that in *Tetrahymena* macronuclei, where in contrast to hypotrich ciliates the bulk of the DNA is not cleaved into gene-sized pieces, the rDNA exists as numerous small linear DNA molecules each of which is a perfect palindrome over 20,000 nucleotide pairs long. This rDNA is amplified 20 times in total amount relative to the rest of the macronuclear DNA, but each molecule contains only two (inverted) copies of each of the two RNA genes.

If, as Karrer and Gall postulate, these long palindromes also have short identical inverted repeats at each end, they could replicate either according to my model or by way of a circular intermediate. Terminal 'minipalindromes' would make it very easy to explain their formation during amplification by failure of the sequence specific nuclease to nick just one end. The study of this process could have far reaching implications for the understanding of eukaryote chromosome organisation. It is in fact very tempting to suggest that all eukaryote chromosomes, and not merely those of hypotrich ciliates, consist of a linear array of potentially independent replicative units terminated by short palindromic sequences.

To end on an even more speculative note, Sparrow and Naumann (*Science*, **192**, 524; 1976) review evidence that the doubling of whole chromosomes may be a major cause of the evolutionary increase in genome size; they suggest this could occur in linear chromosomes by a slight modification of my palindromic telomere replication mechanism suggested by Bateman (*Nature* **253**, 379; 1975) so as to generate a double length chromosome that would (until the genes inevitably diverged during evolution) be a single palindrome like that of the *Tetrahymena* rDNA giant palindrome only far longer. □

Expression of a eukaryotic gene in *Escherichia coli*

from John Atkins

THE development of the technology of cloning DNA fragments from diverse sources in *E. coli* and potentially other organisms, by linking them to a plasmid or phage replicon has provoked much discussion. The possible expression of eukaryotic DNA to produce functional proteins when cloned in *E. coli* has been a key question. A positive answer would greatly facilitate the isolation of a substantial number of eukaryotic genes by enabling their protein products to be detected by complementation of well-studied prokaryotic mutants. Currently the chromosomal eukaryotic genes, which have been identified on cloned segments, are limited to those whose mRNA copies are a large proportion of the total mRNA, generally of some specialised cell type or after appropriate induction, and so can be isolated in relatively pure form. The ribosomal RNA genes also belong to this category (see *News and Views, Nature*, **259**, 173; 1976). Thus an assay based on complementation of auxotrophs would provide a significant extension of the range of genes which could be identified and so studied. Another main reason for the interest in whether eukaryotic genes can be expressed at the protein level, using the existing vectors, is industrial. Will the vectors which have been developed for *E. coli* hosts enable certain valuable eukaryotic proteins to be produced in organisms such as *E. coli* when grown in fermenters?

A number of different groups have started experiments to answer this question about the expression of eukaryotic genes in *E. coli*, but credit is due to Struhl, Cameron and Davis who describe a careful genetic analysis of the first successful experiments in the current issue of the *Proceedings of the National Academy of Sciences* (**73**, 1471–1475; 1976). As the cloning vector this Stanford-based group used bacteriophage lambda. One of the features of certain λ vectors is that transcription originating at one of the powerful λ promoters (P_L) continues into the heterologous cloned DNA and does not terminate at normal (that is rho) termination sites. The Stanford group did not have to utilise this feature of λ, however, as they found that transcription was initiated within the yeast fragment. Whether transcription originated at a sequence fortuitously recognised by *E coli* RNA polymerase (compare cloned mouse mitochondrial DNA, Chang, Larsman, Clayton and Cohen, *Cell*, **6**, 231; 1975) or at the correct yeast promoter, is unknown.

The two *E. coli* mutants used for the complementation tests were histidine auxotrophs both with non-revertible non-suppressible mutations in the *his*B gene such that imidazole glycerol phosphate (IGP) dehydratase activity was not present, although the other enzyme activity, histidinol phosphatase, coded by the same gene was retained (the complementation patterns in the *his*B gene and relationship to the subunit composition of the two enzyme activities are discussed by Loper *et al.*, *Brookhaven Symp*, **17**, 15; 1964). Struhl *et al.* isolated λ phages carrying yeast DNA which complemented both *his* mutants lacking IGP dehydratase although they did not complement single site mutants lacking histidinol phosphatase. This is reassuring as the yeast genes coding for the two enzyme activities are widely separated on the yeast genome. Davis and coworkers next made ^{32}P-labelled complementary RNA *in vitro* using *E. coli* RNA polymerase and DNA from the λ carrying the yeast histidine gene as a template. This RNA was then hybridised to separated fragments derived from an independently prepared yeast DNA sample, and the DNA fragment which gave positive hybridisation was the same size as the cloned yeast fragment from which the complementary RNA was synthesised. As the authors point out, this argues against any contaminant phage being responsible for the complementation. Struhl *et al.* have not yet characterised the enzyme produced, nor the DNA fragment in detail, and any real measure of the efficiency of translation also awaits study. This latter aspect is of interest as one of the very few reports from analogous cell-free translation studies gave a low efficiency of translation (Crawford and Gesteland, *J. molec. Biol.*, **74**, 627; 1973) and whether the efficiency is greater *in vivo* (in relation to other *in vivo* translation), or if it is very message dependent, is unknown. Consequently, any generalisations from the present study should await the results of complementation studies done with a considerable number of different auxotrophs.

The presentation at the recent Miles Symposium by J. Carbon and colleagues suggest that such reports will soon be forthcoming. ☐

More rapidly growing manganese

from Peter J. Smith

Two years ago Scott *et al.* (*Geophys. Res. Lett.*, **1**, 355; 1974) reported the discovery of an unusual manganese oxide crust about 5 km from the axis of the mid-Atlantic ridge at 26°N. The sample in question, a 4.2 cm thick deposit of birnessite with a trace of todorokite, had an abnormally low iron concentration (compared with typical ferromanganese nodules and crusts), was depleted in ^{230}Th and ^{231}Pa and contained unexpectedly small amounts of Cu, Ni and Co. Its most startling characteristic, however, was its rapid growth rate. Whereas ferromanganese nodules and crusts grow on the ocean floor at typical rates of 0.1–1.0 cm per million years, the new sample had apparently grown at a rate of 13.0–25.0 cm per million years.

On the basis of all the evidence Scott and his colleagues concluded that their newly-discovered crust was a product of hydrothermal activity along an active ridge crest and had not, as 'normal' ferromanganese crust, precipitated from seawater. At that time the importance of hydrothermal processes at ridges, though not unrecognised (for example, Lister, *Eos*, **55**, 740; 1974 and others had recently drawn attention to it), was not widely appreciated. Today, however, the situation is rather different Hydrothermal activity is increasingly commonly acknowledged to play a major part in heat transfer at oceanic ridges, probably explaining both the great variability of axial heat flow and the low average axial heat flow observed compared with that predicted from cooling lithosphere models. It is probably also closely involved with the formation of metal-rich sediments at ridge crests.

It is in this changing context that Moore and Vogt (*Earth planet. Sci. Lett.*, **29**, 349; 1976) now report the discovery of two more manganese oxide crusts (A and B), similar to that of Scott and his coworkers but from the vicinity of the Galapagos spreading axis. Sample A is a 2–4 cm thick deposit recovered from an almost sediment-free wall of an axial valley of the spreading centre where the basement age estimated from magnetic anomalies is 0.3 Myr. It consists of a grey banded zone comprising mixed todorokite and birnessite covering a darker friable zone of todorokite. Assuming this sample to have remained a chemically closed system, its maximum age obtained from the ^{230}Th/^{234}U ratio is 6,000 years at a depth of 9–13 mm within the crust and 9,000 years at 6–9 mm. On this basis the growth rate for the outer 1 cm was therefore 100–200 cm per million years, or 100–2,000 times greater than the rate for seawater-precipitated deposits.

Compared with typical ocean floor ferromanganese deposits, sample A has very low Fe/Mn and ^{232}Th/^{238}U ratios, a higher manganese concentration and lower transition metal concentrations. These properties, combined with the rapid growth rate, strongly support the idea of formation by ridge hydrothermal activity in an area where the supply of manganese is enhanced. Indeed, circumstances suggest that hydrothermal activity may be more vigorous here than is usual along spreading axes, for the recovery site is close to the position of the proposed Galapagos hot spot. Be that as it may, the chief competing explanation—that the extra manganese is remobilised from a sedimentary source—would seem to be ruled out by the obvious lack of sediment at the recovery site and a direct association of the crust with igneous rocks such as tholeiitic basalts and, unusually, soda rhyolite.

Sample B, a 4–6 cm thick crust recovered further from the ridge axis at a point where the basement age is 2.4 Myr, is more complex, less amenable to study but in some ways more interesting than sample A It has a 4–6 cm core of grey todorokite and birnessite which is chemically similar to sample A and thus believed likewise to be of hydrothermal origin. But, by contrast, the core is covered with a 3 mm thick layer of darker material indistinguishable from seawater-precipitated manganese deposits.

Chemical analysis shows that this sample could not have remained a closed system. No ages can therefore be calculated from the ^{230}Th/^{234}U ratio, although given the basement age the growth rate must have been at least 2.5 cm per million years. Assuming average precipitation growth rates, the 3 mm covering would then have taken about 1 million years to form around the core. The implication is that the core formed hydrothermally whilst the sample was close to the spreading axis, but acquired a seawater-precipitated coating more slowly as it was taken out of the hydrothermal zone by seafloor spreading.

Taken together, these two samples provide further support for the existence of hydrothermal processes at ridge crests. Why such activity should lead to extreme fractionation of iron and manganese, and thus to deposits abnormally rich in manganese, is another question, however. Moore and Vogt support the view that the iron was removed from the hydrothermal solutions before they debouched into the seawater. Bonatti *et al.* (*Econ. Geol.*, **67**, 717; 1972), following Krauskopf, noted, for example, that iron should precipitate from a hydrothermal fluid before manganese as sulphides or oxides, thereby gradually lowering the Fe/Mn ratio in the remaining fluid. Clearly this process could produce a solution depleted in iron so that at debouchment the manganese would be rapidly oxidised and precipitated. But this explanation is almost certainly incomplete— and there are other possibilities. The full details and significance of hydrothermal activity at ridge crests have yet to be worked out.

Borrowed polypeptides in Qβ replicase

from Pamela Hamlyn

THE enzyme which replicates the genetic material of the single-stranded RNA phage $Q\beta$ — $Q\beta$ replicase — has many interesting properties, not least its specificity. The enzyme recognises, and begins initiation, at the oligonucleotide CCCA found at the 3′ end of both the plus and minus strands (it is a two step replication). The first residue to be incorporated is a G; the A is not copied. *In vitro* the enzyme will replicate poly(C) and C-containing copolymers which suggests it is not too choosy, perhaps only requiring some Cs at the 3′ terminus. But it will not replicate the RNA of other similar phages which also end with CCCA. Weissman has proposed—and there is some supporting evidence—that as well as the terminal Cs the enzyme also recognises another region within the RNA molecule and it is the spatial relationship between these regions that acts as a signal for initiation (Weissman *et al.*, *A. Rev Biochem.*, **42**, 303; 1973)

Another notable feature of $Q\beta$ replicase is that three of the four subunits comprising the enzyme are polypeptides 'borrowed' from the host —*E. coli.* One is the ribosomal protein S1 which the host uses for the correct recognition and binding of mRNA. The other two requisitioned polypeptides are also involved in protein synthesis in the host; they are the polypeptide elongation factors (EF) Tu and Ts Their known function in protein synthesis could be very neatly fitted with possible functions in the Qβ replicase. EF-Tu is able to bind GTP which is the only nucleotide with which Qβ replicase can initiate replication. EF-Ts can remove GDP from EF-Tu in a catalytic exchange reaction. In addition, EF-Tu is able to bind aminoacyl-tRNA and, since Qβ RNA and tRNA both have CCA at their 3′ end, the suggestion was readily made that EF-Tu in the replicase was involved in enzyme—template binding.

The method used to test these hypotheses was to alter the EF-Tu and EF-Ts subunits so that they are no longer effective in supporting protein synthesis, and then to reconstitute Qβ replicase with these modified subunits and test for enzymatic activity with synthetic and natural templates. Brown and Blumenthal have performed these experiments with unexpected results. (Brown and Blumenthal, *J. biol Chem.*, **251**, 2749; 1976; and *Proc. natn. Acad. Sci. U.S.A.*, **73**, 1131; 1976). Using chemical modifiers, they have altered the aminoacyl tRNA binding site of the enzyme subunit which is EF-Tu and shown that, although it now no longer supports protein synthesis, Qβ replicase reconstituted with it is active —in fact its specific activity is very similar to the native enzyme. To investigate the GTP binding site on EF-Tu they used kirromycin, an antibiotic that inhibits protein synthesis by altering the GTP binding properties of EF-Tu but has no effect on the aminoacyl-tRNA binding site. Low levels of kirromycin which effectively inhibit protein synthesis do not affect the replicase activity, suggesting that in replicase EF-Tu does not function by binding GTP. Further careful experiments using reconstituted replicase revealed that kirromycin acted on the enzyme by preventing the formation of an EF-Tu·Ts complex. The authors think that it is as a complex that these two subunits function in native replicase. Support for this is provided by the experiments described in their paper in the *Proceedings of the National Academy of Sciences.* EF-Tu and EF-Ts have been chemically 'crosslinked' (joined covalently) and this complex used to reconstitute the enzyme. Although in this state the elongation factors cannot perform their function in protein synthesis, they do not at all inhibit the activity of the reconstituted enzyme.

Since the replicase is not utilising the known abilities of EF-Tu and EF-Ts perhaps they perform other functions in the host, as yet undiscovered by scientists but recognised by Qβ as useful. More likely the authors think, is that the two subunits have some structural role, perhaps holding subunit II, the one coded for by Qβ, in its active configuration. The enzyme has the ability to unfold its template RNA as it copies it and to keep the two complementary strands apart. Perhaps EF-Tu·Ts could be involved. □

Zinc in enzymes

from Peter J. Sadler

WHEN cultured in normal conditions, yeast uses a zinc metalloenzyme, alcohol dehydrogenase (YADH), during the final stage of the fermentation process, for the conversion of acetaldehyde to ethanol. The role of zinc in the enzyme is intriguing. If Co^{2+} is added to the culture medium it becomes incorporated into the enzyme, and green (but still active) enzyme crystals instead of colourless (Zn) ones (Curdel and Iwatsubo, *FEBS Lett.*, **1**, 133; 1968) can be isolated. Furthermore, if Zn^{2+} is excluded from the growth medium and Mn^{2+} is added, an active Mn^{2+} enzyme is isolated (Coleman and Weiner, *Biochemistry*, **12**, 3466; 1973).

The natural yeast enzyme has a molecular weight of 140,000 and contains four zinc ions. Their role is thought to be similar to the four zinc ions in the mammalian liver enzyme (molecular weight 80,000) which converts ingested alcohol to acetaldehyde. This enzyme (LADH) has recently been the subject of X-ray crystallographic analyses at 2.4 Å resolution (Eklund *et al.*, *J. molec. Biol.*, **102**, 27; 1976) and detailed metal exchange studies in solution (Stykowski and Vallee, *Proc. natn. Acad. Sci. U.S.A.*, **73**, 344; 1976). A close look at these results reveals the conditions in which metal ions can be swopped and activity retained.

Early attempts to remove zinc from LADH and to reconstitute it with other metal ions met with difficulty. Enzyme activity decreases as zinc is removed, but slow conformational changes occur through oxidation of formerly stable SH groups to S-S bonds (Oppenheimer, Green and McKay, *Archs Biochem. Biophys.*, **119**, 552; 1967).

But successful exchange reactions can be performed under an N_2 atmosphere. The zinc atoms behave in pairs: Zn_2 (Zn_2) representing non-catalytic (catalytic) ions. The pairs exchange at different rates. For example, Zn_2 (Zn_2) dialysed against radioactive $^{65}Zn_2$ (Zn_2) initially becomes $^{65}Zn_2$ (Zn_2) and finally $^{65}Zn_2$ ($^{65}Zn_2$). Similarly, $^{65}Zn_2$ (Zn_2) with Co^{2+} added becomes Co_2 (Zn_2) after 12 h (4 °C, *p*H 5.5), and Co_2 (Co_2) after 120 h. But Co_2 (Zn_2) has an identical activity to Zn_2 (Zn_2), whereas Co_2 (Co_2) is only 64% as active. Hence the term catalytic to describe the second pair of zinc ions.

The crystallographic analysis shows the enzyme to be a dimer of two identical subunits, each having two zinc binding sites and one coenzyme (NAD^+) site. As predicted by earlier spectroscopic studies (Foster, Hill and Williams, *Biochem. Soc. Symp.*, **31**, 187; 1970) on YADH, the zinc coordination sites are (distorted) tetrahedral and include cysteine (sulphur) ligands: four cysteines for the non-catalytic zinc, and two plus one histidine (N) and one water molecule for the catalytic zinc. The latter, which is the faster ion in exchange, is situated at the bottom of a 20 Å pocket, whereas the non-catalytic zinc is in a cleft on the enzyme's surface.

An alternative differentiation of the zinc atoms involves binding 1,10-phenanthroline (OP). OP inhibits reversibly Zn_2 (Zn_2) or Co_2 (Zn_2) by binding at catalytic zinc (H_2O displacement) without removing them. OP irreversibly inhibits Co_2 (Co_2) by removing the catalytic cobalt ions. A difference in behaviour of Co and Zn is notable here.

A near-tetrahedral zinc with a water ligand is now becoming familiar at zinc sites in metalloenzymes: carbonic anhydrase (3 His, H_2O), carboxypeptidase (2 His, Glu, H_2O), thermolysin (2 His, Glu, H_2O). Woolley (*Nature*, **258**, 677; 1975) has recently discussed the enhanced reactivity of such water ligands. This may vary with the fractional change placed on Zn by the other ligands, and may account for the exceptional catalytic efficiency of carbonic anhydrase which has one of the largest known turnover numbers, 600,000 s^{-1}.

The non-catalytic zinc or cobalt ions in LADH may simply have structural roles, but this coordination site is strikingly similar to the iron site in rubredoxin and bacterial ferredoxins, and a sequence spacing of coordinated cysteines, X, $X + 3$ is a regular occurrence. Substitution of the non-catalytic zinc with iron should not only produce an enzyme with interesting properties, but also perhaps with evolutionary significance! □

A hundred years ago

VIOLENT shocks of earthquake were felt again on the 5th inst. at Corinth and the surrounding district. The direction of the motion was east to west. Shortly after noon on Monday an earthquake occurred in Vienna Three violent shocks, lasting two seconds, were felt. A panic ensued. Several houses are damaged, and a portion of the old walls has been split.

Excitation of the Chandler wobble by large earthquakes

Richard J. O'Connell
Department of Geological Sciences, Harvard University, Cambridge, Massachusetts 02138
Adam M. Dziewonski
Applied Seismology Group, Lincoln Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts 02142

Superposition of the polar shifts computed for 234 large earthquakes ($M_s \geq 7.8$) that occurred between the years 1901 and 1970 yields a synthetic curve that closely resembles the observed pattern of variations of the Chandler wobble during the same period. We conclude that earthquakes represent the major factor in the wobble excitation.

SINCE its discovery in 1891, the Eulerian free nutation of the Earth, popularly called the Chandler wobble, has been of considerable interest to astronomers, meteorologists, oceanographers and solid earth geophysicists. Throughout this time the mechanisms exciting the wobble have remained elusive, and although atmospheric motions, core–mantle interactions and earthquakes have all been considered, none of these has been either clearly identified as the principal source of excitation or entirely rejected as a partial contributor.

The period of the wobble depends on the Earth's oblateness and its elastic properties, and the observed period is reasonably well accounted for by current Earth models, with the greatest uncertainty coming from lack of exact knowledge of the effect of the oceans[1]. The observed variation of amplitude of the wobble has not been satisfactorily explained, although several different mechanisms have been proposed. These variations must be caused by damping and the excitation of the wobble. These two mechanisms cannot be studied independently, of course, since the excitation needed to account for the observed wobble depends on the magnitude of damping.

None of the estimates of the frequency or damping of the wobble have explicity considered the mechanisms exciting the wobble, and it is conceivable that particular excitations could introduce considerable bias into estimates of the intrinsic frequency and damping of the wobble. For this reason it is advantageous to calculate the excitation from specific mechanisms to remove any such biases, before interpreting the results in terms of the intrinsic properties of the Earth.

In this study we consider the cumulative effect of major earthquakes that occurred between 1901 and 1970 as a source of excitation of the wobble. Previous investigations of the role of earthquakes in exciting the wobble have yielded no clear conclusions. Although Munk and MacDonald[2], among others, had concluded that displacements associated with earthquakes were too small to excite the wobble, Smylie and Mansinha[3] presented evidence for a correlation between times of occurrence of major earthquakes and changes in the direction of polar motion. This suggested that earthquakes could be responsible for a sizeable fraction of the excitation and revived interest in the subject which has become one of the more controversial topics in the geophysical literature.

Subsequent studies[4,5] concentrated on the correlation between individual earthquakes and short term changes in polar motion. Because of the considerable uncertainty in the exact location of the pole at any time, a definite correlation between polar motion and earthquakes could not be firmly established[6,7]. In addition, Dahlen[8] concluded that earthquakes could not account for the observed amplitude of the wobble; his result was based on the calculated pole shifts for the 1960 Chilean and 1964 Alaskan earthquakes and a Monte Carlo simulation of seismicity averaged over the whole Earth.

Nevertheless, there is still highly suggestive evidence of a correlation between global seismicity and changes in the amplitude of the wobble over the period of the past 70 yr (refs 9–11). This suggests that the cumulative effect of earthquakes may account for the long term variations in the amplitude of the wobble, even though the effect of any individual earthquake is too small to be detected above the noise in the data on polar motion. To investigate this possibility we calculated the polar motion expected from major earthquakes over the past 70 yr and compared it with actual polar motion data over the same period. This requires specification of the time, location and source parameters of the earthquakes, as well as the calculation of the change of the Earth's inertia tensor caused by an earthquake.

The synthetic Chandler wobble

The evaluation of the change in the Earth's inertia tensor involves calculation of the static displacement field resulting from an earthquake. Previous workers have solved this problem directly[8,12–14], but some of the numerical results differed by an order of magnitude. Here we make use of the representation of the static displacement field by a linear superposition of normal modes[15]; only the normal modes of degree 0 and 2 contribute to changes in the moment of inertia. The advantage of this approach is that it has been empirically tested; all the modes that significantly contribute to the change in the inertia tensor have been observed (modes ${}_0S_0$, ${}_0S_2$ and ${}_1S_2$ account for more than 95% of the effect) and their excitation and eigenfrequencies can be explained by realistic models of the Earth's structure and the seismic source mechanism. In addition, this independent calculation resolves the differences among the numerical results obtained by other workers.

The change in the inertia tensor C_{ij} caused by an earthquake with an equivalent source moment tensor M_{kl} can be written

$$\Delta C_{ij} = D_{ijkl} M_{kl}$$

where D_{ijkl} is a fourth rank tensor whose components depend on 6 canonical functions of the model of the Earth evaluated at the source depth, and the latitude and longitude of the epicentre. The components of D_{ijkl} and canonical functions for both a uniform Earth model and a realistic Earth model PEM-C (ref. 16) are given in Dziewonski and O'Connell[17]. The expression of the inertia change in terms of the complete moment tensor M_{kl} permits consideration of source mechanisms more general than a double couple[18,19].

The changes of the inertia tensor caused by the 1960 Chilean and 1964 Alaskan earthquakes calculated using the normal mode approach agree well with those calculated by Dahlen[8], so long as similar Earth models are used. Substantial differences can result from using Earth models that differ at the source depth, and a uniform Earth model gives noticeably different results from a realistic Earth model[17].

To specify the source moment tensor for an earthquake one needs to know the orientation of the fault plane and direction of the slip vector (for lack of better evidence, at this time, we shall use the traditional double couple model) as well as the scalar seismic moment. Most large earthquakes occur at plate boundaries and the source mechanisms that have been determined for several earthquakes are remarkably consistent with current plate tectonic models; for example refs 20–23. This suggests that one may reliably estimate the source parameters of large earthquakes on plate boundaries from knowledge of the type of a plate boundary and relative motion between the plates.

The earthquakes with magnitudes $M_s \geq 7.8$ used to calculate the excitation of the Chandler wobble are taken from the catalogue compiled by Duda[24], primarily based on the study of Gutenberg and Richter[25], and supplemented by information from the *Bulletin of the Seismological Society of America* for the years 1965–1970. Since it is the seismic moment M_0 that determines the static displacement, we have used an approximate empirical relation to determine the moments from the reported magnitudes. Figure 1, after Chinnery and North[26], shows the relation between M_0 and M_s for a number of earthquakes for which both have been independently determined.

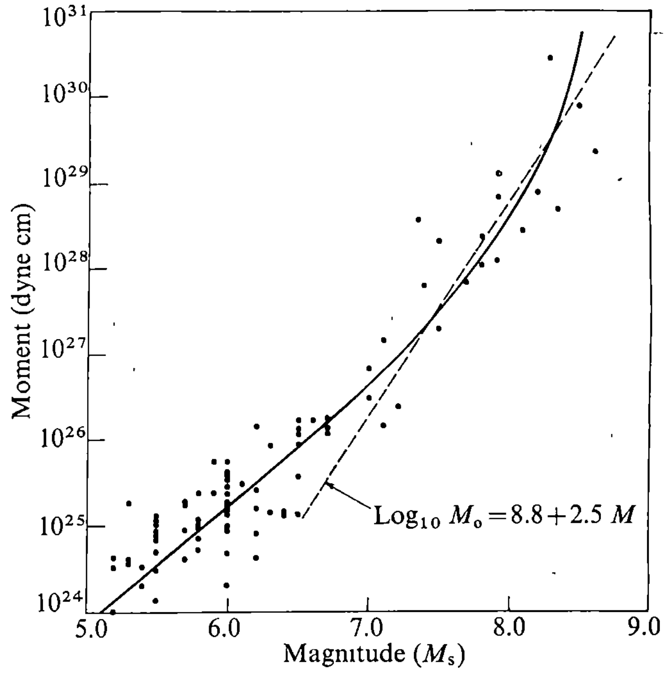

Fig. 1 Relation between seismic moment M_0 and magnitude M_s after Chinnery and North [26]. The dashed line gives the relation used to calculate the pole shifts from earthquakes.

The solid line is the relation between moment and magnitude proposed by Chinnery and North. The dashed line shows the relation we have used to determine the moments; it obviously is a reasonable approximation to the data for magnitudes greater than 7.5.

The paucity of data for the largest magnitudes makes it difficult to assess the reliability of the relation we use, which gives moments of 2×10^{28} dyne cm for $M_s = 7.8$ to $M_0 =$

Table 1 Times and locations of the thirty largest earthquakes contributing to the excitation of the Chandler wobble. The magnitude and direction of the pole shift as well as the change in length of day from each earthquake is shown. Depths designated s were assigned a standard value of 33 km. Earth model PEM-A (ref. 16) was used to calculate the pole shifts*

No.	Year	Month	Day	Lat.	Long.	Depth (km)	Mag	Shift (0.01″)	Dir (°E)	Change in length of day (μs)

*The indicated pole shifts correspond to a change of the position of the principal axis of the moment of inertia about which the instantaneous rotation axis moves in a circular arc with a 14-month period.

3.5×10^{30} dyne cm for $M_s = 8.7$. Nevertheless, these values are grossly consistent with the data, and are all less than the largest moment measured, which was $\sim6\times10^{30}$ for the 1960 Chilean earthquake[23]. Furthermore, the slope of 2.5 in our equation is consistent with the value of 3 proposed by Kanamori and Anderson[27] for large earthquakes.

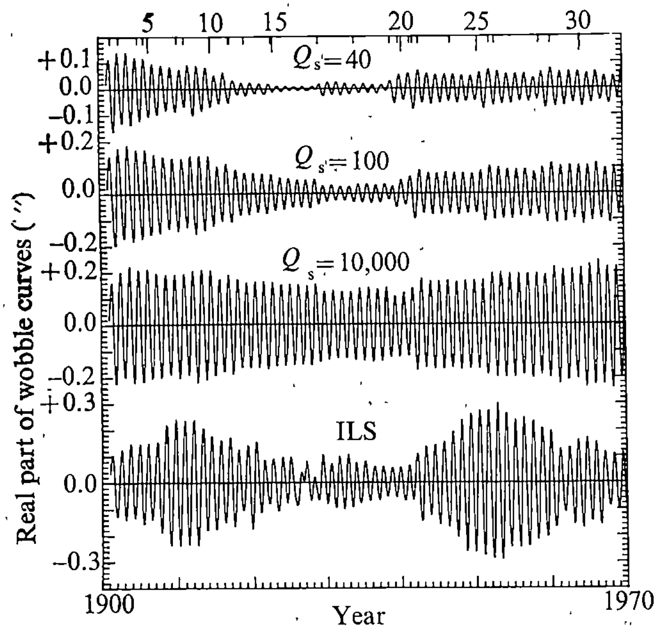

Fig. 2 Simulated polar motion curves resulting from excitation by large earthquakes; the damping for each is determined by Q_s. ILS is smoothed observed polar motion with annual term removed[30]. Only the component along the Greenwich meridian is shown.

The remaining source parameters were determined from plate tectonic models. Using the data of Solomon *et al.*[28] for the positions of the boundaries and relative motions of the plates, we assign fault plane parameters to earthquakes of three types: normal faulting at mid-ocean ridges (dip = 45°, perpendicular to the ridge axis), transform faulting on fracture zones (dip = 90°) and thrust faulting at converging plate boundaries (dip = 20°, perpendicular to plate boundary in the direction of the Benioff zone). Such an assignment was straightforward except for large earthquakes in Asia, and those at complex plate boundaries, which were omitted.

The calculated pole shift and direction are given in Table 1 for the 30 largest earthquakes of those considered. Also shown is the change in length of day resulting from the change in the polar moment of inertia of the Earth. For all cases the moments used were derived from the listed magnitudes by use of the relation in Fig. 1. Results for a different magnitude–moment relation can be obtained by appropriate scaling of the magnitude of the pole shift.

Conspicously absent in Table 1 is the great Sanriku earthquake of March 2, 1933. It occurred near the junction of the Philippine, Pacific and Eurasian plates and it was difficult to assign a particular source mechanism to it. Also, Kanamori[29] has shown that it was not typical of the large shallow earthquakes in the subduction zones; its moment[27] is estimated to be as low as 4.3×10^{28}.

From the calculated pole shifts for 234 earthquakes with magnitudes at least 7.8 between 1901 and 1970 we can compute a synthetic polar wobble curve that would result from this source of excitation alone. For this we also require the starting position $m(t_0)$ of the pole in January 1901 and the frequency ω_0 and damping, Q of the Chandler wobble.

The synthetic wobble $m(t)$ is computed from

$$m(t) = m(t_0)\exp[i\omega(t-t_0)] + \\ + \sum_k s_k H(t-t_k)\left\{1-\left(1+\frac{\omega_0}{\Omega}\right)\exp[i\omega(t-t_k)]\right\}$$

where ω is the complex circular frequency of the Chandler wobble: $\omega = \omega_0(1+i/2Q)$, s_k are the complex pole shifts caused by earthquakes at times t_k, Ω is the frequency of the diurnal rotation and H is the unit step function[12]. The complex function $m(t)$ is referred to the coordinate system in which the real axis corresponds to the Greenwich meridian and the imaginary axis points towards 90°E.

Figure 2 shows the real part (m_x) of three such synthetic wobble curves obtained using $\omega_0 = 5.287$ radians yr^{-1} after Wilson[30] and three different values of Q. Shown for comparison is a smoothed version of the ILS polar motion data, with the annual term removed, also from Wilson[30]. The initial pole location is the same for all curves, and each curve has been bandpass filtered from 0.3 to 0.98 cycles yr^{-1} to facilitate comparison. The ticks on the top of the figure mark the times of the earthquakes in Table 1.

The general trend of the amplitude of the wobble can be seen in the ILS data. The observed amplitude was large in 1910, decreased fairly uniformly from 1910 to 1920 and remained small until 1940 when it began to increase again to reach the maximum value by 1954. Since then there has been an irregular decline in amplitude. The synthetic wobble time series, particularly for $Q = 100$, reproduce the principal features of these amplitude changes. The decrease in the synthetic wobble is caused by the cumulative effect of several large earthquakes from 1914 to 1929. This occurs even for the case with $Q = 10,000$ and it is thus apparent that earthquakes can reduce the amplitude of the wobble and a rapid decay of amplitude need not be attributed to intrinsic dissipation. Similarly, the increase in the synthetic wobble amplitude arises from large earthquakes from 1938 through 1950 which gradually re-excite the wobble. We should note that the decline in amplitude observed since

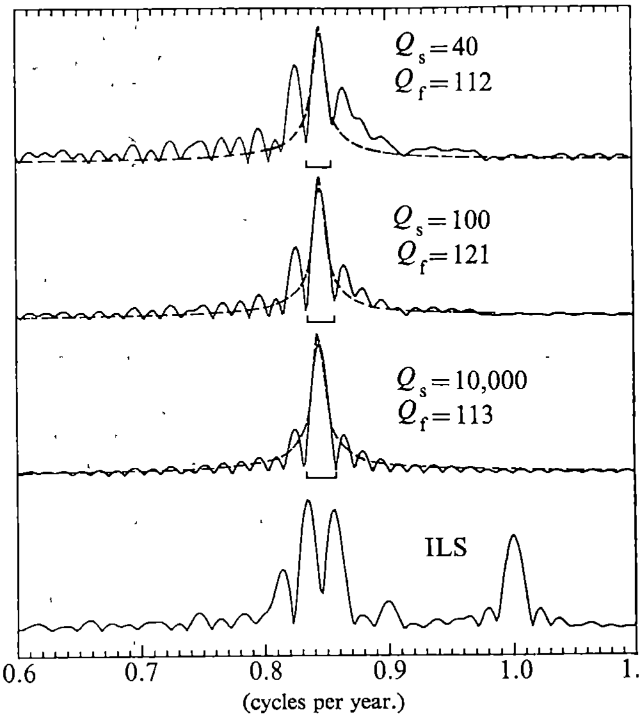

Fig. 3 Power spectra (—) of the simulated and observed (ILS) polar motion shown in Fig. 2. Resonance curves were fitted to the central peaks to determine Q_f (— — — —).

1954 is not reproduced in the synthetic wobble curves; this may be an effect of other sources of excitation or accumulation of the phase shift due to a difference between the actual ω_0 and the value of Wilson[30].

The power spectra of the three synthetic time functions $m(t)$ are compared in Fig. 3 with the power spectra of the ILS data. Although it is clear that we were not able to reproduce exactly the observed spectra, the synthetic curves for $Q_s = 40$ and $Q_s = 100$, each having three well developed maxima, exhibit a similar order of complexity. Also shown is a least squares fit of a resonance curve to the central peak of the synthetic series, which yields an estimate Q_f that is nearly independent of the intrinsic Q_s of the model. This illustrates the fact that a damping of an episodically excited harmonic oscillator cannot be estimated from its spectrum, unless specific assumptions about the nature of the excitation are made[31]. It is clear that reliable estimates of both the frequency and damping of the wobble may depend on the detailed nature of the excitation, especially if it is dominated by a relatively few large impulsive events. Thus an accurate evaluation of the excitation from earthquakes (or other sources) may permit determination of the effective elastic and anelastic properties of the earth at the Chandler wobble period sufficiently precise for comparison with those inferred from seismic observations.

Discussion

The fact that synthetic wobble calculations reproduce the principal variations of amplitude of the observed Chandler wobble substantiates the correlation between global seismicity and changes in the amplitude of the wobble noted by Myerson[9]. Since a given earthquake can either increase or decrease the amplitude of the wobble, the fact that the cumulative effect of several earthquakes is in accord with observations strongly suggests that the correlation is indeed real, and that earthquakes make a noticeable contribution to the excitation of the wobble. Comparison of amplitudes of the synthetic and observed wobble suggests that the earthquake series, with the specific moments assigned through our magnitude–moment relationship could account for $\sim \frac{1}{2}$ of the excitation; the remainder could come from other sources. For example, Wilson[30] has stated that the atmosphere can account for $\sim \frac{1}{2}$ of the observed wobble, and possibly more. If this is true, then the relative contributions to the excitation of the wobble by the atmosphere and earthquakes could be of comparable magnitude.

The magnitude of the seismic excitation exhibited by the synthetic wobble curves depends on the moments assigned to the individual earthquakes. These are quite uncertain, as can be seen by the scatter of points around the lines in Fig. 1. Furthermore, it must be noted that the moments calculated here for some of the earthquakes before 1960 are larger than have been previously reported for the same events (see Table 1 in ref. 27). The moments of earlier earthquakes may have been underestimated because of the lack of adequate long period instrumentation that would allow measurements of amplitudes of surface waves and free oscillations at periods of at least several hundred seconds, so that their wavelengths would be significantly greater than the source dimensions.

While seismic moments are usually estimated from the radiation of the seismic waves associated with the main shock, excitation of the wobble would be affected by the displacements that may take place over a relatively long period of time (several weeks) before and after an event. For example, Kanamori and Cipar[23] identified an 'aseismic' event several minutes before the main Chilean shock (1960); the moment of this event could be equal to, or perhaps even exceed, that of the main shock[32]. Dziewonski and Gilbert[18] reported release of isotropic stress preceding two deep earthquakes; the spectra indicated the aseismic character of these events. Such 'silent earthquakes', whether or not they are followed by major seismic events, may be more common than previously believed. In fact, such a conclusion is suggested by the work of Davies and Brune[33], who compared the cumulative seismic moment release with the average plate tectonic displacement rates at converging plate boundaries. Although they found a good correspondence between cumulative moment release and plate-tectonic slip rates, this only held for shallow earthquakes with an assumed depth of faulting < 60 km. They noted that differential motion at greater depths seems to be accomplished by aseismic deformation. Such deformation may well be associated with large earthquakes and would increase the total shift of the pole over that calculated from the observed amplitudes of seismic waves. In fact the static moments associated with great earthquakes, or aseismic events, are sufficiently uncertain that one cannot rule out the possibility that these account for most of the excitation of the wobble.

This conclusion is not in agreement with that earlier reached by Dahlen[8]. At that time no earthquake had been assigned a moment greater than 10^{30} dyne cm; which led him to restrict the maximum allowed moment to that value. Subsequent redeterminations of the seismic moment of the great Chilean earthquake[23,32] relaxes this restriction and makes plausible the implications of the moment–magnitude relationship used in this report. This, in turn, leads to the calculated excitation comparable to that observed. We note, however, that the 70-yr average of the polar shifts from earthquakes listed in Table 1 is only $0.008'' \text{ yr}^{-1}$; approximately equal to that computed by Dahlen[8] for the 1964 Alaskan earthquake.

The results of this study indicate that the cumulative effects of major earthquakes can account for at least a large part of the excitation of the Chandler wobble, and in particular for the long term variations of the amplitude of the wobble. This, together with recent estimates of the atmospheric excitation of the wobble[30], indicates that these two mechanisms may well account for the entire excitation. If this is verified by more detailed analysis, it should permit more accurate determination of the period and damping of the wobble, and of the effective elastic properties of the Earth at very long periods.

We thank Stephen N. Cohn for his assistance and Don L. Anderson for helpful conversations. This research was supported by the NSF and by the Advanced Research Projects Agency of the Department of Defense.

Possible evidence for penetration of interstellar dust into the Solar System

J. L. Bertaux & J. E. Blamont

CNRS, Service d'Aéronomie, BP No 3-91370 Verrières Le Buisson, France

Because of the motion of the Sun through the surrounding interstellar medium, interstellar dust particles may penetrate deep into the Solar System. In this paper, we investigate the conditions for this penetration and find that the distribution of such particles should peak along the line of gravitational focusing. Two possible consequences are compared with experimental results: the rate at which particles should strike a micrometeoroid detector and the distribution of scattered solar light. We find that the number density of particles penetrating the solar system, derived from this comparison, is much smaller than predicted by a crude model of interstellar matter.

THE velocity of the Solar System relative to local interstellar matter has recently been determined by observation on the interplanetary emissions of hydrogen at 1,216 Å (refs 1 and 2) and of helium at 584 Å (ref. 3). These show that the Solar System is moving through the interstellar gas with a velocity[4] of ~20 km s^{-1} in the direction[3] $\alpha = 252°$, $\delta = -15°$ (equatorial coordinates), different from the apex direction by ~50°, lying in the galactic plane and near (7±3°) the ecliptic plane (Fig. 1).

The measured density of H (0.1 atoms cm^{-3}) and He (0.01 atoms cm^{-3}) and the high temperature of H found by Bertaux *et al.*[4] with the Soviet probe Mars-7 ($(6-13)\times10^3$ K) indicate that the Solar System is not now moving through an interstellar cloud, but through the so-called intercloud medium. These results indicate that the lack of hydrogen found around the Gum Nebula by the Copernicus measurements[5] does not hold for the immediate vicinity of the Solar System.

Matter penetrating into the heliosphere is subjected to two opposing inverse square forces, gravity and radiation pressure. The latter dominates for hydrogen atoms, which are deviated by and from the Sun along divergent hyperbolae, and the former dominates for all heavier atoms including helium atoms: gravitational focusing creates a zone of increased density in the downwind region of the Solar System, along the line $-V_W$ (Fig. 1). Both depletion of hydrogen and enhancement of helium have been observed in the Sun's wake.

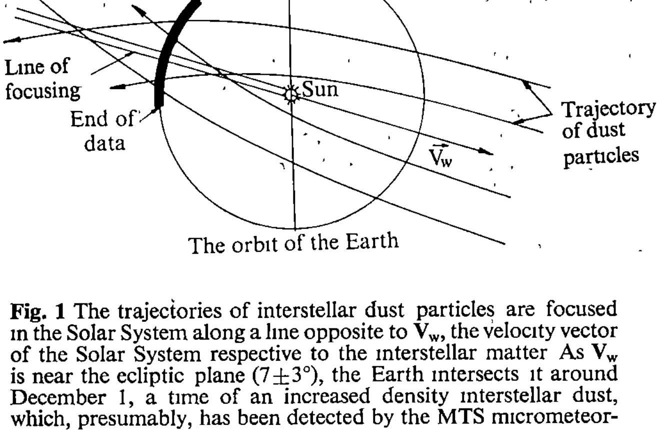

Fig. 1 The trajectories of interstellar dust particles are focused in the Solar System along a line opposite to V_w, the velocity vector of the Solar System respective to the interstellar matter As V_w is near the ecliptic plane (7±3°), the Earth intersects it around December 1, a time of an increased density interstellar dust, which, presumably, has been detected by the MTS micrometeoroids instrument.

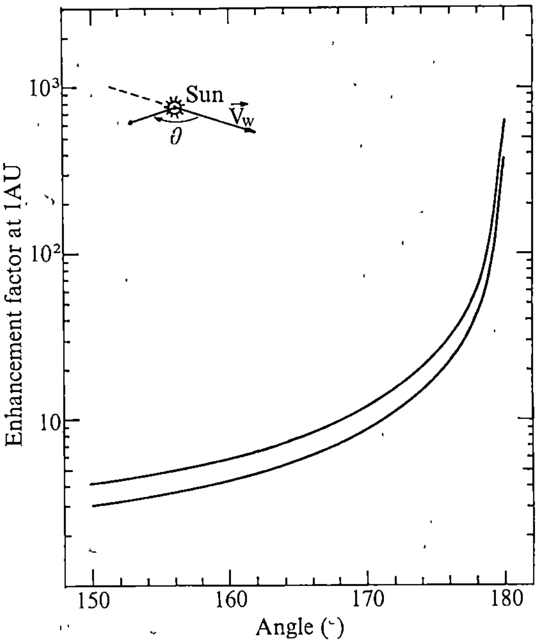

Fig. 2 The enhancement factor of dust particle density in the Solar System caused by gravitational focusing, is computed at 1 AU as a function of angle θ with V_w, for two values of p (the ratio of radiation pressure to gravitation) $p = 0$ (upper curve) and $p = 0.5$ (lower curve).

Since interstellar matter contains dust as well as gas, gravitational focusing will cause an increase in the number density of dust grains along the direction $-V_W$ ($\alpha = 72°, \delta = +15°$). Such an increase should be detectable when the Earth's orbit takes it across this region of space, that is, from November to January.

Distribution of dust grains

We have used a computer program, which we had developed originally to determine the density distribution of interstellar hydrogen and helium in the interplanetary medium, to compute the density distribution of dust grains in the Solar System as a function of the distance to the Sun and the angle θ, measured from the direction V_w of the incident beam (Fig. 2, inset). In this coordinate system, gravitational focusing occurs for $\theta \simeq 180°$. Figure 2 shows the density enhancement factor, E, at 1 AU as a function of θ from 150° to 180°. This factor is defined as the position-dependent number density of particles when solar forces are taken into account, relative to the density of particles in the nearby interstellar medium. The upper curve

Table 1 Parameters of the grains of interstellar dust used in this paper

	Graphite covered with ice	Graphite	Silicate
Relative number	1	10^2	10^3
Radius (μm)	0.5	0.02	0.02
Density of particles (g cm^{-3})	2	2	2.5
Mass of particle (g)	1.04×10^{-12}	6.7×10^{-17}	8.4×10^{-17}
Mass distribution (g cm^{-3})	1.6×10^{-27}	10^{-29}	1.3×10^{-28}
Mass distribution (%)	92	0.6	7
Number density of particles (cm^{-3})	1.5×10^{-15}	1.5×10^{-13}	1.5×10^{-12}
p = radiation pressure/gravity	>1	>1	<1

applies for negligible radiation pressure, the lower for a radiation pressure equal to half the gravitational force. These curves were calculated for dust grains with an isotropic velocity dispersion of 0.1 km s^{-1} added to their bulk velocity of 20 km s^{-1}; a dispersion of 1 km s^{-1} gives almost the same result.

Our model of the interstellar dust

To evaluate quantitatively the possible effects of such a density enhancement, we adopted a crude model of the interstellar dust. The mass ratio of dust to gas was taken as 10^{-2} and the dust was supposed to contain three types of particles: 1 graphite particle covered with ice (radius 0.5 μm) to 10^2 graphite particles (radius 0.02 μm) to 10^3 silicate particles (radius 0.02 μm). The resulting mass and number distribution of these particles in the interstellar medium in the vicinity of the Sun are shown in Table 1. Since the hydrogen number density is 0.1 atoms cm^{-3}, or 1.7×10^{-25} g cm^{-3}, the total dust density is $\simeq 1.7\times10^{-27}$ g cm^{-3} on our model.

The ratio of radiation pressure to gravity—the last figure in Table 1—depends on the size and type of particle and is a crucial parameter in our study. For the first two types of particles, this ratio is greater than one[6]; they do not penetrate deeply inside the Solar System and are not subjected to gravitational focusing. For non-metallic and non-absorbing material, like silicate particles, this ratio is, however, less than one. This is also true for quartz and obsidian particles[7]. Radiation pressure acts as a differentiation process for interstellar matter penetrating the Solar System. Only particles with $p < 1$ will be focused along the downwind axis.

Consequences: (1) micrometeoroids

We invoke this enhancement to explain the observations reported by Alvarez[8] using two micrometeoroid detectors of the MOS capacitor type in terrestrial orbit on board the MTS satellite. The number of impacts as a function of time is shown in Fig. 3. The count rate (slope of the curve) presents a sharp increase (by a factor of 5) around the beginning of November which corresponds to an ecliptic longitude $\lambda = 43°$ for the Earth (Fig. 1). The increase persists up to at least $\lambda = 93°$—just what is expected from the location of the line $-V_W$ (Fig. 1).

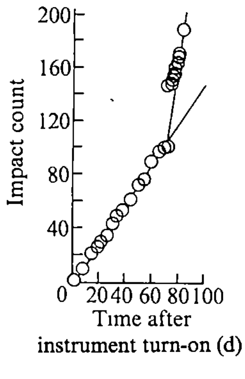

Fig. 3 The cumulative count for impacts detected by the MTS micrometeoroid instrument plotted as a function of time after the second instrument turn-on, which occured 2 yr. after launch. An initial penetration rate of 4.3×10^{-4} m^{-2} s^{-1} (slope of lower line) becomes 2.0×10^{-3} m^{-2} s^{-1}.

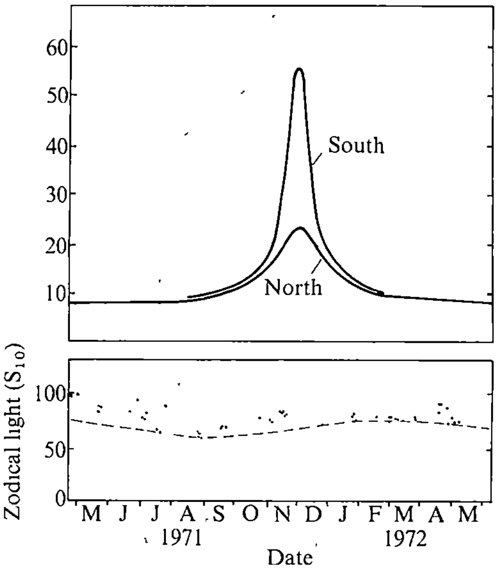

Fig. 4 D2–A observations of zodiacal light in the direction of North ecliptic pole (lower graph) show a bump in November and December, compared with the dashed line showing the expected value. According to the model computation shown in the upper graph, this bump might be produced by the penetration of interstellar dust into the Solar System, concentrated along the line of gravitational focusing, characterised by $n_d\sigma = 2\times10^{-23}$ cm^{-1}.

From the maximum count rate $P_{max} = 2\times10^{-3}$ m^{-2} s^{-1}, and our simple model of gravitational focusing, we may infer the fraction of dust in the near interstellar medium for which $p < 1$. Particles with a velocity V_W of 20 km s^{-1} at infinity have a velocity at 1 AU $V_1 \simeq 46$ km s^{-1} (from conservation of energy). For this velocity one of the two MTS detectors is sensitive to particles with mass $m > 3\times10^{-17}$ g, whereas the other is sensitive to $m > 3\times10^{-16}$ g. The second detector also showed an enhancement at the same time, but somewhat less pronounced. Thus we estimate that the enhancement detected by the MTS instruments comes mainly from particles of interstellar origin with a mass $m \simeq 2\times10^{-16}$ g; this corresponds to a particle radius of ~ 0.03 μm. If n_d is the number of particles in the incident beam (per cm^3) the flux, F, at 1 AU in the region of enhancement is

$$F = n_d E V_1$$

since $E = 10$, $V_1 = 46$ km s^{-1}, $F = 2\times10^{-7}$ cm^{-2} s^{-1} we find

$$n_d \simeq 4.3\times10^{-15} \text{ cm}^{-3}$$

and a dust density of $\sim 10^{-30}$ g cm^{-3}

Possible explanations

These numbers are very much lower than our crude model predicts, even if only silicate particles are considered. To explain this discrepancy, it may be that:

(1) MTS detectors are sensitive to only a small fraction of the interstellar dust particles which penetrate the Solar System;

(2) radiation pressure (or some other process) eliminates most of the particles that could have been detected by MTS; or

(3) the interstellar dust–gas ratio around the Sun is smaller than the galactic mean, which could be connected to the embedding of the Solar System in the 'intercloud' type of interstellar matter.

Consequences: (2) zodiacal light

We have also tried to compute the contribution to zodiacal light of solar light scattered by the interstellar particles inside the Solar System. Only spherical silicate particles were considered, on which the effect of radiation pressure was assumed to be negligible. For any point in the Solar System (r,θ) the emissivity $\varepsilon(r,\theta)$ is

$$\varepsilon(r,\theta) = n_d E(r,\theta)\,\sigma F_s\left(\frac{r_0}{r}\right)^2 \qquad (1)$$

where σ is the scattering cross section and F_s the solar flux at $r_0 = 1$ AU. If the scattering is assumed to be isotropic, the intensity is

$$I = \frac{1}{4\pi}\int \varepsilon(l)\,\mathrm{d}l \qquad (2)$$

If, therefore, all particles have the same σ, the zodiacal intensity caused by interstellar dust is proportional to $n_d\sigma$.

The intensity at 1 AU was computed in the direction of North and South ecliptic poles, as a function of Earth's position (or time of the year). It is shown in Fig. 4, together with observations[9] of zodiacal light collected by a photometer in the French satellite D2–A in the direction of North ecliptic pole during the year 1971–72. The solar flux in equation (1) was taken as $F_S = 6.2\times10^{13}$ photons cm^{-2} s^{-1} Å^{-1}, at the effective wavelength of the D2–A photometer (6,563 Å). The intensity is measured in S_{10} units (equivalent brightness of one tenth magnitude star per square degree; 1 S_{10} = 360 photons cm^{-2} s^{-1} Å^{-1} sr^{-1}).

The dashed line traced through the D2–A points represents the expected variation of zodiacal light, since the Earth's orbital plane does not coincide exactly with the symmetry plane of the zodiacal cloud[9]. The data points in November and December are ~ 15 S_{10} above this line. This 'bump' agrees with the maximum computed for light scattered by interstellar material. For the model computation, the value of $n_d\sigma$ was adjusted to 2×10^{-23} cm^{-1}, which also gives for the bumps computed for the North pole, a value of 15 S_{10}. The observations of zodiacal light in this direction therefore provide information about the product $n_d\sigma$. If the bump in the measurements is genuine, we have $n_d\sigma \simeq 2\times10^{-23}$ cm^{-1}. If the bump is accidental, this value for n_d becomes an upper limit.

Since the line of gravitational focusing lies ~ 7°S of the ecliptic plane, a stronger effect is expected in the direction of the South ecliptic pole, with an increase of ~ 50 S_{10} at the time of maximum (Fig. 4). Unfortunately, South ecliptic pole observations are hampered by the presence of the Magellanic clouds. For an observatory attached to the Earth, the strongest intensity of light by interstellar dust should be observed not far from the line of gravitational focusing. This would happen around December 1, when the Earth is at an ecliptic longitude $\gamma = 72°$, in the general anti-solar direction. For these conditions, the distribution of intensity scattered by interstellar material was computed with the use of equations (1) and (2) taking $n_d\sigma = 2\times10^{-23}$ cm^{-1}.

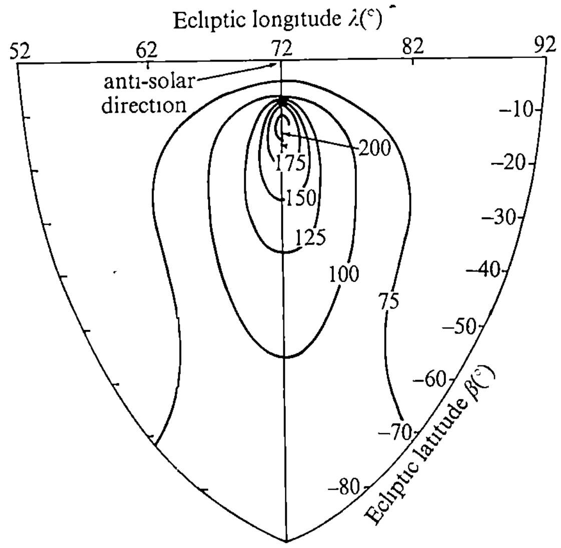

Fig. 5 Isophotes of the 'trail of light' (which would be superimposed on the zodiacal light pattern, when observed from Earth on December 1, south of the anti-solar direction) produced by the gravitational focusing of interstellar dust particles characterised by $n_d = 2\times10^{-23}$ cm^{-1}. Intensity levels are in units of S_{10} (see text).

The maximum intensity appears at the ecliptic longitude of $\gamma = 72°$, slightly south of the ecliptic latitude $\beta = -7°$ (which is the direction of gravitational focusing) because of the effect of perspective. As the longitude scale of Fig. 5 is five times larger than the latitude scale, the 'true' shape of such a conspicuous feature would be much narrower, like a pencil of light.

The maximum brightness of this feature, which would be superimposed on the usual zodiacal light pattern, is ~ 200 S_{10}, to be compared with a mean gegenschein brightness of 180 S_{10}. Unfortunately, gegenschein observations close to December 1 are scarce, because of a strong galactic background in the anti-solar direction at this time. From a long series of gegenschein observations obtained at Tenerife, however, Dumont (personal communication) estimated that if such a feature were brighter than 50 S_{10}, it would have been observed. Therefore, one can derive another upper limit for $n_d\sigma$, 5×10^{-24} cm^{-1}, which is more stringent than the one derived from the D2–A observations, and will serve as a basis for discussion in the following (if the November–December bump of D2–A observations was revealed to be connected with interstellar dust, one would have to explain this discrepancy with gegenschein observations).

Table 2 Parameters for the scattering of zodiacal light

Particle radius, a(10^{-8} m)	$x = \frac{2\pi a}{\gamma}$	Scattering cross section ρ (cm^{-2})	Particle mass (g)	Optical upper limit on n_d	$n_d m$ (g cm^{-3})
1.75	0.2	4.3×10^{-15}	5.6×10^{-17}	1.2×10^{-9}	6.7×10^{-26}
3.5	0.4	2.7×10^{-13}	4.5×10^{-16}	1.9×10^{-11}	8.5×10^{-27}
5.2	0.6	3.1×10^{-12}	1.5×10^{-15}	1.6×10^{-12}	2.4×10^{-27}
7	0.8	1.7×10^{-11}	3.6×10^{-15}	2.8×10^{-13}	1.0×10^{-27}
8.7	1.0	6.2×10^{-11}	7×10^{-15}	8.1×10^{-14}	5.7×10^{-28}

Discussion

As the scattering cross section σ is a strong function of the radius of particle a, the upper limit on $n_d\sigma$ gives an upper limit on n_d which is a function of a, or $x = 2\pi a/\lambda$ (Table 2). The optical characteristics of spherical silicate particles are taken from Wickramasinghe[10]: $n = 1.55, k = 0$, at $\lambda = 6{,}560$ Å.

Even with a particle radius approaching 0.1 μm (last line of Table 2), the optical upper limit on n_d, 8.1×10^{-14} cm^{-3}, is still ~ 20 times larger than that derived from the micrometeoroid rate as measured by MTS detectors. Optical observations do not therefore contradict, up to now, MTS observations.

Table 2 indicates that the penetration into the Solar System of interstellar silicate particles with an assumed number density of 1.5×10^{-12} cm^{-3} (as in our crude model) would have been observed optically only if these particles had a radius larger than 0.05 μm (which goes against our assumptions). This crude model is therefore consistent with the absense of a conspicuous 'trail of light' along the line of gravitational focusing. The best way to detect interstellar dust particles in the Solar System would probably be to launch a space probe equipped with micrometeoroid detectors on a trajectory intersecting the line of gravitational focusing.

We are indebted to Dr Alvarez for early communication of his results and to Dr Dumont, for discussions of his observations of zodiacal light.

Neutron diffraction measurements on isolated retinal rod outer segments show that most of the visual pigment protein, rhodopsin, is embedded in the hydrophobic core of the disk membrane. A very slight outward shift of protein at the cytoplasmic side of the membrane is associated with pigment bleaching.

STRUCTURAL analysis of retinal rod outer segment (ROS) membranes by X-ray diffraction has indicated that rhodopsin, which constitutes almost all the membrane protein, is partially or wholly immersed in the hydrophobic layer of the membrane, but details of its distribution are not unequivocally determined[1-7]. Differences in lamellar diffraction intensities between dark-adapted and bleached membranes[4,5] are interpreted as due to a small increase in electron density near the cytoplasmic (interdisk) side of the membrane. Movement of rhodopsin into the membrane on bleaching was deduced from measurements of diffraction in the plane of the membrane[8], but these measurements have been questioned[7]. Information from X-ray diffraction studies is limited by the imperfect stacking of the membranes, the low contrasts of electron densities among the components of the lipid–protein–water structure, and by the difficulty of placing electron density profiles on an absolute scale. Consequently, features in the electron density profile and changes on bleaching cannot be attributed with certainty to particular membrane components.

With the development of the high flux neutron beam facilities of the Institut Laue-Langevin, Grenoble, and the low angle scattering instrument D-11 (ref. 9), it has become possible to record neutron diffraction from small samples in times comparable with those of X-ray diffraction. A major advantage of neutron scattering studies is that the neutron scattering densities of biological membrane components are between those of H_2O and D_2O. Therefore, the range of contrast between the cytoplasm and the membrane can be varied from positive to negative by varying the H_2O/D_2O content of the Ringer's solution. The linear relationship between structure factors and D_2O percentage establishes the variation of phase of each order with contrast, using diffraction intensities from a single sample in at least three different H_2O/D_2O mixtures[10,11]. Furthermore, contrast variation data together with the existence of a clearly defined water layer provide an absolute scale of neutron scattering density. Using these neutron diffraction methods[12], we have obtained new, quantitative information on the distribution of proteins, lipids and water in the ROS disk membrane, and on structural changes associated with bleaching of the visual pigment.

Lamellar organisation in dark-adapted ROS membranes

Seven orders of lamellar neutron diffraction were measured in H_2O and 20%, 40% and 100% D_2O Ringer solutions from isolated frog rods prepared and oriented using a magnetic field, as described previously[7]. Figure 1 shows contour maps of neutron diffraction patterns: a D_2O pattern showing four lamellar diffraction orders (*a*); and an H_2O pattern with seven lamellar diffraction orders and diffuse scatter at right angles to the lamellar diffraction visible (*b*). Orders 1–4 are very intense in H_2O, 40% and 100% D_2O and are about 10 times larger than the higher orders. In 20% D_2O, which has a scattering density close to the average scattering density of the membrane, the pattern is very weak and orders 6 and 7 are prominent.

For phase assignment, the large range of contrast available

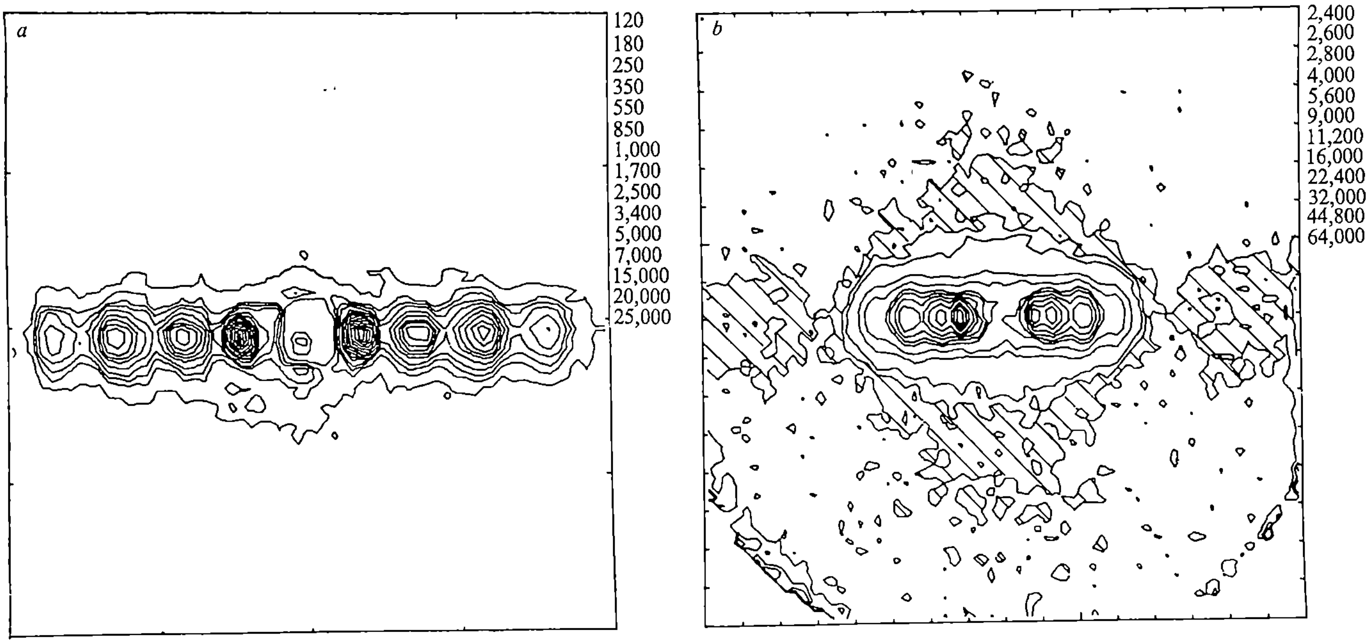

Fig. 1 Neutron diffraction patterns from freshly isolated frog ROS oriented using a magnetic field of 17 kgauss are shown in these contour maps of data obtained with the two-dimensional (64×64 cm) detector of the low angle scattering instrument D-11 at the Institut Laue–Langevin[9]. The contour lines connect points of equal diffraction intensity, and the numbers beside the maps refer to the number of counts in successive contour levels. The distribution of neutron wavelengths was triangular, with $\Delta\lambda/\lambda$ (FWHM)=8% Rods from 10–12 retinae were suspended in Ringer's solution, in a standard quartz spectrophotometer cell of 2 mm path length, and allowed to sediment in a horizontal magnetic field, forming an oriented pellet 1 mm thick. The long axes of the rods aligned along the field direction, and therefore the disk membranes were perpendicular to the field. The lamellar spacing was 295 Å, and the unit cell is centrosymmetric. *a*, Diffraction pattern in D_2O Ringer with a neutron wavelength of 9 Å. Four orders of lamellar diffraction are visible on each side of the central beam stop. The counting time was 10 min. The mosaic spread is less than 10° (FWHM). *b*, Diffraction pattern in H_2O Ringer, with a neutron wavelength of 4.4 Å Lamellar orders up to 7 and broad in-plane diffraction are visible. Order 1, is partly masked by the beam stop. The counting time was 1 h. Shading has been added to the region bounded by the lowest intensity contours to make order 7 and in-plane diffraction clearer.

enabled simple deductions: (1) In D_2O, every component of the membrane appears with negative contrast and orders 1–4 are prominent. Of all the possible phase factor combinations for those four orders, only one (−+++) gave a reasonable position in the unit cell, consistent with X-ray and electron microscopy results, for a negatively contrasting membrane. (2) In 20% D_2O, the relative neutron scattering densities of protein, phospholipid headgroups, hydrocarbon chains and Ringer's solution are close to their relative electron densities Therefore, the diffraction intensities and the phases should be the same for neutron scattering in 20% D_2O and X-ray scattering. In fact, the neutron diffraction pattern in 20% D_2O is very similar to the X-ray pattern. We conclude that the phases are also the same. The X-ray phases have been determined by osmotic swelling[3–5]. These phases for the neutron pattern in 20% D_2O and the linearity of structure factor with D_2O percentage (Fig 2) give the phase of each order at all contrasts The above two procedures gave consistent phase assignments for all orders except the very weak fifth order. An experiment with osmotic shrinking in D_2O indicated the presence of a zero in the

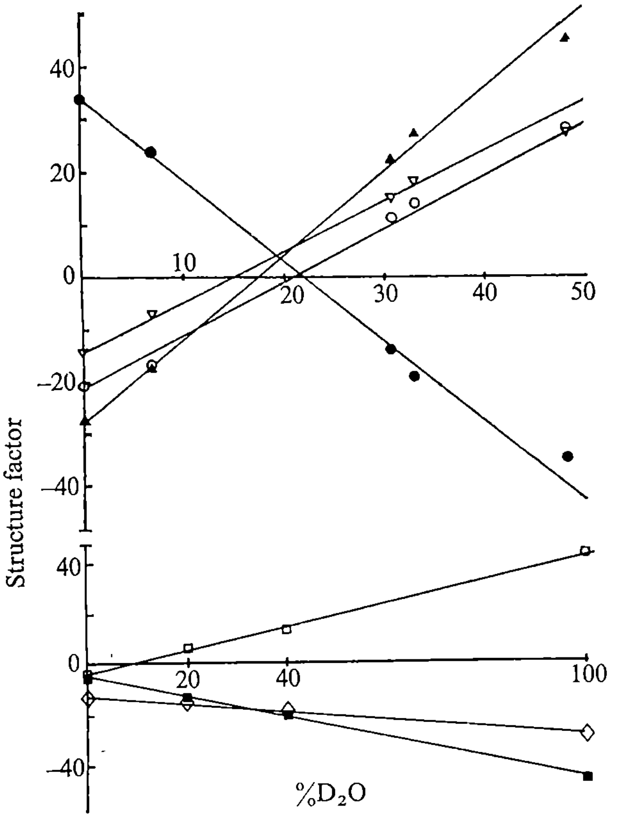

Fig. 2 Contrast variation. Structure factors 1–7 are plotted against the D_2O percentage of the Ringer's solution to establish phase changes between H_2O and D_2O. The data for orders 1–4 (●,1; ○,2; ▲,3; ▽,4) were measured with the same sample, to keep a fixed intensity scale. To change the contrast at the end of a measurement, a known amount of the supernatant solution was removed from the sample cell without losing or bleaching any rods, and replaced by a different solution. The rods were then resuspended in the new mixture, reoriented in the magnetic field and allowed to resediment. This process was completed in a few minutes. Orders 5–7 (□,5; ■,6; ◇,7) were scaled from longer measurements on other samples by normalising to order 3. Intensities (I_h) were obtained by integrating the lamellar diffraction peaks over their arcs of mosaic spread, and multiplying by a Lorentz factor of h, giving structure factors $F_h=\sqrt{(hI_h)}$ To obtain the intensities of the higher orders, the peak shapes along the lamellar axis were approximated by Gaussians of half-width calculated from the beam size, wavelength broadening and natural widths due to the lattice disorder (natural widths obtained from X-ray data). In 20% D_2O, both the intensity, which was very weak, and the phase of order 5, were uncertain

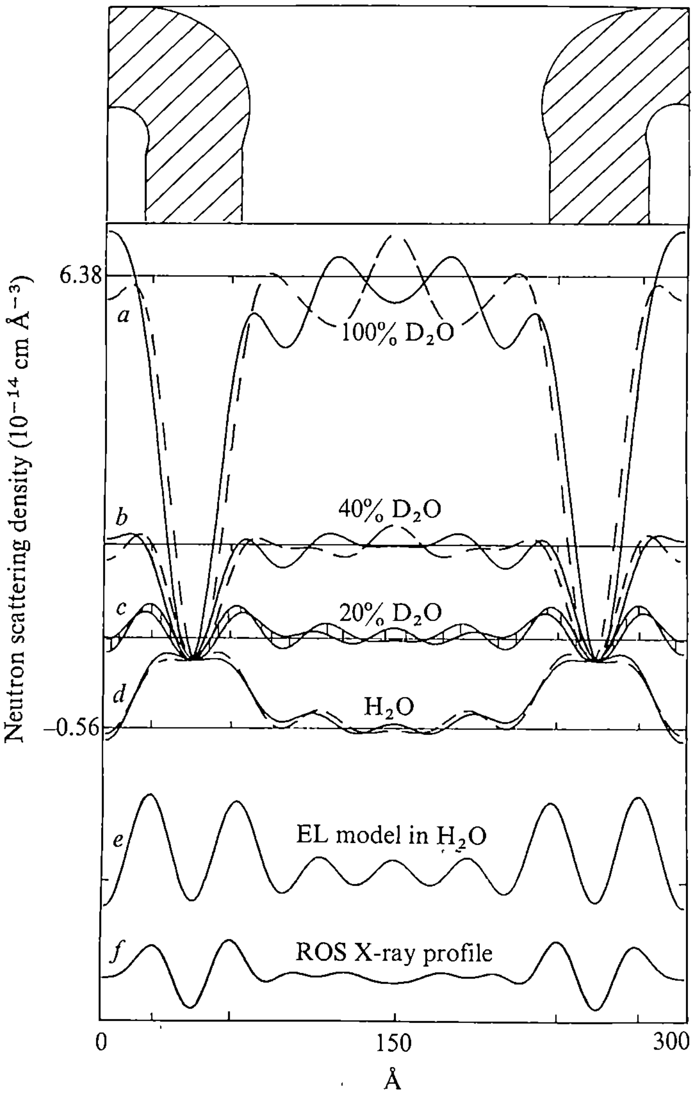

Fig. 3 *a–d*, Neutron scattering density profiles of ROS computed with seven orders of diffraction, in 100% D_2O, 40% D_2O, 20% D_2O and H_2O Ringer's solutions. Structure factors used are those shown in Fig. 2. – – – – –, Alternative phasing of order 5 Order 5 is taken as zero in the 20% D_2O profile (*c*), with upper and lower limiting profiles shown. Absolute density scaling: The structure factors were scaled as described in Fig. 2. Relative positions of the profiles were established by making the H_2O and 40% D_2O profiles coincide at the centre of the membrane, assuming no water penetration at that point. Up to 10% water penetration at the centre of the membrane changes the scale negligibly. The H_2O and 40% D_2O water levels were then used to define the absolute density scale. The other profiles were then set on this scale without further adjustment. The assumption of a carbohydrate content in the cytoplasm of 20 g 100 ml^{-1} (ref. 15) shifts the scale slightly. Protein and lipid headgroups have neutron scattering densities about equal to that of 40% D_2O, whereas lipid hydrocarbon chain scattering density is close to that of H_2O, increasing slightly with unsaturation. In 40% D_2O, the only component of the membrane contrasting with the Ringer's solution is the paraffin chain region. The small width observed (27.5 Å FWHM) of the density profile at this contrast confirms the presence of a lipid bilayer. This width is 60 Å in H_2O, and 32 Å in D_2O. *e*, Model density profile derived from egg lecithin bilayer neutron scattering data in H_2O (ref. 14), calculated for the same resolution and unit cell as the ROS data. The main difference between profiles *d* and *e* reflects the presence of rhodopsin in *d*, indicating that a considerable fraction of the protein must be inside the bilayer. *f*, Electron density profile of ROS (ref. 7), computed with ten orders, showing the polar headgroup positions. Computed with seven orders, it is identical to *c*. Density scales for *e* and *f* are arbitrary.

Fourier transform between orders 1 and 2, and tended to favour a positive sign for order 5 in D_2O. The phasing of orders 1–4 also agrees with that determined by Yeager in neutron diffraction experiments on intact retina[13].

Neutron scattering density profiles of ROS computed with 7 orders are shown in Fig 3, on an absolute density scale. The profile in H_2O (*d*) is markedly different from the neutron scattering density profile of phospholipid bilayers (*e*) and myelin[14] at the same resolution, in that it shows a fairly flat distribution of scattering density across the membrane instead of a pronounced dip at the centre. In the ROS, the scattering density at the centre of the membrane is matched by the fluid medium when the Ringer's solution contains 15% D_2O. This means that the non-exchangeable material in the hydrophobic region has the scattering density of 15% D_2O, or 18% D_2O if one allows for 20 g carbohydrate per 100 ml cytoplasm[15], independent of the amount of water penetration or proton exchange. Taking the average ROS fatty acid chain composition for frog ROS of 18 : 2 (calculated from ref 16), we find that about one-third of the volume in the hydrophobic region consists of protein. This could account for all of the protein. The water penetration in the membrane, assuming none at the centre, is given by the difference between the D_2O and H_2O profiles. From the variation in scattering density in the polar headgroup region (located by the electron density profile) we find that this region is about one-half water by volume.

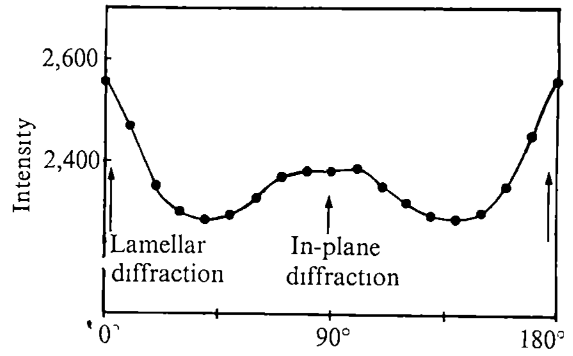

Fig. 4 The broad in-plane diffraction is shown by this azimuthal scan of the diffraction intensity at a reciprocal spacing at about (50 Å)$^{-1}$ from ROS in H_2O Ringer's solution The origin of the angular scan is in the lamellar direction.

Equatorial diffraction

Diffraction in the direction perpendicular to the lamellar diffraction arises from interference between neighbouring rhodopsin molecules in the plane of the membrane. Diffuse equatorial diffraction centred near (50 Å)$^{-1}$ has been observed in X-ray diffraction studies[1,3,7]. We measured in-plane diffraction in H_2O (Figs 1*b* and 4) It was much less clear in D_2O because of the very intense lamellar diffraction, and we could only estimate an upper limit for its intensity, which was about equal to the H_2O in-plane intensity. On an absolute scale, the equatorial intensity in 40% D_2O is within a factor of two of that in H_2O. These observations show that the in-plane intensity is insensitive to the scattering density of the fluid medium. Consequently it must primarily arise from protein–hydrocarbon chain contrast within the membrane. Allowing for uncertainties in these intensity measurements, we estimate that less than one-third of the protein volume is contrasting with the aqueous medium. The limit is mainly set by the measurement in 40% D_2O, where the protein–cytoplasm contrast is very small.

Structural changes on bleaching

To investigate structural changes associated with total bleaching of rhodopsin, we recorded continuous sequences of spectra within a few minutes from dark-adapted samples

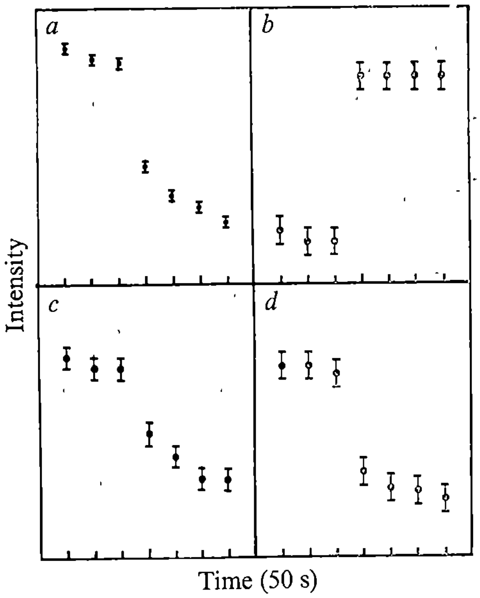

Fig. 5 Intensity changes on bleaching for the first 4 orders of diffraction in 100% D_2O. Orders: *a*, 1; *b*, 2; *c*, 3; *d*, 4. The sequence of 50-s measurements was carried out on the same sample, which was exposed to light after the third measurement. Intensity changes amounted to 10% in order 1, 15% in 2, 7% in 3, and 10% in 4. Changes of comparable magnitude were observed in H_2O Ringer's solution, but the changes were much smaller in 40% D_2O Ringer's solution.

which were bleached in the middle of the sequences. In H_2O and D_2O, small but significant intensity changes were observed in the first 4 orders. In the weaker orders 5–7 the changes were too small to be measured in a short time. Bleaching had very little effect on the pattern in 40% D_2O. The bleaching sequence in D_2O Ringer's solution is shown in Fig. 5.

Since orders 1–4 are very intense at the above three contrasts, the small intensity changes observed on bleaching are most unlikely to be accompanied by phase changes. This is not the case with X rays, where order 2 is close to zero before bleaching and increases after bleaching, so that the difference profile is not uniquely defined. Neutron scattering density profiles in H_2O and D_2O and their changes on bleaching are shown in Fig. 6.

Although the differences between the profiles are smaller than the Fourier cutoff ripples, the differences are significant because they come from significant changes in the structure factors (Fig. 5). The observed effects are not accounted for by changes in *d* spacing, since X-ray diffraction experiments have shown that such changes in isolated rods are small and transient, with no net change in the time scale of our experiments (Fig 2 of ref. 17). Furthermore, the minimal changes in 40% D_2O rule out a shift of the lipid bilayer within the unit cell. Protein, however, has the same scattering density as 40% D_2O and the observed changes on bleaching are consistent with an outward shift of protein at the cytoplasmic side of the membrane. Quantitatively, the observed change in the profile can be accounted for by a shift of the centre of gravity of the protein by about 1 Å.

Conclusions

Our essential finding is that the shape of the ROS neutron scattering density profile in H_2O is not dominated by the bilayer arrangement of the lipids, as for the X-ray profile, and the contribution of protein to the structure is clearly seen. From the density profiles we calculate that a lower limit of 20% of the volume of the hydrophobic region consists of protein, allowing for uncertainty in the scattering density level at the centre of the membrane due to Fourier cutoff effects and the possible presence of carbohydrate in the cytoplasm. This accounts for 50% of the total rhodopsin. Our upper limit locates all the rhodopsin in the hydrophobic region, which would then contain 35% protein by volume. The profiles also indicate a slight asymmetry in the membrane, with protein probably extending into the cytoplasmic space, but not into the intradisk space.

Since contrast variation was done without adding molecules which could be excluded from regions of hydrated protein, like sucrose, but merely by isotopic exchange of water, dry protein mass was observed. The part of the protein which extends outside the hydrocarbon chain region could be highly hydrated. There is definitely a large water penetration in the lipid headgroup region.

Insensitivity of equatorial diffraction to the scattering density of the Ringer's solution confirms that most of the protein is inside the membrane. These results on ROS membrane structure show that the electron density profile obtained from X-ray diffraction[1–7] should be interpreted as the electron density variation of the lipid bilayer, superimposed on a fairly uniform protein contribution

The changes observed on bleaching of rhodopsin in our experiments agree with the X-ray results[4,5,7]. Furthermore, the contrast variation results identify the observed change as an outward shift of protein at the cytoplasmic side of the membrane. It cannot be decided whether this is due to a very small shift of the entire protein molecule or to a larger displacement of a small part of the protein. It seems that the only other evidence for a structural change in the intact membrane comes from small birefringence changes on bleaching[15], and, more specifically, for the protein in the

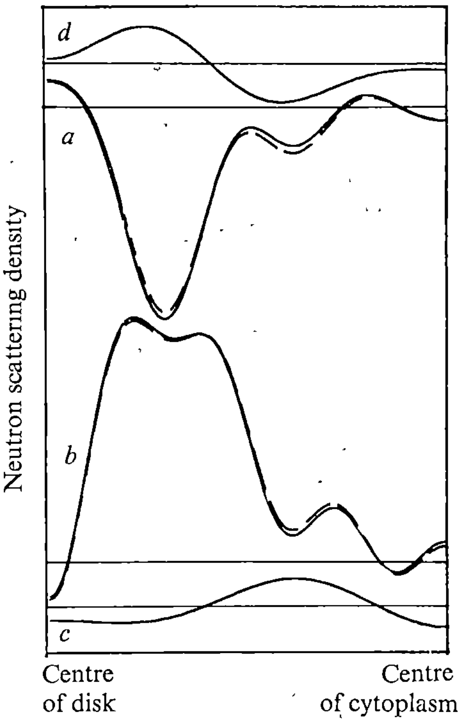

Fig. 6 Scattering density profiles of ROS disks before (——) and after (– – – –) bleaching, and their difference profiles (×5), (bleached – unbleached). Changes in orders 1–4 have been included in this computation. Changes in orders 5–7 are smaller and are not included in the difference profiles. The H_2O and D_2O data are on different density scales. *a*, In D_2O Ringer's solution. *b*, in H_2O Ringer's solution; *c*, H_2O difference profile (×5); *d*, D_2O difference profile (×5). The increase in density at the intradisk side in the D_2O profile may be accounted for by a shift of D_2O into that region, resulting from increased hydrogen–deuterium exchange on bleached rhodopsin[18].

membrane, from the observation of changes in the hydrogen exchange kinetics on bleaching[18].

On being close to a black hole without falling in

I SHOW here that for any $\varepsilon > 0$ it is possible for a magnetic field to hold plasma in equilibrium at a radius $r_0 = r_g(1+\varepsilon)$ relative to a Schwarzschild black hole of (radius r_g) and that this equilibrium need not be subject to the kind of relativistic instability that destroys circular orbits of radius $r < 3r_g$. (Putting $c = G = 1$, $r_g = 2M$ is the radius of the event horizon of a hole of mass M.) Astrophysical plausibility does not stop ε from being much smaller than unity.

Normal indices refer to Schwarzschild coordinates, whereas barred indices refer to the corresponding orthonormal tetrad and label physical quantities which can be measured by observers at rest relative to the hole. Suppose there is a thin disk of matter at rest in the $\theta = \pi/2$ plane with current density $J_{\bar{\varphi}}$ and energy density ρ as measured by an observer at rest in the disk. The current is to interact with a magnetic field $B_{\bar{\theta}}$ to produce a Lorentz force balancing gravity. I shall assume that both the matter and the field have negligible gravitational effect, so that the Schwarzschild metric is valid. Then

$$T^{r\beta}{}_{,\beta} = (\rho+p)M/r^2+\partial p/\partial r-2p\left(1-\frac{2M}{r}\right)/r$$

Here p is the gas pressure. I shall assume that the plasma is not highly relativistic, so that $p \ll \rho$ and $T^{r\beta}{}_{,\beta} = \rho M/r^2$. Taking the radial component of the equation of motion $T^{\alpha\beta}{}_{;\beta} = F^{\alpha\beta}J_\beta$ and integrating with $r\mathrm{d}\theta$, I obtain

$$\begin{aligned}\sigma M/r^2 = F^{r\beta}I_\beta &= (1-(2M/r))^{\frac{1}{2}}F^{\bar{r}\bar{\varphi}}I_{\bar{\varphi}}\\ &= (1-(2M/r))^{\frac{1}{2}}(-B_{\bar{\varphi}})I_{\bar{\varphi}} \qquad (1)\end{aligned}$$

where σ and $I_{\bar{\varphi}}$ are the energy and current surface densities.

Suppose for simplicity that the magnetic field is mainly generated far from the hole so that near the hole it seems to be uniform. Suppose this 'uniform' field has magnitude B_∞ and points in the $\theta = 0$ direction at infinity. Then $B_{\bar{\theta}} = -(1-(2M/r))^{1/2}B_\infty$ on $\theta = \pi/2$ (ref. 1). The field generated by the local current is of the order $(1-(2M/r))^{1/2}I_{\bar{\varphi}}$ except where $I_{\bar{\varphi}}(r)$ varies rapidly, for example at the edge of a current disk[2]. For consistency it should be assumed that $I_{\bar{\varphi}}(r) \ll B_\infty$ and varies smoothly. This is not an important restriction as boundary conditions at the event horizon require $B_{\bar{\theta}} \simeq B_\infty(1-(2M/r))^{1/2}$ close to the event horizon, B_∞ being a constant[2], and the only place one might expect $I_{\bar{\varphi}}$ to be discontinuous is at the inner edge of the disk, where the effect would be to make $B_{\bar{\theta}}$ more negative, and thus to oppose gravity. Substituting the assumed form for $B_{\bar{\theta}}$ into equation (1)

$$(\sigma/I_{\bar{\varphi}})M = (r^2-2Mr)B_\infty \qquad (2)$$

Let $\sigma/I_{\bar{\varphi}} = \alpha(m_p/ce)$, where m_p and e are the mass and charge of a proton. m_p/ce is the dimensionless number 8.99×10^{-19} when $c = G = 1$. Clearly $\alpha > 1$. If the electrons and protons are streaming relative to each other with a relativistic velocity, their kinetic energy contributes to σ, and if two-stream instability is to be avoided the plasma must be relativistically hot, which also increases σ. The relativistic current would cause a significant mechanical stress $T^{\varphi\varphi}$, which because of the curvature of the coordinate system would contribute to the radial balance equation as a force opposing gravity; this is just the centrifugal force from the circular motion of the particles. I shall assume that the current is nonrelativistic (so that $T^{\varphi\varphi}$ is not significant near the event horizon) and take $\alpha \gtrsim 10$. Fixing α at its lower limit in equation (2) and solving for r, I obtain r_0, the smallest radius at which matter can be stationary, given B_∞ and M

$$\begin{aligned}r_0/r_g &= (1+(1+4\varepsilon)^{1/2})/2,\\ \varepsilon &= 5.3\alpha(B_\infty/1\ \text{gauss})^{-1}(M/M_\odot)^{-1} \qquad (3)\end{aligned}$$

If $\varepsilon \ll 1$, $r_0/r_g \simeq 1+\varepsilon$. If the field is a significant gravitational source $B_\infty \gtrsim 10^{19}(M/M_\odot)^{-1}$ gauss. Hence B_∞ can be large enough for $\varepsilon \ll 1$ without being so large that the Schwarzschild metric is invalid.

This result does not contradict Gibbons' limit on how near to a black hole a rope can be lowered[3]. Gibbons' rope has constant energy density per unit length. By the weak energy condition this gives an upper limit on the tension the rope can take without breaking. Tension is greatest at the top end of the rope, but gravity exerts its greatest force on the energy present at the bottom of the rope. The rope breaks at the top. This can be avoided by strengthening the rope at the top and lightening it at the bottom, for example by lowering a tapered rope. This is effectively happening here. The magnetic field can be regarded as a medium with pressures and stresses. The energy in a spherical shell of radius r and unit thickness $\sim r^2B_\infty^2$. There is only a small amount of energy near the hole requiring support, and a lot of energy to take the strain far away from the hole. Hence equilibrium is possible.

It only remains to consider stability. Distant field sources can be expected to vary on time scales much longer than the free-fall time near the hole. I shall therefore take the uniform, externally imposed part of the field to be constant. Because of high

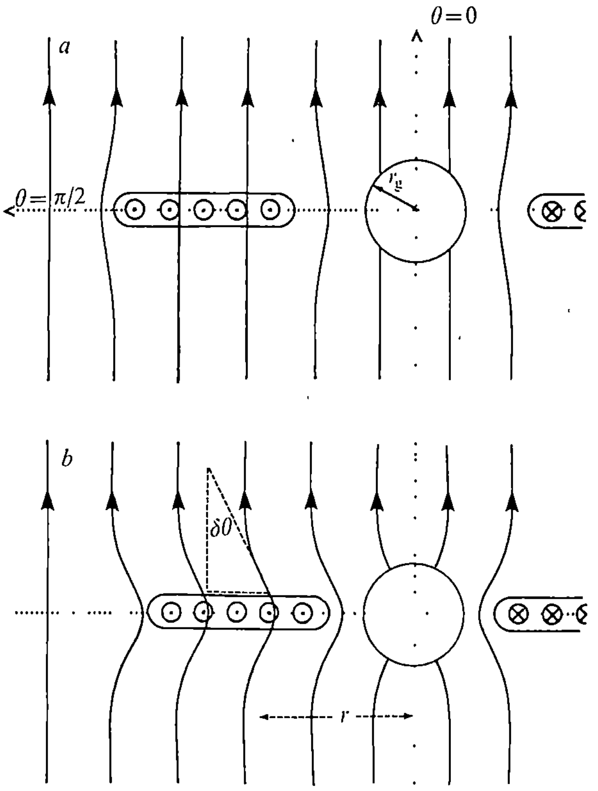

Fig. 1 *a*, Cross section of current disk and black hole in unperturbed state. Large circle is the event horizon of the hole. Small circles with dots denote current coming out of the paper etc. The magnetic field lines are lines of constant $A_\varphi \simeq (B_\infty/2)r^2 \sin^2\theta$ *b*, Perturbed state. Field lines are frozen into the disk and at infinity. A field line through an element of the disk displaced a radial distance δr will be similarly displaced. At the disk surface the line is rotated through an angle $\delta\theta$ as seen on this diagram—a local observer would see it rotated through an angle

$$\overline{\delta\theta} = \delta\theta(1-(r_g/r))^{-1/2}$$

conductivity, any perturbation of the plasma drags the field lines with it. The perturbed field consists of the original uniform field and a perturbation field generated by currents in the plasma. For a given perturbation, the electromagnetic energy increases by an amount proportional to ${B_\infty}^2$, while the decrease in gravitational potential energy is fixed. Thus the perturbation is stable if B_∞ is large enough. Equation (1) yields

$$\left(\frac{\sigma}{-B_{\bar{\theta}}}\right)M = r^2(1-(2M/r))^{1/2}I_{\bar{\varphi}} \qquad (4)$$

Consider a perturbation (not necessarily axisymmetric) that takes a fluid element from r to $r+\delta r$, and does not extend over a length scale$\gg r$. For that element the left-hand side of equation (4) stays constant, because surface energy and flux satisfy identical conservation laws. The perturbation is stable if, and only if, the right-hand side increases. When unperturbed the field lines (from a static observer's viewpoint lines of constant covariant vector potential $A_\varphi(r,\theta)$) are nearly straight (Fig. 1*a*). Because the perturbation field is approximately dipolar at heights$\gg r$ above the disk the field lines there will also be almost straight (Fig. 1*b*). This gives a lower limit on the angle $\delta\theta$ through which the field lines have been rotated near the disk: $\delta\theta \gtrsim (-\delta r)/r$, and implies $\delta I_{\bar{\varphi}} \gtrsim B_\infty(-\delta r)/r$. Close to the hole the disk would seem to be stable if $I_{\bar{\varphi}} \lesssim 2B_\infty(1-(2M/r))^{1/2}$.

For a stellar black hole $M \simeq 10M_\odot$, while for a black hole in a galactic nucleus or QSO $M \simeq (10^8\text{–}10^9)M_\odot$. Typical interstellar fields have magnitudes of only $\sim 10^{-5}$ gauss, but fields frozen into accreting plasma get amplified by many orders of magnitude[4], so that B_∞ is in fact much greater. Small scale fields dissipate faster than large scale fields. It is possible that plasma is in quasi-static equilibrium near to some black holes. This is a consequence of m_p/ce being a small number, that is, of the strength of electromagnetic forces compared with gravity.

I wish to thank Professor M. Rees and Drs R. Blandford and F. Lamb for many useful conversations. I acknowledge an SRC studentship.

Outbursts of the recurrent nova T Coronae Borealis

THE recurrent nova T CrB has long been regarded as an anomaly among cataclysmic variables. It is a binary system consisting of an M3III giant and a blue companion[1]. From the radial velocity curves, Kraft[2] found component masses of $\geq 3.7M_\odot$ and $\geq 2.6M_\odot$, respectively, later revised downwards to $2.6M_\odot$ and $1.9M_\odot$ by Paczyński[3]. Nevertheless, the mass of the blue component is clearly greater than the Chandrasekhar limit, even though the blue components of common novae are widely believed to be white dwarfs. The binary period, 227.5 d, is > 300 times longer than that of GK Per[3], the longest period known among the remaining cataclysmic variables, and in stark contrast with the 0.0567-d period of WZ Sge, the only other recurrent nova of known binary period. Warner[4] has suggested, however, that T CrB is typical of the majority of recurrent novae. In this paper we interpret the behaviour of T CrB in terms of accretion in a binary system.

Two outbursts of T CrB have been observed, in 1866 (JD 2,402,734) and in 1946 (JD 2,431,861), these being apparently remarkably similar[5]. In neither case was the eruption detected before the nova was already declining in brightness, but evidence exists suggesting that the initial rise is extraordinarily rapid[6].

The brightness variations in this system in the interval immediately surrounding the 1946 outburst[7,8] are shown in Fig. 1. Three features are clearly visible in the light curve: (1) There is a sudden decrease in brightness by about one magnitude (visual) to a minimum, $m_v \simeq 10.8$, at JD 2,431,599. What scattered observations exist of this phenomenon suggest that superimposed on the recovery from minimum is a decaying oscillation with period ~ 41 d and initial amplitude, $\Delta m_v \simeq 0.15$; (2) 263 d later, the principal maximum, $m_v \simeq 3.4$, occurs. The system remains within one magnitude of maximum for approximately three days only, and the decline is exceptionally rapid (0.5 mag d^{-1}). The total energy output in visual light during this outburst amount to ~ 1,400 times the mean daily output of the giant component[5] ($m_v \simeq 10.2$) in a quiescent state; (3) 106 d following the principal maximum, the system again begins brightening, reaching a secondary maximum, $m_v \simeq 8.06$, near JD 2,432,020, with fluctuations at maximum of a few tenths of a magnitude. The system drops to $m_v \simeq 9.4$ within the next 80 d, followed by an extremely prolonged decline[9] ($\geq$ 25 yr) to its present light level, $m_v \simeq 10.15$ (personal communication from J. A. Mattei).

This outburst behaviour carries the distinct signature of an episodic accretion event. The minimum preceding outburst is associated with the dynamical ejection of a coherent mass of gas by the lobe-filling giant. Bath[10] has shown the existence of such an instability generally among lobe-filling giants, and

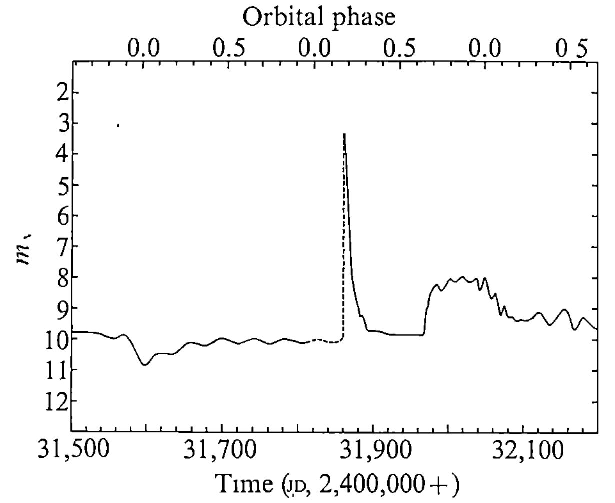

Fig. 1 The light curve of T CrB during the 1946 outburst, reconstructed from visual observations by members of the AAVSO (ref. 7). The dotted portion of the curve near JD 2,431,840 represents a gap in observational records while T CrB was unfavourably located with respect to the Sun. The observations shown before the outburst are those of a single observer, L. C. Peltier. The oscillations shown in this portion of the light curve are suggested by his observations, but the number of observations is relatively small. There is unusually large observational scatter after JD 2,432,070, suggesting an enhanced level of rapid photometric activity. The orbital phases indicated at the top of the figure are computed from an ephemeris by Paczyński[3].

time-dependent calculations of such events find the mass-losing star underluminous following the ejection[11]. The recovery from minimum is characterised by a timescale[11]

$$\tau_{th} \simeq \frac{RT\Delta M}{\Delta L}$$

where R is the ideal gas constant. A lobe-filling M3III giant[12], $T_e = 3{,}350$ K, has a luminosity $L_g = 1{,}250 L_\odot$. Taking $\Delta L \simeq L_g$, and assuming a mean temperature, $T \simeq 10^5$ K, for the ionisation zones, the observed timescale, $\tau_{th} \simeq 100$ d, indicates $\Delta M \simeq 10^{-3} M_\odot$ transferred. The possible 41-d periodicity superimposed on the recovery is consistent with a low order pulsational mode of the giant (P. R. Wood, personal communication), excited by the ejection episode.

The principal maximum is of such short duration that it must correspond to a dynamical phenomenon. The matter ejected by the giant initially takes up an extremely eccentric orbit around the secondary. This orbit is made circular dynamically, by supersonic collisions within the orbiting material. A simple estimate, following Lubow and Shu[13], indicates that 1.09×10^{14} erg g^{-1} is dissipated in this way for the adopted binary parameters. Allowing a bolometric correction of 1.81 mag for the giant[12], the visual energy output is found to be 1.12×10^{44} erg by comparison with the quiescent giant luminosity, giving $\Delta M = 5.2 \times 10^{-4} M_\odot$, in good agreement with the estimate obtained above. The resultant circular orbit has a radius $R_d = 19.9 R_\odot$, period 7.49 d.

Viscous dissipation within this accretion ring broadens it into a disk which gradually reaches down to the surface of the accreting star[14]. As it does so, its luminosity increases, reaching a maximum as its inner edge reaches the surface of the central star. The height of that maximum is a direct measure of the surface potential of the star, and the interval between the principal and secondary maxima reveals the viscous timescale of the disk.

The secondary maximum of T CrB clearly reveals the secondary as a main-sequence star (first suggested by Plavec[15,16] and Harmanec[17]). The mass and luminosity of the giant component indicate an age[18] of $\sim 4.7 \times 10^8$ yr for the system, placing the main-sequence companion in core hydrogen burning ($X_c \simeq 0.28$), with radius $R \simeq 1.81 R_\odot$. In the time-dependent, constant-viscosity disk model[14], the interval between the creation of an accretion ring (primary maximum) and the point at which the light level rises to within 1.5 mag of secondary maximum (an observationally well defined quantity) is $\Delta t = 0.118\ \tau_v$ where τ_v is the natural viscous timescale

$$\tau_v = \frac{R_d^2}{6\nu}$$

Thus, the viscous timescale of the accretion disk in T CrB is $\tau_v = 930$ d. The predicted height of secondary maximum for the assumed main-sequence companion is $m_v = 7.77$, in good agreement with the observed maximum (8.06 m), and far lower (by more than five magnitudes) than that expected for a massive white dwarf companion. The effective Reynolds number of the disk is

$$R_v \simeq 6 \left\{ \frac{GM_2}{R_d^3} \right\}^{1/2} \tau_v \simeq 4{,}700$$

indicating that the disk is turbulent.

Dwarf novae are widely believed to be accretion episodes of a very similar kind[19,20]. Bailey[21] has recently found an empirical relationship among dwarf novae between the rate of decline from maximum and the orbital period, P

$$\tau \simeq 9.2 P$$

where τ is the time required to decline one magnitude. For T CrB, the inferred timescale, $\tau = 2{,}090$ d, is in excellent agreement with the time required for a theoretical constant-viscosity disk with $\tau_v = 930$ d to decline from one magnitude below maximum to two magnitudes below maximum, $\Delta t = 2{,}320$ d.

Details of this model, and a reinterpretation of Kraft's observations[2] will be published separately. The author gratefully acknowledges invaluable discussions with J. W. Truran, R. P. Kraft, G. T. Bath, J. E. Pringle, and P. R. Wood. Special credit is due to the many amateur astronomers throughout the world, and the American Association of Variable Star Observers (AAVSO) and its Director, Janet Mattei, in particular. Without their patient observations this discovery would not have been possible. This research was supported by the NSF.

A plum-pudding model for interstellar grains

THERE seem to be two basic mechanisms by which interstellar grains can grow; the condensation of gaseous molecules (mostly of the CNO type) on to their surfaces and the coagulation on collision of individual grains. In general, as has been shown by Simons and Williams[1], condensation leads to a more rapid growth rate than coagulation resulting from the thermal motion of the grains. If, however, relative motions can be set up within the grain population, then this increases the collision rate and so also increases the rate of growth by coagulation. Now, for small grains, the force on them from radiation pressure depends on a different function of the grain radius, a, than does the viscous drag generated by the ambient gas. (For simple models these functions are respectively a^3 and a^2.) Consequently, grains of differing sizes will be caused to move with different velocities through the ambient gas by radiation, the larger ones moving faster. This causes these grains to capture further grains by coagulation which in turn enhances their relative velocity even further. The purpose of the present communication is to show that this growth caused by radiation pressure coagulation is probably of the same order as that from gas atom condensation, and to point out an important consequence of this.

Let us focus attention on a particular grain, G. Atoms will be incident on this grain both in the form of free atoms and in the form of those bound in other grains. In each case the number of atoms Z adhering to G per unit time will be given by

$$Z = vnA\sigma$$

where v is the velocity of the incident atoms relative to G, n is the number of these atoms per unit volume, A is the effective cross section of G and σ is the sticking coefficient. Thus the ratio of grain growth from condensation to that caused by radiation pressure coagulation is given by

$$X \simeq \frac{v_a n_a A_a \sigma_a}{v_g n_g A_g \sigma_g} \tag{1}$$

where the subscripts a and g refer, respectively, to free atoms and to those bound in grains.

To calculate v_g we note first that due to its charge, prolonged grain motion can only occur parallel to the magnetic field **H**. In this direction, the force on grains of radius a from radiation is given by

$$F_R = \pi a^2 Q(a) P \beta \tag{2}$$

where P is the radiation pressure and β the cosine of the angle between **H** and the direction of the radiation pressure. $Q(a)$ is the mean efficiency factor for radiation averaged over all frequencies. For blackbody radiation characterised by a temperature of $\sim 10^4$ K, such as may typically be found in the Galaxy, acting on a grain composed of material with a complex refractive index

$$Q(a) \simeq 5 \times 10^4 a \tag{3}$$

(see Simons and Williams[2], Greenberg[3]), for all values of a such that $Q(a) \leqslant 1$. Simons and Williams[2] have shown that for the general galactic radiation field

$$P \simeq 1.2 \times 10^{-13} \text{ (cgs units)}$$

and that the gravitational field of the interstellar cloud within which the grain is situated is unimportant as far as the motion of that grain is concerned. Also since the galactic field acts equally on grain and cloud, in any discussion of their relative motion it may be ignored. The relative velocity of the grain is thus determined by balancing the driving radiation pressure by the viscous drag of the ambient gas which has the form (Baines *et al.*[4])

$$F_{Res} = \pi a^2 \rho v W \gamma \tag{4}$$

v being the relative velocity, W the mean thermal velocity and ρ the gas density. γ is a factor, numerically of order unity, which depends on the way gas molecules are reflected from the surface of the grain. For typical interstellar clouds (see Lequeux[5]) we find that

$$F_{Res} \simeq 4.5 \times 10^{-18} \pi v a^2 \tag{5}$$

and from equations (2) and (5) we get

$$v \simeq 1.3 \times 10^4 Q(a) \tag{6}$$

taking $\beta = \frac{1}{2}$. Thus the relative velocity of two species of grain of radii a_1 and a_2 is given by

$$v = 7 \times 10^8 (a_1 - a_2) \tag{7}$$

the larger grains moving faster than the smaller ones. Since we are concerned with the growth of grains to their present size we take as representative values $a_1 \simeq 4 \times 10^{-6}$ cm and $a_2 \simeq a_1/2$. This yields

$$v_g \simeq 15 \text{ m s}^{-1} \tag{8}$$

As far as v_a is concerned, we suppose the atoms to be predominantly oxygen and the gas temperature to be ~ 100 K. This gives $v_a \simeq 300$ m s^{-1}, so that

$$v_a / v_g \simeq 20 \tag{9}$$

As far as n_a/n_g is concerned, it is generally assumed that the mass of heavy condensible atoms is roughly equally divided between free atoms and those bound in grains. In view of this we shall take

$$n_a / n_g \simeq 1 \tag{10}$$

It is generally supposed that atoms such as C and Si are precominantly bound in grains so that the ratio n_a/n_g may well be < 1, though values > 1 cannot be entirely ruled out.

A_a will be the geometric cross section πa^2 of the grain G with radius a. If the other grains incident on it have radius a', then

$$A_g \simeq \pi (a + a')^2$$

Now a' can be both greater or smaller than a, so that a reasonable estimate is presumably made by setting $a' = a$. This gives

$$A_a / A_g \simeq 1/4 \tag{11}$$

The value of σ_a has been estimated theoretically for O atoms (in ref. 6) to be $\sigma_a \simeq 0.3$. The best available evidence for σ_g would seem to be from experiments on the acoustic coagulation of terrestrial aerosols[7]. In these experiments coagulation proceeded efficiently for all relative grain velocities involved, which ranged up to several m s^{-1}. Since v_g (equation (8)) is greater than these velocities only by a factor ~ 3, we suggest taking

$$\sigma_g \simeq 1$$

in the absence of any evidence to the contrary. This gives

$$\sigma_a / \sigma_g \simeq 0.3 \tag{12}$$

Pure Chemistry Library
SCIENCE COLLEGE.
[illegible] Circular Road

It then follows from equations (1), (9), (10), (11), (12) that

$$X \simeq 2 \qquad (13)$$

In spite of the various uncertainties in the above estimation the result (equation (13)) would seem to substantiate our contention that growth from radiation pressure coagulation is probably of the same order as that from condensation. This has a very important consequence since it leads to the possibility of the formation of a grain possessing a novel type of internal structure; we call this a "plum-pudding" grain.

Initially a grain with a single silicate type nucleus will build up an ice mantle by condensation. Collision with a similar grain followed by coagulation will lead to a larger grain consisting of two separate silicate type cores surrounded by ice. As growth by both mechanisms proceeds, a multicored grain of silicates and similar material embedded in an ice matrix is formed, similar to plums in a pudding.

Such a grain would have rather novel optical characteristics, the main feature being that it would, at one and the same time, exhibit structure at two characteristic lengths, that of the nuclei and that of the whole assembly, including the ice. One might speculate that with such a grain it would be possible to explain the optical observations which according to Whittet *et al.*[8] have hitherto required the existence of three distinct grain models. Speculating further, the requirement of large grains, pointed out by Rowan-Robinson[9], might also be met by our type of grain structure.

The above treatment would seem to demonstrate the plausibility of the existence of plum-pudding grains. A quantitative treatment of their growth, structure, size and optical properties remains, however, to be performed. Work on this is currently in progress and will be published elsewhere.

A comparison of acoustic Doppler vertical velocities with direct measurements in the atmospheric boundary layer

THE quantitative evaluation of the intensity of acoustic echoes from the first few hundred metres of the atmospheric boundary layer (in both stable and convective situations) has been the subject of much recent experimental work[1-5]. The acoustic echo, however, contains Doppler information on the vertical air motion and this could prove of great use in the specification of further important boundary layer statistics such as σ_w^2, the variance of the vertical wind speed[6] and ε, the rate of dissipation of turbulent kinetic energy. Beran *et al.*[7] using a sounder in the monostatic mode (transmitter and receiver aerials located together) derived the profile of the vertical wind component using the acoustic Doppler technique. They did not, however, verify that the estimates of the winds were correct, nor did they record the magnitudes of the Doppler shifts in the weak echo regions between the periods of thermal activity. This paper presents a quantitative comparison between acoustic Doppler vertical winds and direct estimates measured at a fixed height in the atmosphere.

The acoustic sounder operates at a frequency of 1,730 Hz transmitting pulses of length 74 ms at a pulse repetition frequency of 0.44 Hz and up to 25 W of acoustic power. The aerial (which is used for both transmission and reception) is a 6 × 6 array of 16.5-cm diameter re-entrant horn loudspeakers. These figures correspond to a height range of 380 m and a range resolution of 12.25 m. The pulse length (and hence the resolution) and the transmitted power can be varied. The receiver gain can be varied up to 155 dB which includes a ramp gain to compensate for the spherical divergence of the acoustic echoes as they are received from the longer ranges[8]. The transmit pulse is used to synchronise a gating system which controls the selection of the signal received from any chosen height for Doppler shift determination. The gating system provides five gates of variable width hence allowing the signal to be analysed at five different heights. A Hewlett–Packard spectrum analyser with an 8553B r.f. section is used to produce the frequency spectrum of the received echo. The oscilloscope display is automatically photographed using a cine camera triggered by the same gating circuit. The photographed power spectra can be analysed subsequently to determine the frequency shift by use of an expression for the radial velocity v of a scattering eddy given by Beran *et al.*[7]

$$v=\frac{C}{2}\left(\frac{f_0}{f_d}-1\right)$$

for relatively low velocities of up to 2 m s^{-1}. Here f_0 is the transmitted carrier frequency and f_d is the frequency of the scattered signal.

Direct estimates of the vertical velocity were made using a 'reduced' version of the turbulence probe described by Readings and Butler[9]. Basically this instrument consists of a set of sensors mounted on a vane which keeps them facing into wind. The vane is attached to the tethering cable of a large kite balloon (~ 1,300 m^3 volume) and is free to move in the horizontal plane. In this particular application the sensors consisted of a hot wire (double 'V' shaped) inclinometer mounted on a damped pendulum at the front of the vane and a multislot photoelectric anemometer fitted with a 6-cup polystyrene rotor. These sensors record the inclination (ϕ) of the wind vector to the local horizontal (as seen by the sensor) and the total wind speed, V. Thus the instrumentation does not precisely measure the absolute magnitude of the vertical velocity but rather its variability about some chosen mean. The mean value is set by assuming that the average inclination of the flow is zero, $\bar{\bar{\phi}}=0$, where the double bar represents the complete period of a run (typically ~ 1 h). Average vertical velocities ($\bar{w}$) over time periods corresponding to fifty sounder pulses are then obtained from the relationship

$$\bar{w}=\overline{V\sin(\phi-\bar{\bar{\phi}})}$$

Several experiments have recently been carried out to determine the overall accuracy of the balloon-borne turbulence instrumentation including the sensitivity of the observations to sensor design, frequency response, data reduction techniques and the influence of probe motion as it sways with the balloon cable (see Readings and Butler[9], Haugen *et al.*[10]). The results show that the tolerance on the vertical velocity estimates is ~5% and that this wind component is negligibly affected by balloon cable movement.

The results described concern four experiments carried out in convective conditions and two in stable conditions. Figure 1*a* shows the facsimile recording for one of the runs in convective conditions on June 18, 1975. The sequence of thermal activity is clearly shown. During this run the turbulence probe, providing the direct measurements, was located at a height of 70 m. Figure 1*b* shows the comparison between vertical velocities as recorded by the sounder and the probe, the latter being averaged over a time interval corresponding to twenty sounder pulses that is, 46 s, which for the wind speed present during this run is equivalent to a spatial scale of ~ 200 m. This distance is much greater than the separation of probe and sounder scattering volume (80 m). Sufficient signal was still received during periods of weak echo to record a Doppler shift, provided the gain of the receiver was sufficiently high. For both convective and stable conditions the received signal was too weak to permit the recording of the Doppler spectrum on ~ 5% of the total number of occasions. Comparison of Fig. 1*a* and *b* shows that there is little apparent connection between the intensity of the echo (C_T^2) and the updraughts as seen by both sounder and turbulence probes. Beran *et al.*[7] have, however, observed that areas of maximum C_T^2 were associated with regions of maximum vertical wind shear. This is of importance in the qualitative interpretation of acoustic sounder facsimile records and merits further study.

Figure 2 shows a plot of vertical velocity estimates from the acoustic Doppler measurements averaged over fifty pulses against direct measurements over a corresponding time interval using data from all four runs in convective conditions. The data are seen to scatter fairly well about a line of unit slope. A best fit line through the data has slope 0.75 and intercept 0.2 m s^{-1} on the sounder axis. It is not clear to what extent the scatter in this plot is produced by real spatial differences in the vertical velocity field or by the inherent errors in the technique. It should be emphasised that the probe provides a continuous estimate of the vertical velocity at one point only whereas the sounder estimates refer to a discrete set of observations averaged in height (over a resolution depth) and in the horizontal (over the beam area). The values of the correlation coefficients for unstable conditions ranged between 0.7 and 0.9 and the standard deviations of the direct and indirect estimates of vertical velocity were between 0.43 and 0.53 m s^{-1} and 0.4 and 0.6 m s^{-1} respectively. Figure 3 shows the facsimile recording and the plot of vertical velocity against time obtained during stable conditions on June 26, 1975. For these conditions the correlation coefficients were 0.7 and 0.9 with direct and indirect standard deviations of 0.06 and 0.04 m s^{-1} and 0.1 and 0.06 m s^{-1} respectively. The variances recorded refer to the frequency band set by the run duration and the averaging period.

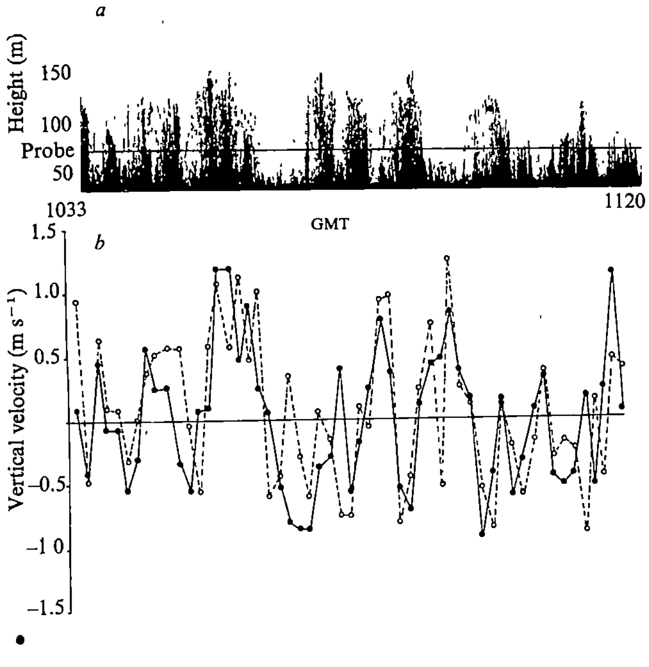

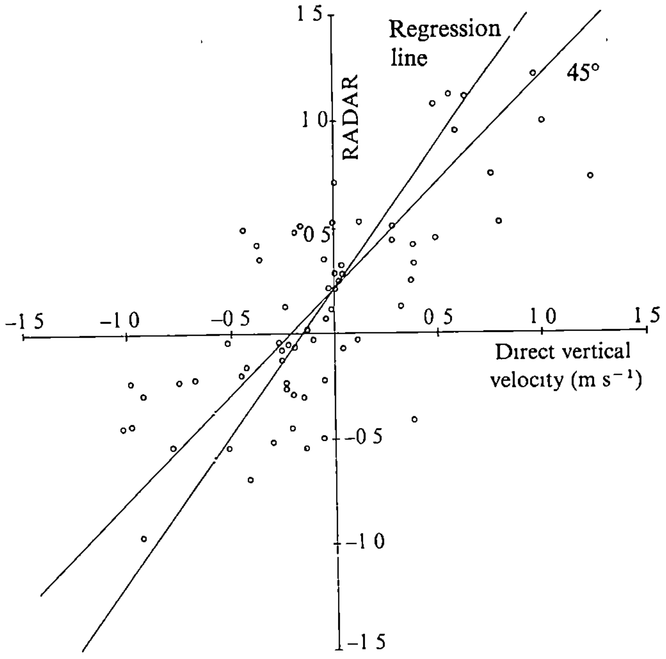

Fig. 2 Plot of vertical velocity estimates from the acoustic Doppler measurements against the direct measurements from all four experiments in convective conditions.

Three sources of error indicated by Spizzichino[11] have been considered in some detail. These are (1) instrumental error; (2) refraction effects and; (3) apparent vertical velocities introduced by horizontal wind components because of the finite beamwidth of the acoustic antenna. The relationship that describes the instrumental error is

$$\sigma_w^2 = \frac{\sqrt{(3)}\lambda^2 b_1^2}{4N\tau_G S_1}$$

where $S_1=((1/\tau_G^2)+b_1^2)^{\frac{1}{2}}$, N is the number of pulses, τ_G is the actual width of the sampling gate and b_1 is the bandwidth of the Doppler signal. For the present results b_1 is ~ 10 Hz, τ_G is 180 ms and N is 50, giving a value for σ_w of 0.12 m s^{-1}, which is reasonably small. For $N=5$, σ_w becomes 0.4 m s^{-1} and in accordance with this the scatter in a plot of direct against sounder estimates was much greater than that in Fig. 2 and such that no discernible trend could be identified. A further source of error is in the determination of the position of the peak of the power spectra, necessary for the measurement of the frequency shift. This error was estimated to be ~ 0.1 m s^{-1} for a single spectral photograph.

The error from refraction can be found if the integrated wind profile to the height of the observation is known. During these experiments this was obtained using the Cardington Balthum[12] and this error turned out to be ~ 0.2 m s^{-1}. This indicates a systematic overestimation of the vertical velocity by the sounder and may be responsible for the positive intercept of the regression line on the sounder axis (see Fig. 2).

The error from the finite antenna beamwidth (~ 10°) is more difficult to assess since it depends on whether the observation time is long enough for the reflectivity being considered to be statistically uniform in the scattering volume. If this is the case then it merely produces spectral broadening and is already included in the instrumental error which involves b_1. If, however, the reflectivity is not uniform and there are many reflectivity maxima within the scattering volume, then the echo spectrum will also exhibit subsidiary maxima. Such

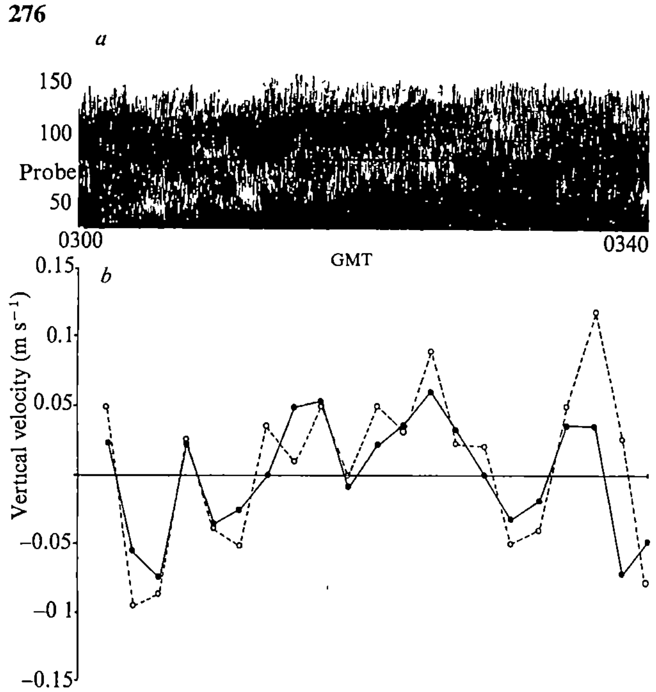

Fig. 3 *a*, Facsimile recording of an inversion between 03.00 and 03.40 on June 26, 1975. *b*, Comparison between sounder estimates (○) and direct measurements (●) of vertical velocities averaged over fifty pulses.

spectra were infrequently observed (~ 2% of the time) and hence for the data presented here this error can be neglected

The results presented above show that reasonable estimates of the vertical wind velocity can be obtained from the returns of a monostatic acoustic sounder operating in both stable and convective atmospheric conditions. The standard deviations of the velocity fluctuations agree well and correlation coefficients between sounder and direct estimates were found to be in the range 0.7–0.9. This technique may offer a quantitative remote method of assessing the mixing quality of the lower atmosphere and could prove of great use in studies of atmospheric diffusion and environmental pollution.

Hercynian high pressure/low metamorphism temperature in the Ile de Groix Blueschists

WE present here an interpretation of K–Ar ages obtained on four glaucophanes, four phengites and one barroisite separated from aluminous, calcareous and basic schists cropping out on the Ile de Groix, off southern Brittany in France. The data include two glaucophane–phengite pairs (PM6 and PC10) and a composite separate specially enriched in barroisite. (Table 1).

Field relations and chemical mineralogy are best known for the glaucophanic eclogite PC10, which occurs in boudins having axes of elongation parallel with the dominant N–S mineral lineation in the south-east of the island. This metabasic boudin lies in a matrix of chloritoid micaschist, and is apparently not an exotic block (the encasing schist has an approximately cofacial paragenesis).

The pressure/temperature conditions during the metamorphism of the PC10 glaucophanic eclogite have been inferred from the Fe/Mg partitioning between adjacent garnet and clinopyroxene rims and from the jadeite content of omphacite in equilibrium with quartz and albite[3] (for analysis of all minerals and rocks except PC10 see refs 1 and 2). This gives an intersection of equilibria at 400 °C and 8K bar pressure, which is consistent with blueschist facies rocks from New Caledonia and Japan, and suggests that metamorphism took place in a region of low geothermal gradient (about 17 °C km^{-1} if average density = 2.9 g cm^{-3})—possibly in a subduction zone.

The concordance of K–Ar dates for two glaucophane–phengite pairs from widely separated aluminous and basic schist outcrops on Groix demands either a simple cooling age or mineral growth age interpretation; there is no evidence in either case for excess ^{40}Ar.

If we assume a maximum prograde growth temperature of 400 °C for the Groix phengites and glaucophanes in equilibrium, it is very likely that they grew at or beneath their blocking temperatures for Ar diffusion[4]. Thus, the age recorded would be the peak of high pressure/low temperature metamorphism rather than the cooling age. Even if mineral reactions ceased before the system became closed to Ar diffusion, it seems unlikely, in the context of a downgoing lithospheric slab, that high pressure/low temperature conditions could prevail for any significant interval of time after the peak of metamorphism was reached[5]. So, because of dynamic instability of the geo-

Table 1 Mineral assemblages of whole-rock specimens*

PM6:	Phengite + ferroglaucophane + chloritoid + quartz + sphene + chlorite. Aluminous schist, possibly metatuffaceous sediment, from Pen Men.
LM8:	Phengite + quartz + garnet + chlorite + glaucophane. Aluminous schist Common pelite lithology from Loc Maria.
LH11:	Epidote + glaucophane + quartz + garnet + phengite. 'Calcareous' schist, probably from margin of metabasic body, near Loc Maria.
LH13:	Epidote +, garnet + quartz + glaucophane + phengite. 'Calcareous' schist, probably basic metatuff from margin of metabasic body near Loc Maria.
PC10:	Garnet + glaucophane/barroisite + omphacite + epidote + phengite + albite + quartz + sphene. Basic schist from core of boudin, Pointe des Chats.

*Listed in order of decreasing modal abundance; dated mineral separates underlined.

*$\lambda_c = 0.585 \times 10^{-10}$ yr^{-1}; $\lambda_\beta = 4.72 \times 10^{-10}$ yr^{-1}; ^{40}K/K = 1.19×10^{-4} atom/atom.

†The 1σ precision of the age determinations for PM-6 glaucophane and LH-11 glaucophane (with ^{40}Ar rad < 10%) has been evaluated at 10%.

‡Barroisite rims are the main impurity. Microprobe gives barroisite rims K_2O = 0.24%, glaucophane core K_2O = 0.04%.

^{40}Ar was determined by isotope dilution mass spectrometry at the University of Naples, using a GD-150 Varian Mat mass spectrometer and the ^{38}Ar-enriched Zurich spike. The calibration was checked by LP-6 USGS standard, a muscovite internal standard (MCT) and Bern LP-6 biotite. K was determined in duplicate by flame atomic absorption with a Perkin Elmer 306 by the method of standard additions. Errors are maximum deviations from the mean. The errors (1σ) for K–Ar dates have been evaluated using the Cox and Dalrymple formula[9].

thermal gradient in an area of blueschist formation, the minerals grew quickly and were uplifted soon afterwards. Thus, the growth age of minerals from such an environment would be indistinguishable within error from the cooling age, given reasonable estimates of uplift rate (see Table 2).

A high pressure/low temperature metamorphic event 335±20 Myr ago on Groix would postdate the intrusion of anatectic granites on the mainland by about 40 Myr (ref. 6), but would coincide with the intrusion of early Variscan granites throughout Brittany 340 Myr BP (ref. 7). This juxtaposition of blueschist with a region of active plutonism from 380 to 340 Myr BP is similar to that observed in the Mesozoic and Tertiary paired metamorphic belts of Japan and California. In the case of Groix, however, no 'median' tectonic line or suture is exposed, the blueschist 'belt' is restricted to one island, and the level of erosion of the 'hot belt' is so deep that the volcanic arc has been stripped off, revealing the underlying batholiths and migmatites.

As soon as subduction of the blueschists had ended, uplift was probably brought about by isostatic response to rapid erosion of the volcanic arc and cordillera to the north. Thermal relaxation to a more normal geothermal gradient after subduction would have produced a rise in temperature during off-loading, and a consequent retrogression of the blueschist facies minerals. If the uplift rate were fast enough, however, the blueschists of Groix would have reached the Earth's surface before the thermal relaxation 'wave' could erase much of the blueschist assemblage.

The barroisites seem to have grown at the expense of glaucophane, omphacite and garnet during a late rise in temperature that did not exceed the Ar-blocking temperature of glaucophane—otherwise the glaucophane ages would all be reset at 294 Myr BP. This would account for the fact that the barroisite overgrowths on glaucophane are significantly younger by about 40 Myr than the high pressure/low temperature metamorphic assemblage. Furthermore, the apparent slight discordance between the ages of PC10 phengite and glaucophane can be explained by the influence of younger, K-rich barroisite rims in the impure PC10 glaucophane separates. The age of this late retrogression (294 Myr BP) corresponds well with uplift and cooling ages throughout the Hercynides, and is synchronous with the intrusion of younger Variscan granites[7], a major break in sedimentation and the main phase of Hercynian folding (Sudetic phase: Westphalian in age).

The Hercynian age proposed for the blueschist metamorphism on Groix is at variance with previous structural interpretations that have related early isoclinal fold phases to the Cadomian Orogeny (690–570 Myr BP)[8]. The basic glaucophane schist assemblages have been considered to have developed from pre-existing, possibly Cadomian, eclogites[1]. By contrast, we consider it very likely that both fold structures and metamorphic assemblages on Groix are Hercynian in age, and that the original lavas and sediments need be no older than 400–500 Myr (unpublished Sr isotope data, M. S. N. C. and P. N. Taylor).

We thank Pam Shreeve of the Oxford Geology Department for her K_2O determinations. Professor Howie of King's College, University of London allowed us to use Z. Makanjuola's mineral separates.

'Space' charging of insulators

THE charging of satellite surfaces by space radiation often results in electrical discharges. These can interfere seriously with electrical systems on board[1]. The surface potentials may vary according to the differing charging properties of dissimilar materials, local changes in capacitance or differences in the radiation environment. Investigations of radiation-induced electron emission have been directed predominantly at metallic or semiconducting materials, and there is a paucity of data on the charging of dielectrics. The work reported here considers

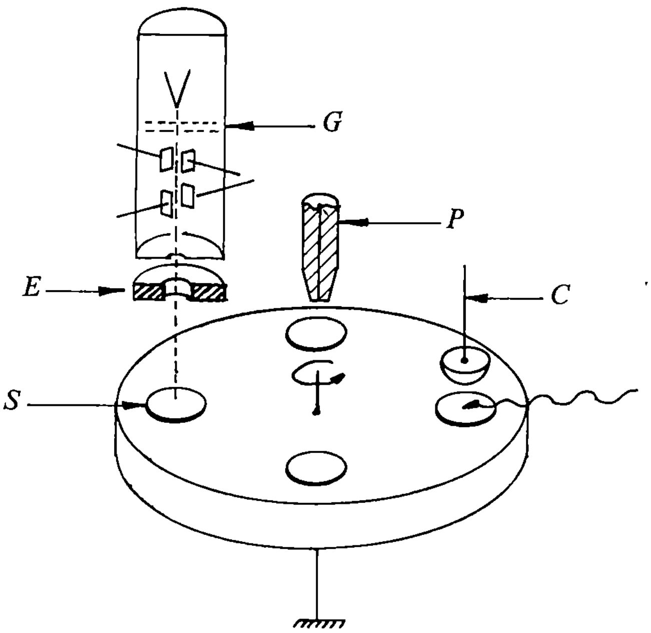

Fig. 1 Schematic diagram of experiment showing the specimen, *S*, mounted on the earthed, rotatable table; the counter electrode, *C*; an electron gun, *G*, with associated electrode; *E*; and the charge measuring probe, *P*.

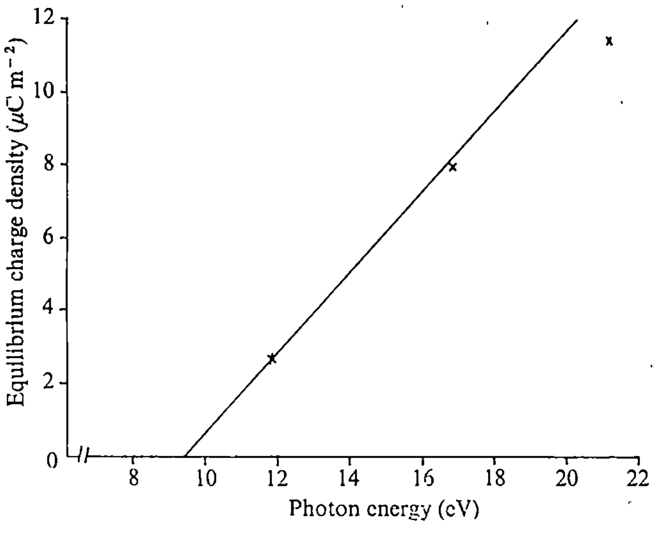
photon-induced charging. Electron-induced charging is considered in ref. 2.

Photoelectric emission from fused silica on irradiation with ultraviolet light has been examined *in vacuo* ~ 10^{-5} mmHg. A schematic diagram of the experiment is shown in Fig. 1. Resonance radiation from, successively, a helium (21.2 eV), neon (16.85 eV) and argon (11.83 eV), discharge is directed, through a monochromator, obliquely on to dielectric specimens mounted on an earthed, rotatable table. The specimens are irradiated when positioned beneath the counter electrode, the charge being subsequently determined by scanning the specimens beneath a probe (see ref. 3).

The equilibrium charge densities produced on specimens of SiO_2, 300 μm thick, have been measured for several extracting (positive) counter electrode potentials. Figure 2 shows the charge densities determined for zero extracting potential plotted against the incident photon energy. The line shown indicates the geometric capacitance of the specimens. The saturation charge density would be expected to follow the photon energy linearly, the retarding surface potential at equilibrium being just sufficient to overcome the photoelectron emission energy, thus inhibiting emission. As evidenced, there is a tendency for the higher charge densities to be less than those predicted, and this may indicate a process of photoconductive loss.

Fig. 2 Equilibrium charge density measured on the SiO_2 specimens plotted against the incident photon energy. The line shows the specimen capacitance.



Positive potentials applied to the counter electrode increase the equilibrium charge density (Fig. 3). Data for all of the wavelengths used are presented, again with the line showing the specimen capacitance. Evidently, the equilibrium charge density is well described by

$$\sigma = \varepsilon\varepsilon_0(h\nu - \varphi_p + V_a)/d\,,\ \mathrm{C\ m^{-2}}$$

where, ε, d and φ_p, are the specimen permittivity, thickness and photoelectric threshold energy, respectively; $h\nu$ is the incident photon energy, and V_a is the counter electrode potential.

The temporal growth of charge has been examined, the emission current being found to decrease monotonically as the surface retarding potential increases. The mode of current decay with an applied extracting field seems different from that for zero potential, suggesting that penetration of the field into the dielectric may affect the excitation process as well as increase the probability of escape of the photoelectron. These investigations will be described more fully elsewhere.

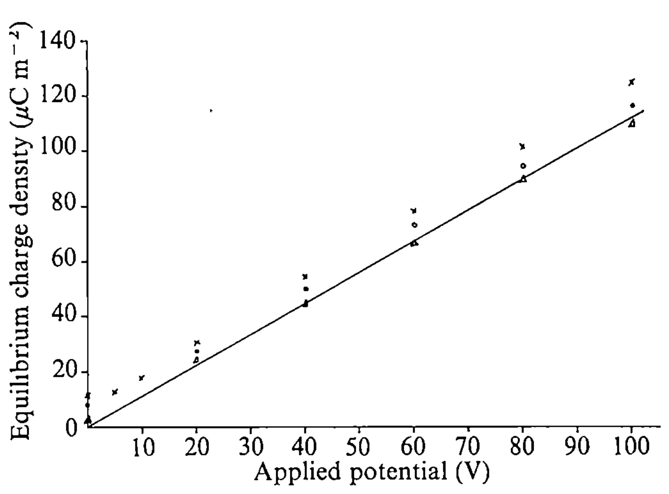


Fig. 3 Equilbrium charge density against applied counter electrode potential, for 21.2eV(×), 16.9eV(○) and 11.83eV(△) incident radiation. Specimen capacitance shown by solid line.

These experiments have shown that photocharging by solar radiation, which is often discounted[4], may not after all be insignificant, particularly in view of the extensive range of photon energies observed in the solar spectrum[5]. Also, it is evident that the equilibrium charges on insulators in space may be highly influenced by local electric fields.

Charges and vacuum flashover

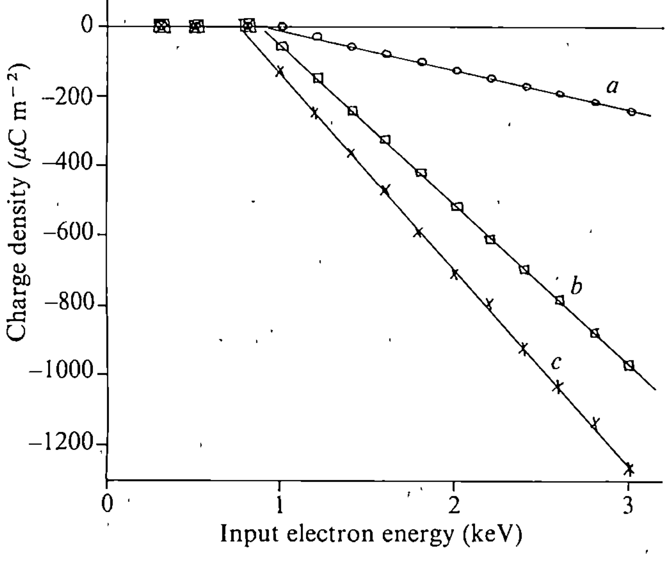
THE increasing importance of vacuum insulation in technology[1] and the recognition of the disruptive effects of surface discharges on satellites in space[2] both impart fresh impetus to the understanding of the flashover effect. Solid insulators are certainly a source of gas *in vacuo*, particularly under bombardment, and can also cause local enhancement of electric stress through the acquisition of surface charges.

de Tourreil and Srivastava[3], among others, have measured positive charges on insulators at stresses well below those necessary for flashover. They proposed a charging process based on secondary electron emission following bombardment of the dielectric by electrons initially field-emitted from the cathode. A secondary emission coefficient, δ, greater than unity (more out than in) obtains for most dielectrics[4] but strictly between well defined limits of input electron energies, that is, $\sim 1\,\text{eV} < E <$ a few keV, for instance. Outside these limits the insulator would charge negatively. Moreover, the emission energy of the secondary electrons is quite small, ~ few eV (ref. 5), and so very little positive charge on the insulator would preclude further emission. These effects are clearly illustrated by the simple experiment, shown schematically in Fig. 1 of ref. 6, in which electrons, with energies of up to 3 keV, are directed through a counter electrode on to insulator specimens, and the charges produced measured.

Specimens of fused silica (300 μm thick) and of two polymers—polycarbonate (55 μm) and polyimide (50 μm)—have been investigated. Figure 1 presents the measured charge densities for zero extracting field plotted as a function of the input beam energy. The upper secondary emission threshold energy (E_2) of the primary electrons is clearly displayed. For higher input energies, the insulator charges negatively, thereby slowing incoming electrons which thus arrive at the surface with precisely the threshold energy, so that equilibrium is attained ($\delta=1$). The full lines agree with the calculated geometric capacitance of the specimens to within 5%.

The occurrence of this dynamic process, rather than of complete repulsion of a high energy, primary beam (the other stable condition) is important since it indicates continued interaction even in the highly charged equilibrium state. Local discharges would probably dissipate larger areas of charge, for example, because of the increased surface conductivity.

Fig. 1 Charge densities measured on SiO_2 (*a*), polycarbonate, (*b*), and polyimide (*c*), specimens, plotted against input electron energy.



For input energies below the threshold (E_2) very little (virtually random) charge is detected on the dielectrics. If an extracting field is generated, however, by applying positive potentials to the counter electrode, positive charge densities are observed, these being independent of the primary beam energy but linearly dependent on the extracting potential. Above the threshold the extracting potential has no effect.

These observations suggest that the straightforward secondary emission theory of insulator charging, leading subsequently to breakdown, may be inadequate. The electric stress at flashover is usually greater than around 5 MV m^{-1}, so the maximum free path for primary electrons in this field, if they are to collide with the insulator surface with energy less than the upper threshold energy, ~ 1 keV, is less than 0.2 mm. Thus, for insulators of greater length, such primary electrons must originate from adjacent sites on the dielectric surface itself. That may be possible; but what happens to the electrons with greater than the threshold energy, that is, those originating further than 0.2 mm from the point of collision? They would charge the insulator negatively, irrespective of any apparent extracting field, except, perhaps, in three possible conditions:

- At low (near grazing) angles of incidence the considerably reduced normal depth of penetration of the primary beam may result in the emission of secondaries, even at high primary beam energies, that is, the secondary threshold energy may be greatly increased.
- The enhanced conductivity of the irradiated surface layers of the insulator may have an important role in establishing local potential gradients.
- The collision of particles originating from both the electrode and the dielectric surfaces may have an important independent role in charging the insulator surface.

To my knowledge these aspects have not been investigated.

Aspartic acid racemisation in dentine as a measure of ageing

THE L-amino acids initially present in bone protein undergo slow racemisation over geological time at a rate which is proportional to temperature[1,2]. We have shown[3] that at the human body temperature of ~37 °C aspartyl residues in tooth enamel protein also undergo racemisation at a rate which corresponds to an enrichment in the D-aspartic acid content of ~0.1% per year. No D-aspartic acid increase was detected in haemoglobin, a protein with a more rapid turnover. We concluded that D-aspartyl residues accumulate in the metabolically stable protein in tooth enamel during the human lifetime as a result of *in situ* racemisation. We proposed that the irreversible first-order rate equation calculated from the enamel results could be used to deduce the age of any stable protein from a long lived mammal and thus the age of the organism itself. The error among samples from old individuals was large, however, probably because attrition and caries reduce the amount of uncontaminated enamel, and thus tend to limit the usefulness of tooth enamel for age determinations. In this report, we show that tooth dentine is a more suitable material, and the extent of aspartic acid racemisation in this fraction can be used as a reliable indicator of mammalian age.

Measurements of the D/L aspartic acid ratio were carried out on 20 samples of dentinal protein extracted from human teeth whose donors ranged in age from 11 to 75 yr. Teeth were obtained from dentists and cleaned of any soft tissue. The teeth were desiccated, the roots removed, and the crowns ground with a mortar and pestle. Dentine fragments were separated by hand under ultraviolet light, because they fluoresce and enamel does not. The dentine fragments were cleaned by ultrasonication in double-distilled water and dilute HCl. They were then dissolved in 6 N HCl, sealed in tubes, and hydrolysed at 100 °C. Hydrolysis was for 6 h rather than 24 h, in order to minimise the amount of acid-catalysed racemisation. Since aspartic acid is released preferentially[4] and the enantiomers should be equally labile, total hydrolysis of the dentine protein was not necessary. The hydrolysate was dried in a rotary evaporator and desalted on Dowex 50W-X8 cation exchange resin, and the fraction containing aspartic acid isolated and derivatised as described elsewhere[5].

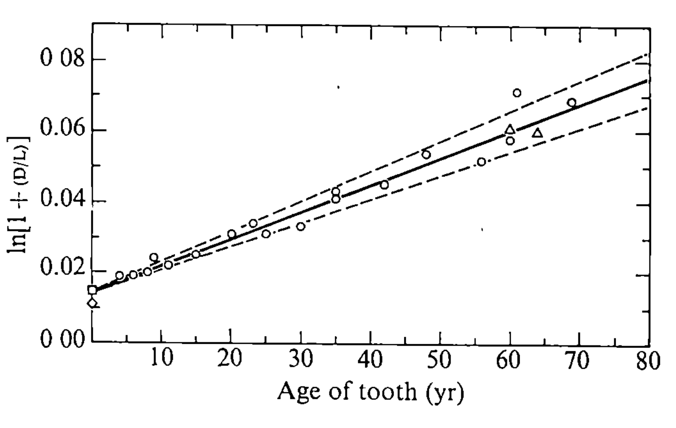
A plot of the dentine data is shown in Fig. 1. The least squares fit of the points can be expressed by the equation

$$\ln[1 + (\textsc{d}/\textsc{l})] = 7.87(\pm 0.39) \times 10^{-4}\,\mathrm{yr}^{-1} t_{\mathrm{d}} + 0.014 \qquad (1)$$

where t_d is the age of the dentine in years. The correlation coefficient, $r = 0.979$, indicates that 96% of the variation in the D/L ratio is accounted for by the age of the tooth. The standard deviation for the dentine results is ±0.0034. The close agreement between the two 35-yr-old teeth, extracted from two different individuals, illustrates the reproducibility of the analyses.

The first-order rate constant k_{asp} for aspartic acid racemisation for dentine (the slope of the line in Fig. 1) falls within one standard deviation of the value for enamel. This indicates that the bulk of dentinal protein is not turned over, although the odontoblasts lining the pulp cavity remain viable throughout life and may deposit secondary dentine as a response to heavy wear[6]. The primary protein in enamel is non-collagenous, but 90% of the organic matrix in dentine is composed of collagen, and there is a phosphoprotein component which may account for 20% of the aspartic acid content of human dentine. Thus, we probably have three examples of metabolically inert polypeptides in which the aspartyl residues show increasing racemisation with increasing age. Moreover, collagen comprises 25–30% of the protein in the human body, and it is distributed as connective tissue throughout every organ system. This study shows that ~6% of the L-aspartyl residues in metabolically stable protein will have racemised to the D-enantiomers by 60 yr of age. It seems reasonable to assume that some of the physicochemical properties of the molecules will be altered as a result of this small amount of racemisation, and the effects should become more significant with increasing age. If a similar racemisation process occurs in all metabolically inactive proteins, then it may be part of the complex ageing changes which take place in mammals.

Fig. 1 Plot of ln[1+(D/L)] for aspartic acid against age of the dentine in years (solid line). Actual ages of tooth donors are corrected, depending on the type of tooth, by the values listed in ref 3. The slope (7 87×10⁻⁴ yr⁻¹) of the dentine line is equal to k_{asp} for tooth dentine at approximately 37 °C. The broken lines represent the k_{asp} values calculated for a ±0.7 °C difference in body temperature. ○, Individual of known age; △, exact ages unknown but estimated by dentists (these points were not used to calculate the least squares fit); ◇, albumin; □, bovine tendon collagen.



These results also indicate that dentine can be used, in the same manner as enamel, for estimating the age of a mammalian tooth. In many respects, racemisation analyses of dentine should be more reliable. First, dentine accounts for a much greater proportion by weight of a tooth than does enamel. In addition, the percentage composition of protein in dentine is 100 times that in enamel[8]. Thus, the chances of contaminating a sample are significantly reduced when dentine is analysed. Enamel is subject to surface alterations (attrition, bacteria, caries) which could affect its amino acid composition, whereas dentine is relatively sheltered by the enamel layer. Among people experiencing heavy tooth attrition, to the extent that very little of the crown remains after 40–50 yr, root dentine could be analysed.

The analytical advantages of dentine over enamel are reflected by the correlation coefficients. Since the total error is $(1-r^2)100$, all sources of error (experimental and contamination) amount to 4% in the dentine results, as compared with 15% for enamel. The standard deviation of the enamel values is more than twice that of the dentine values.

It is interesting that the enamel samples older than 50 yr had a standard deviation 2.4 times that of younger samples[3]. Although there are only four dentine samples of known age above 50 yr, a similar age-related increase in the scatter occurs with the dentine values. The standard deviation for dentine analyses of teeth greater than 50 yr old is 0.0060, compared with 0.0021 for teeth less than that age. Temperature is one factor which could cause small differences in the rate of racemisation between individuals. Human body temperature averages 36.9 °C and has a range of ±0.7 °C (ref. 9). This temperature variation would result in a change of about ±12% in the value of k_{asp} (an activation energy of 33 kcalorie mol⁻¹ was used in this calculation[10]). The broken lines in Fig. 1 represent the estimated k_{asp} values at 37.6 °C and at 36.2 °C. It can be seen that changes in the rate constant produce greater deviations among older tooth samples than among younger ones. Two standard deviations (±2σ) of the experimental k_{asp} for dentine fall within the range of the k_{asp} values calculated for a ±0.7 °C difference in body temperature. Thus, the 2–3 times increase in the standard deviation among dentine and enamel samples greater than 50 yr old could be due to differences in body temperature among the individuals.

The racemisation ageing method can now be used to test claims of unusual longevity among the populations of Georgia in the USSR, Hunza, and Vilcabamba, Ecuador. Given a tooth suitable for analysis, an age estimate will fall within ±10% of the individual's actual age (approximately ±2σ of the dentine distribution), and body temperature information will further reduce the error. We would appreciate the cooperation of gerontologists and dentists in obtaining tooth samples from these or other very old people.

Sun and shade differences in productivity of reef corals

REEF CORALS are mutualistic symbiotic associations between cnidarians and dinoflagellates. The algae photosynthesise and translocate photosynthate to the animal partner, although the animal is capable of heterotrophic nutrition[1–5]. Some reef corals have wide bathymetric ranges[6,7] and the growth and survival of individuals in the deeper regions of the euphotic zone could result from an increase in the energy efficiency of the symbiotic complex. A number of reports document the laboratory-determined photosynthesis–radiation responses of corals[8–12] and zooxanthellae[13], but because the details of the habitat or depth from which the animals were collected are rarely described, comparisons among results in the literature are difficult. Here we provide evidence for the existence of 'sun' (heliophytic) and 'shade' (sciophytic) differences in the net photosynthesis–radiant flux intensity response of individuals of one coral species from 10 and 25 m depth on the same reef in an atoll lagoon.

Individuals of the foliaceous coral *Pavona praetorta* Dana were collected underwater at the Marine Pier Pinnacle Reef 300 m west of Enewetak Island (site Fred), Enewetak Atoll, Marshall Islands. Immediately after collection, the specimens were placed at the same depth in 1.5-l Perspex containers in which net rates of photosynthesis were determined (Fig. 1). Oxygen production per unit chlorophyll *a* was measured for 5-min intervals as a function of radiant flux intensity, and the data were fitted to the Michaelis–Menten equation by an iterative maximum likelihood solution method, which improves on an initial Lineweaver–Burk estimate[14,15].

The best fit Michaelis–Menten curves for the *Pavona* specimens are plotted in Fig. 1 with 99% confidence limits (one-tailed Student's t test, $n-2$ d.f.) for P_{max} (maximum photosynthetic rate) and K_m (radiant flux intensity at half saturation). By analogy to enzyme kinetics, K_m is a measure of the affinity of the photosynthetic system for radiant energy. The lack of overlap of the confidence limits indicates that the K_m for the 25-m specimens are lower than the value for the 10-m specimen (Table 1). Therefore, relative to their maximum photosynthetic rates, the deep water individuals saturate their photosynthetic machinery at lower radiation intensities than the shallow water individual. This is analogous to the 'sun' and 'shade' differences documented for canopy and understory plants[16] and for phytoplankton acclimatised to high and low light intensities[17,18]. The saturation of deep water individuals at lower radiation intensities is consistent with Margalef's[19] observation of greater A_{450} of pigments from deep water corals compared with conspecifics from shallow water. The measured difference in photosynthetic response is not likely to be due to spectral quality changes in the light between 10 and 25 m, because the 640–670-nm light which affects the red action spectrum peak of photosynthesis[13] amounts to only 2% of the total light flux at 18 m and 0.03% at 25 m (ref. 20), a difference below the resolution range of our *in situ* light meter circuit. We found no difference in temperature between study sites, and von Arx[21] has estimated that atoll lagoons have complete water overturn every 150 h, indicating that temperature stratification is unlikely. Therefore we believe that the differences in photosynthetic response between the two study sites are not temperature related.

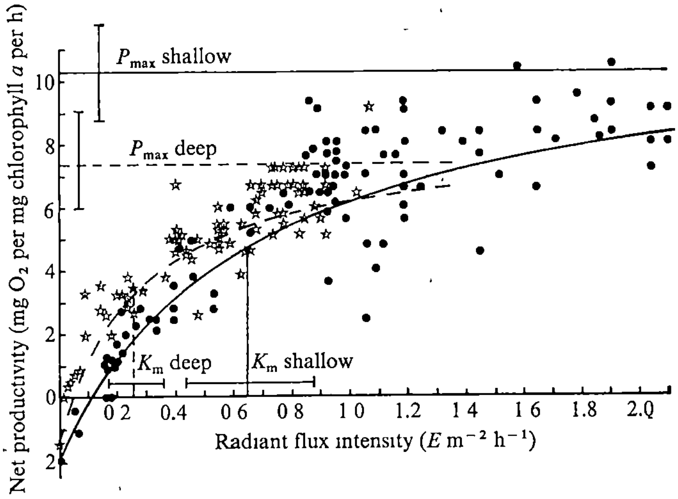

Fig. 1 · Photosynthesis–radiation intensity relationships for *Pavona* from 10 m (●) and 25 m (open star). E, einstein (= 6.02×10^{23} quanta). Ideal curves, maximum photosynthetic rates (P_{max}), radiant flux intensities at half saturation (K_m), and their 99% confidence limits are from maximum-likelihood regression analysis[14,15]. 25-m data are from one of the two replicates. Values at zero radiant flux are means: shallow specimen $x = -1.84$, s.d. = 0.29, $N = 71$; deep specimen $x = -1.41$, s d. = 0.27, $N = 117$ Experiments were run for 26 h *in situ* in Perspex chambers which were stirred continuously and flushed with ambient water at 35-min intervals The instrument design was modified from that of McCloskey[22]. Oxygen concentrations in the chambers were monitored with silver–platinum electrodes[23] and photosynthetically active radiation (400–700 nm) at the depth of the respirometers was measured with a quantum sensor (Lambda Instruments). These values were recorded continuously on strip chart recorders (Esterline Angus Minigraph). The electrodes were calibrated in air-saturated seawater and a yeast suspension in dilute sucrose solution, according to the tables of Green and Carritt[24], and checked with an independently calibrated commercial oxygen meter (Yellow Springs Model 57). The *in situ* light sensor was calibrated with a factory-calibrated quantum radiometer (Lambda Instruments). After termination of the experiments, the corals were frozen. Chlorophyll was extracted in 90% acetone (20 h, dark, 5 °C) Extinctions were measured in 10-mm cells (Beckman Model DU Spectrophotometer), and total chlorophyll *a* was estimated by the trichromatic equations of Richards[25].

Franzisket's[11] data from specimens collected at 3 m indicate K_m values higher than our 25-m specimens and within the range of our 10-m samples, corroborating our interpretation that 'sun' and 'shade' differences exist in the photosynthetic response of corals from high and low light regimes (Table 1). Evidence in support of the phenomenon comes from our *in situ* data for *Plerogyra*, *Porites* and *Acropora* from the Philippines and from Barnes and Taylor's[12] *in vitro* data on *Montastrea annularis* from the Caribbean (Table 1). The 18-m depth specimens have K_m values in the range of our 25-m *Pavona*, the *Montastrea* from 15-m is intermediate between our 25-m and 10-m *Pavona*, and the *Acropora* from 3 m exhibits a K_m in the range of Franzisket's[11] 3-m specimens and our 10-m *Pavona*. The overlap in K_m among the different coral species

Table 1 Half-saturation constants for photosynthesis as fit to the Michaelis–Menten* equation

Species	Depth (m)	K_m (E m^{-2} h^{-1}), Maximum likelihood estimate	One-tailed confidence limits Lower ($P < 0.01$)	Upper
P. praetorta Dana	25	0.26	0.18	0.37
P. praetorta Dana	25	0.14	0.00	0.38
P. praetorta Dana	10	0.63	0.43	0.88
Plerogyra sinuosa Dana	18	0.18	0.10	0.26
Porites lutea Milne Edwards and Haime	18	0.11	0.07	0.15
Acropora cf. *arbuscula* Dana	3	1.23	0.76	1.99
Kaneohe Bay corals, Hawaii† (ref. 11)	3	0.65	0.46	0.86
Montastrea annularis Ellis and Solander[12]	15	0.41	0.21	0.67

Each line represents a 24-h incubation of a single coral.

*Michaelis–Menten equation: $P = (P_{\max} \times I)/(K_m + I)$ or $P_{\text{relative}} = P_{\text{observed}}/P_{\max} = I/(K_m + I)$

†Pooled data from four species: (*Fungia scutaria* Lamarck, *Montipora verrucosa* Lamarck, *Porites compressa* Dana and *Pocillopora meandrina* Verrill); regressions run separately were not significantly different ($P > 0.05$).

suggests that, given a particular light regime, the algal photosynthetic efficiency relative to the maximum photosynthetic rate is independent of the coral species that the algae inhabit. In addition, Kawaguti[8] found the compensation light intensity was related to habitat: individuals from deeper or shaded places showed lower values.

The existence of acclimation to ambient light regime in corals suggests that extrapolation from measurements on individuals at one depth to the behaviour of the population over the whole depth range is not valid. Similarly, the efficiency of translocation of photosynthate from alga to animal partner may vary with depth. *In situ* 24-h measurements on individuals from a range of depths and species are needed to begin to resolve the question of the trophic plasticity of corals as a function of habitat.

D.S.W. is supported by a USNSF Graduate Fellowship. The work at Enewetak was supported by a USERDA grant through the University of Hawaii—Mid-Pacific Marine Laboratory Program to J.W.P. Philippine support came from a USNSF grant through the Scripps Institution of Oceanography RV Alpha Helix Program to J.W.P. R. Trench and K. Porter provided field assistance, and with C. Richardson, D. Titman, D. Heisey, C. S. Yocum, and S. Ohlhorst, aided in discussion of the project. R. Tyler, R. Reed, J. Mite, L. McCloskey, L. Somers and P. Blackburn aided in the design and testing of the instruments.

Frost sensitivity of *Zea mays* increased by application of *Pseudomonas syringae*

DRIED, powdered corn leaves (*Zea mays* L.) dusted on to the leaves of corn seedlings, will increase frost damage to treated seedlings relative to untreated controls at ~ −4 °C (refs 1, 2). In a preliminary attempt to isolate the entity responsible for this activity, we found that water extracts of corn leaf powder from healthy field-grown plants caused as much increase in frost sensitivity when applied as a spray to seedling corn, as did application of the powder itself when tested as described below. Addition of either streptomycin or tetracycline (1,000 p.p.m.) to these water extracts eliminated their activity, suggesting the possible role of bacteria in this effect.

Corn seedlings for frost sensitivity measurements were grown in sterilised vermiculite in a plant growth chamber (day· 18 h, 30 °C; night· 6 h, 20 °C) to the 3-leaf stage. Plants were watered daily with nutrient solution. Ten or more pots (6 plants per 10-cm pot) were used for each treatment. Unless otherwise noted, treatment was given 24 h before freezing and the plants were held in a mist chamber until 20 min before freezing. Immediately before freezing, all pots were positioned randomly in a controlled temperature chamber at ~ 0 °C. The air temperature was lowered at ~ 0.1 °C min^{-1} to −3.0 °C and then at ~ 0.04 °C min^{-1} to −3.5—−4.0 °C. Maximal differences in frost damage between treated and untreated plants occurred in this temperature range. The air temperature in the chamber was then increased at ~ 1.0 °C min^{-1} to 30 °C. Frost damage was assessed by counting the number of leaves per plant with symptoms of frost injury.

Forty-two bacterial isolates of varying colony colour and morphology were obtained by dilution plating from water extracts of corn leaf powder. Each isolate was grown on nutrient agar, suspended in 0.1 M phosphate buffer, *p*H 7.0, sprayed on to corn seedlings and assayed for the ability to increase frost sensitivity of corn at −3.5 to −4.0 °C. Only one of the 42 isolates was active in increasing the frost sensitivity of corn seedlings. When leaves of corn seedlings were sprayed with suspensions of this isolate in buffer 24 h before freezing > 95% of the leaves were damaged at −3.5 to −4.0 °C, whereas < 8% of the leaves of plants sprayed with buffer alone were damaged at this temperature On the basis of its response to standard physiological tests[3,4], this isolate was identified as *Pseudomonas syringae* van Hall, a species that includes strains pathogenic to a large number of diverse host plants including corn[5]. We have not observed pathological symptoms even when corn plants were held without freezing for up to 10 d after inoculation.

For ~ 8 h after application of the bacteria, the frost sensitivity of corn plants did not increase. It increased steadily from ~ 8 h until ~ 24 h (Fig. 1), after which little change occurred for at least 5 d. The amount of frost damage observed in seedling corn plants increased with increased *P. syringae* populations applied[6]. At each time interval shown in Fig. 1, more leaves sprayed with 4×10^6 cells ml^{-1} were damaged than those sprayed with 4×10^5 cells ml^{-1}. As indicated in Fig. 2, suspensions as dilute as 1.5×10^4 cells ml^{-1} caused significant increases in frost sensitivity (75% damage for plants held under mist for 24 h before freezing). Application of higher *P. syringae* populations (~ 10^7 cells ml^{-1} with wet leaves or 10^8 cells ml^{-1} with dry leaves) resulted in frost damage to nearly all leaves; untreated control plants showed damage to fewer than one leaf in 12. Plants held in a mist chamber for 24 h between application of cells and freezing, sustained greater frost damage at all applied cell densities than plants left dry during this period. The increase in frost sensitivity both with moisture and with time suggest that either growth of the bacteria or movement to some favourable site(s) on or in the leaves, or both, are important in enhancing frost sensitivity.

Sixty-four of the 67 tested isolates of *P. syringae* increased the frost sensitivity of corn seedlings. Three of five isolates of the closely related species, *P. coronafaciens*[7] also were active, whereas one isolate each of *P. tabaci, P. glycinea, P. phaseolicola, P. marginalis,* four isolates of *Erwinia stewartii* and one of *Escherichia coli* were not active.

Even plants very sensitive to frost can withstand temperatures slightly below 0 °C (refs 8–11) because of the supercooling of intracellular water. Frost damage to such plants in the field has been reported to occur at ~ −2–−5 °C, presumably by explosive crystallisation of supercooled intracellular water[8]. Similarly, almost all our growth chamber-grown plants with *P. syringae* on their leaves were killed at −4 °C (Fig. 2). Plants lacking leaf surface populations of *P. syringae*, however, were not substantially damaged until the temperature reached was ~ −8.0 °C (Fig. 3). Thus, our *P. syringae*-treated plants seem to be almost equal in frost sensitivity to plants in the field. It is our growth charmber-grown controls, lacking leaf populations of *P. syringae*, that differ substantially from field-grown plants with regard to frost sensitivity.

Although the importance of ice nuclei in initiating ice crystallisation, and thus frost damage, has been recognised[11], the nature and source of these ice nuclei remain unknown. Maki *et al.*[12] have reported that *P. syringae* is active as an ice nucleus at temperatures as warm as −2 to −3 °C. We have found that all 64 isolates of *P. syringae* and all 3 of *P. coronafaciens* which increased frost sensitivity of corn were also active in ice nucleation at −5 °C or above as measured by a modification of the procedure of Vali[13]. All isolates which did not increase the frost sensitivity of corn (including the 41 inactive isolates from water extracts of corn leaf powder) were not active in ice nucleation at

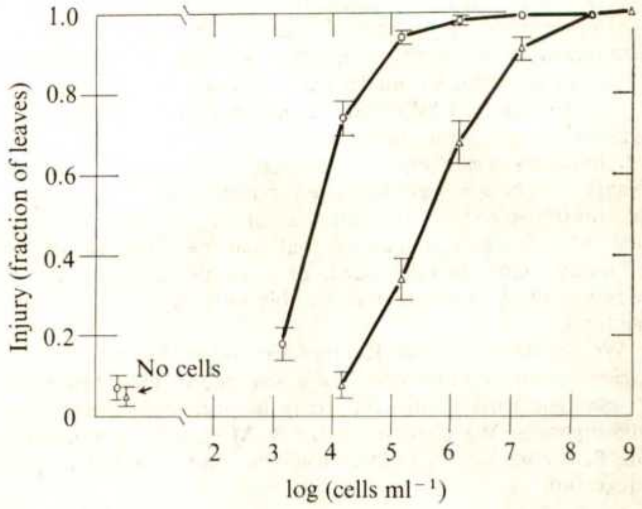

Fig. 2 Effect of applied *P. syringae* populations on frost injury to corn seedlings. Three-leaf-stage corn seedlings were sprayed with cell suspensions in 0.1 M phosphate buffer *p*H 7.0 (0.5 ml per plant) and held in a dark mist chamber at 24 °C (○) or left dry in the dark at 24 °C (△) for 24 h before freezing. The vertical bars represent the s.e.m.

Fig. 1 Effect of the duration of the time between application of *P. syringae* and freezing on frost injury. Three-leaf-stage corn seedlings were sprayed with cell suspensions of 4×10^5(△) or 4×10^6 (○) cells ml^{-1} in 0.1 M phosphate buffer *p*H 7.0 (0.5 ml per plant) and incubated in a mist chamber for the times shown on the abscissa before freezing. The vertical bars represent the s.e.m.

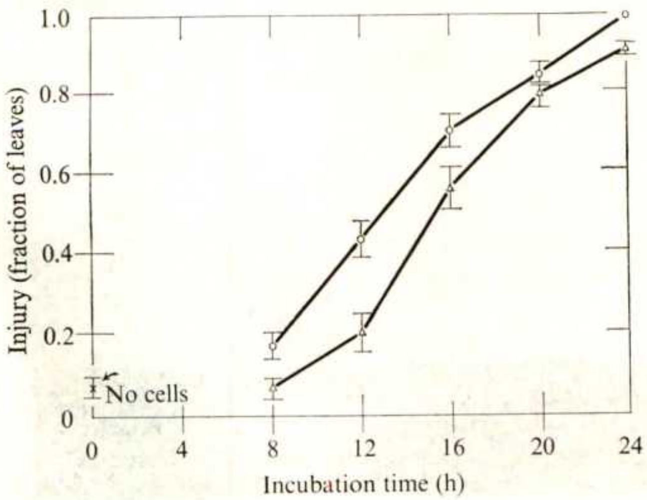

Fig. 3 Frost sensitivity of corn seedlings lacking leaf surface populations of *P. syringae*. Three-leaf-stage corn seedlings were placed in a controlled environmental chamber at 0 °C and were cooled at the rate of ~0.05 °C min^{-1}. Groups of plants were removed from the chamber at temperatures shown on the abscissa and placed in a growth chamber at 30 °C. The vertical bars represent the s.e.m.

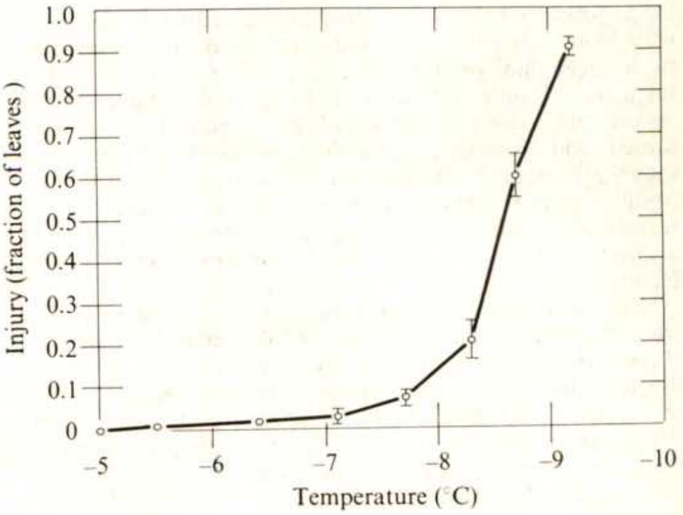

−5 °C. Thus, the decreased frost sensitivity of our untreated control plants may be caused by supercooling to temperatures below those that are possible in the presence of active bacterial ice nuclei (for example, *P. syringae*).

The part played by epiphytic bacteria in promoting frost sensitivity has not been recognised previously. Large epiphytic bacterial populations exist on the leaves of most plants[14–19]. *P. syringae* has been reported as a component of these epiphytic populations on host and non-host plants[16,17,19]. Thus, it may be that 'natural' frost sensitivity of many plants is influenced, or even determined, by the presence of *P. syringae* and possibly certain other epiphytic bacteria.

We thank Dr Arthur Kelman for use of his extensive *P. syringae* culture collection, for assistance in identifying our *P. syringae* isolate, and for many helpful ideas during this investigation. We also thank Dr B. M. Lund for providing the *P. coronafaciens* isolates used here and for her helpful suggestions.

Fog basking by the Namib Desert beetle, *Onymacris unguicularis*

THE Namib Desert along the south-western coast of Africa supports a sand dune fauna without counterpart elsewhere in the world[1]. The trophic base of the arthropod fauna is wind-blown detritus[2]. Aperiodic advective fog collection from vegetation[3] or detritus[4] is a possible source of water for diverse Namib animals. For the specialised fauna living in vegetation-less dunes, fog collection from detritus[4], disturbed sand projections[5], directly from humid air[6], or from water precipitated on the body[4,7], seem to be the only possible water uptake methods. Water uptake from saturated or subsaturated air, demonstrated for a few arthropod species[6], is not a physiological capability of Namib tenebrionids already investigated[4,6,7].

Here we report field observations of direct water uptake from fog precipitated on the body of the tenebrionid beetle, *Onymacris unguicularis*. In early October 1975 we established a study area on sand dunes south of the Kuiseb River at Gobabeb (23°34′S, 15°03′E, elevation 408 m), South West Africa, and continued observations through January 1976. On a series of small linear dunes all *O. unguicularis* were collected and marked with small (diameter 2.5 mm) numbered disks glued to the thorax. The study area, including 5 km of dune ridges, was traversed every afternoon, during the peak activity period of these beetles. We took all beetles collected to the laboratory, weighed them, and returned them to their dunes within 2 h of capture. The beetles either burrowed into dune slipfaces when returned or remained active, feeding on detritus for an hour or more before retiring to subsurface sands. Collections were repeated daily and numbering continued until over 90% of all beetles collected were numbered individuals. Recollection of marked individuals was facilitated in this environment because, in spite of the large spatial dimension of the study area there is no vegetation and these large (13–22 mm) black beetles stand out against the reddish sand substrate.

Ordinarily *O. unguicularis* are diurnal, preferring the warm part of day, and remaining buried in the sand of dune slipfaces overnight. But during nocturnal fogs they emerge and climb the slipface to the crest. There they take a characteristic head-down stance (Fig. 1), facing into the fog-laden wind. Dune slipfaces oriented into the wind also intercept fog. Beetles emerging there adopt the typical head-standing posture where they emerge.

As water collects on these beetles it trickles down the body to the mouth. Actual uptake of water was established by collecting beetles at the end of the head-standing performance, when they burrowed into subsurface sands. They were then taken to the laboratory and allowed to dry for 2 h. All adhering sand grains were removed with a brush and the beetles were weighed. Fog water uptake ranged from an

Fig. 1 *a*, Windward view of *Onymacris unguicularis* in a typical fog-collecting stance. *b*, Another individual at the usual fog-collecting site, the crest of a sand dune. Note the water collected under the head, which is being drunk.

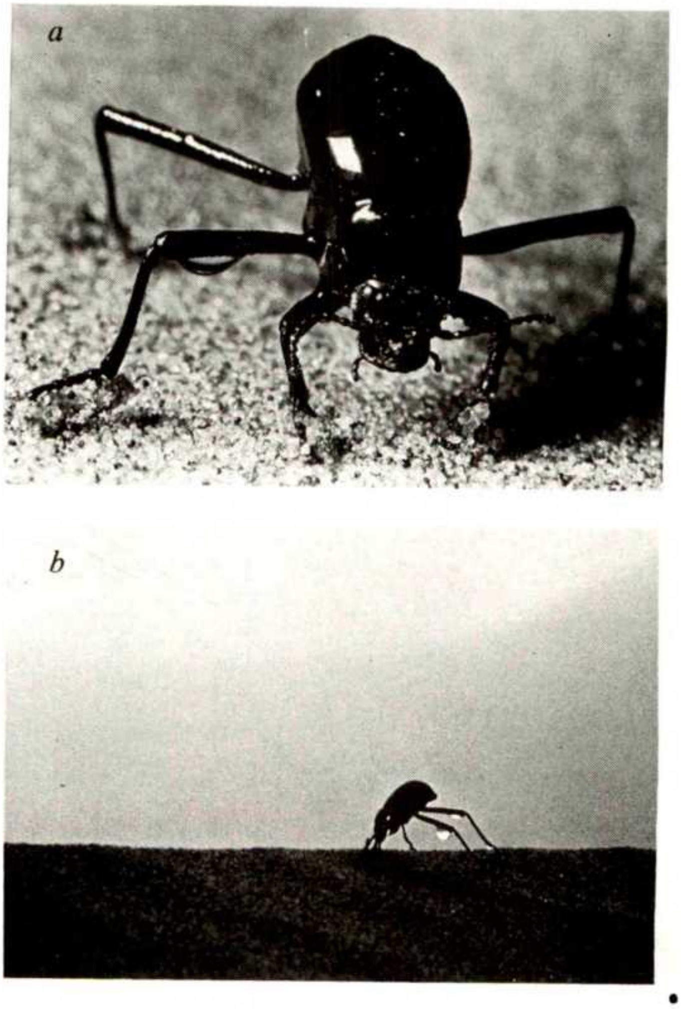

Table 1 Fog water gain expressed as percentage weight change of total body weight following fogs of various strengths on the Namib Desert

Date	Fog (mm)	Weight change (%) Mean	Corrected mean	Minimum	Maximum	*N*
October 14, 1975	0.50	+13.36	+14.50	+3.57	+34.01	24
November 5, 1975	0.35	+ 0.49	+ 1.63	−1.99	+10.48	32
November 25, 1975	0.10	+ 4.33	+ 5.47	−5.76	+16.31	52
November 29, 1975	0.65	+ 7.25	+ 8.39	−2.19	+20.79	33
December 1, 1975	0.10	+ 0.97	+ 2.11	−2.46	+ 4.91	16

The correction factor of 1.14% determined to be the mean overnight weight loss without fog has been added to the mean to provide a corrected mean weight change during fog more closely approximating the actual uptake of fog water but is not applied to the maximum and minimum weight changes.

average of 12% to no gain for various fogs (Table 1). The maximum weight gain by an individual in a single fog was 34% of total body weight before the fog. These values are for beetles captured and weighed the evening before a fog, and recaptured the morning immediately following the fog.

To determine the weight changes from evening weighing to morning weighing in the absence of an intervening fog, a control sample of beetles was weighed, marked and placed on a dune in the evening, then recaptured the following fog-less morning. Of 48 such recaptures all but three individuals lost weight ($\bar{x}$ change −1.14%, range −3.00% to +0.72%). Thus any mean weight increase by a population of beetles overnight during a fog can be assigned to uptake of fog water.

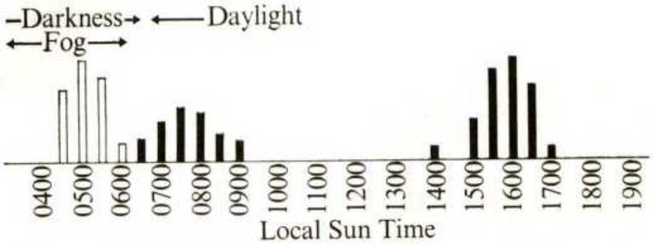

Fig. 2 The timing of activity by *O. unguicularis* on November 12, 1975. The open colums represent individuals holding the fog-collecting posture. The dark colums are individuals actively engaged in other activities. The maximum number of active individuals at any time was 45 on this date.

Fog basking by *O. unguicularis* occurs at times when they are not ordinarily active (Fig. 2). They may emerge any time during the night that wet fogs occur. Their usual foraging periods occur during the morning and late afternoon, coinciding in the afternoon with the strongest winds which transport the detritus on which they feed.

Onymacris unguicularis is active throughout the year and thus encounters variable intervals between fogs. Fogs as light as 0.1 mm on the Gobabeb fog screen elicited fog basking.

Another group of Namib dune tenebrionid beetles, genus *Lepidochora*, living near Gobabeb build ridges in the sand to catch water[5] and we have observed spiders, lepismids and other tenebrionids active on foggy mornings. Direct collection of fog water seems to be important in the water economy of some Namib Desert animals, and to involve in certain cases highly developed methods.

We thank Drs E. B. Edney and M. D. Robinson for valuable comments. This study was supported by the CSIR and Transvaal Museum (M.K.S.) and the National Science Foundation (W.J.H.). The permission to conduct this study from the Nature Conservation Department, South West Africa, is gratefully acknowledged.

Nucleating agents in the haemolymph of insects tolerant to freezing

MANY insects that survive the winter in cold, exposed habitats in arctic or temperate regions are sensitive to freezing. These insects usually have supercooling points below −15 °C, and their capacity for supercooling has been shown to increase considerably with increasing concentrations of glycerol in their body fluid[1]. On the other hand, adult insects that are tolerant to freezing ('freeze tolerant') seem to freeze invariably at high subzero temperatures (from −6 to −10 °C), without regard to the concentration of glycerol and other polyols in their body fluid[2–4]. We report here that haemolymph from freeze-tolerant adult beetles contains a substance, which induces freezing in the haemolymph at about −6.5 °C. Haemolymph from freeze-sensitive species seems to lack this substance. Such substances probably constitute the physical basis of the remarkably high supercooling points of freeze-tolerant adult insects.

During the winter of 1975 we found that several species of tenebrionid beetle, inhabiting the mountain areas of southern California, were tolerant to freezing. These beetles had supercooling points from −5.5 to − 7.0 °C, whereas freeze-sensitive beetles froze at temperatures from −12 to −20 °C. Preliminary experiments showed that 5-μl samples of isolated haemolymph from freeze-tolerant (*Eleodes blanchardi* Blaisd.) and freeze-sensitive (*Iphthimus laevissimus* Csy.) tenebrionids froze within the same temperature range as did the respective intact beetles. Mixtures of haemolymph from the two species, however, also froze within the range of the intact freeze-tolerant beetles, even when the haemolymph of this species constituted as little as 5% of the volume of the mixture. These observations indicate that haemolymph from freeze-tolerant *E. blanchardi* contains nucleating agents, which induce freezing at a few degrees below zero, and which probably cause the low supercooling capacity of these beetles. Similar nucleating agents might be the cause of the high supercooling points reported for other freeze-tolerant beetles.

If freezing at high subzero temperatures is physiologically important to freeze-tolerant insects, they would be expected to contain nucleating agents, except in cases where freezing, as described by Salt[5], is initiated by inoculation. To investigate the distribution of nucleating agents, we took

Beetles of the genus *Coelocnemis* are classified according to Doyen[6].

M and C, beetles collected in the mountains and on the coast in southern California, respectively; N, beetles collected in Norway; S and W, beetles collected in summer and winter, respectively.

*Mean ± s.d. of n beetles.

†Mean ± s.d. of m parallel 5-μl samples of NaCl solution, containing about 5% of haemolymph obtained from n beetles. Samples of NaCl solution were kept inside thin glass capillaries, and the haemolymph was added by means of a microsyringe. Supercooling points were determined by cooling at a rate of 20 °C h^{-1}, while the temperature was measured by means of a copper–constantan thermocouple. Supercooling points were indicated by a sudden increase in temperature, due to the release of heat of fusion of water.

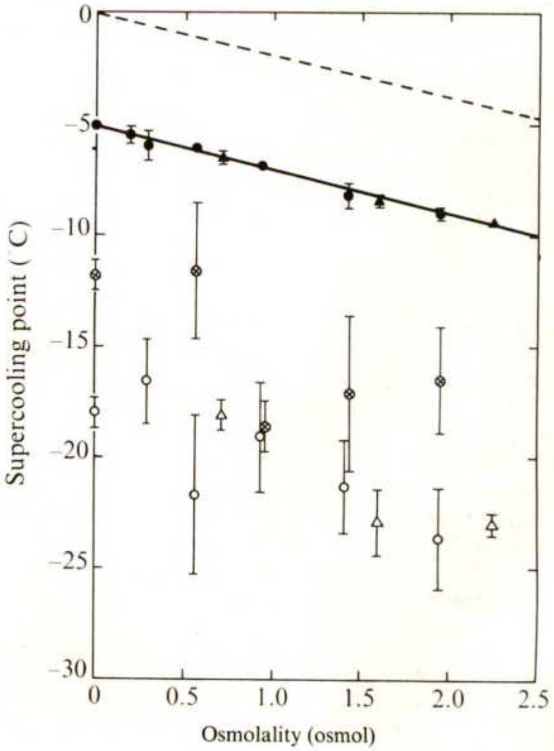
samples of haemolymph from several species of beetles representing different kinds of water survival, and examined their effect on the supercooling points of samples of 0.9% solution of NaCl. The survey included both freeze-tolerant and freeze-sensitive species, which were collected in the mountains of southern California and around Oslo. We also included beetles collected on the coast near San Diego, where they are probably never exposed to subzero temperatures. Beetles were collected in summer and winter and kept in the laboratory at +4 °C and +20 °C, respectively, for up to 1 month. They were fed on dry oak leaves and pieces of apple, but starved for 1–2 d before being used, to prevent possible nucleators in the gut contents from influencing the supercooling points of the intact beetles. To judge whether beetles were freeze tolerant or not, we cooled them at a rate of about 20 °C h^{-1} until they froze spontaneously. When the temperature of a freezing beetle had returned to its supercooling point, it was thawed slowly. To be classified as freeze tolerant, the beetles had to behave in an apparently normal way during the following 2 d, while kept at room temperature. The beetles here classified as freeze sensitive all looked dead after thawing, and they did not recover during the period of observation.

The results in Table 1 show that haemolymph from all freeze-tolerant beetles induced freezing in the NaCl solutions at temperatures of −5.4–−6.9 °C. During summer these beetles became sensitive to freezing, and at this time the freezing-inducing effect of their haemolymph was usually lost too. One exception was a freeze-sensitive *Coelocnemis magna* LeC.[6], which was collected in the mountains in the summer, and which had nucleating agents in its haemolymph. No other beetles had haemolymph which altered the supercooling points of NaCl solutions significantly, indicating that the haemolymph of these species lacked nucleating agents. The coastal species were not examined with respect to freeze tolerance, but they were presumably freeze sensitive. These results suggest that only freeze-tolerant species have nucleating agents in their haemolymph, and that these agents are usually present in winter only.

Table 1 shows that summer beetles of the freeze-tolerant species, which lacked nucleating agents in their haemolymph, had supercooling points 1–3 °C lower than beetles collected in winter. This indicates the presence of other, possibly intracellular, nucleating agents, the effect of which would be masked by the nucleating agents in the haemolymph during winter.

When freeze-tolerant *E. blanchardi* were kept at +20 °C for 2 weeks (not shown in Table 1), they became sensitive to freezing. The nucleating effect of their haemolymph, however, was still present, and the supercooling points of the intact beetles did not change, indicating that freezing at high subzero temperatures in itself does not make the beetles freeze tolerant. Furthermore, it reveals that in these

Fig. 1 Supercooling points of solutions of NaCl (○) and glycerol (△), solutions of NaCl (●) and glycerol (▲) containing 5% of haemolymph from freeze-tolerant *Eleodes blanchardi*, and solutions of NaCl (⊗) containing 5% of the same haemolymph previously heated to +100 °C for 5 min, all plotted as a function of the osmolality of the solutions. Each point is the mean of 4–12 parallel 5-μl samples, and the bars represent the standard deviation. The regression line of points representing solutions containing native haemolymph is indicated by the solid line, and the theoretical melting points are indicated by the dashed line. The osmolality is calculated from the concentration of solute according to data from the *Handbook of Chemistry and Physics*[8]. The change in osmolality caused by the addition of haemolymph to the solutions is small and has not been adjusted for in the calculations.



circumstances there is a time lag between the inactivation of the nucleating agents and that of other factors which cause freeze tolerance in the beetles. A similar time lag might explain the presence of nucleating agents in the haemolymph of the freeze-sensitive *C. magna* (Table 1).

To learn more about the properties of the ice nucleators in the haemolymph, we examined the effect of haemolymph from *E. blanchardi* on the supercooling points of solutions of NaCl and glycerol. Several concentrations of solutes were used, so that the osmolality varied from near 0 to about 2 osmol. Corresponding values of osmolality and supercooling points of both pure solutions and solutions containing haemolymph are shown in Fig. 1, which shows that haemolymph from *E. blanchardi* caused a considerable increase in the supercooling points of the solutions. The supercooling points of solutions containing haemolymph are linearly related to the osmolality, and the points representing NaCl and glycerol solutions lie on the same line, indicating that the effect of glycerol is due only to its osmotic activity. The calculated regression line for all points representing solutions containing haemolymph has the formula

$$y = -5.3 - 1.95x$$

The slope of this line (-1.95 °C per osmol) is approximately the same as the osmolal freezing point depression (-1.86 °C per osmol), which is indicated by the dashed line on Fig. 1. Thus the supercooling capacity of solutions containing haemolymph does not change significantly as the osmolality of the solution changes, indicating that the nucleating agents induce freezing at a certain degree of supercooling, regardless of the osmolality of the solutions. This degree of supercooling corresponds to the difference in ordinate values of the two lines, that is 5.3 °C. The dispersion of the points around the regression line is remarkably low, suggesting that when the solutions are supercooled by 5.3 °C, there is a large increase in the statistical probability that an ice nucleus will form.

By heating the haemolymph to +100 °C for 5 min before it was added to the solutions, the supercooling points were lowered markedly, indicating that the nucleating agents are temperature sensitive. Some nucleating effect was still present, however, since the new supercooling points were still above those of solutions without haemolymph.

Freeze tolerance in adult insects has been known only during the past few years, and little is known about the mechanisms involved. Data from different kinds of freeze-tolerant organisms, including beetles[2], indicate that ice formation is limited to the extracellular compartments, and that extracellular ice protects the organisms against intracellular freezing, which is believed to be injurious. According to this model, extracellular ice, which is considered to be unable to penetrate cell membranes, concentrates the extracellular solutes and causes an osmotic flux of water out of the cells. Thus, at sufficiently low freezing rates, allowing water to leave the cells as the freezing proceeds, the intracellular as well as the extracellular fluid would be kept at or near its melting point[7]. Consequently, the probability of an injurious intracellular freezing would become very small. The presence of nucleating agents in the haemolymph of freeze-tolerant beetles, ensuring extracellular freezing at high subzero temperatures, gives further support to this model.

Induction of male recombination in *Drosophila melanogaster* by injection of extracts of flies showing male recombination

MORGAN[1,2] was the first to report that no spontaneous recombination occurs in males of *Drosophila melanogaster*. Since then recombination has been induced in *D.melanogaster* males by various treatments[3], for example, X rays. In an attempt to study the control of recombination in *D. melanogaster*, Reddi *et al.*[4] injected males with ovarian extracts and, surprisingly, induced recombination. Subsequent attempts to repeat this experiment failed[5,6]. It is known that some natural populations of *D. melanogaster* show spontaneous male recombination[7-10], and it has been suggested that this may be caused by episomes or viruses[8,9,11]. It is therefore possible that these male recombination-inducing factors could be transferred by injection, and that the failure to reproduce these results[4] might have been due to the use of strains lacking such factors. We have therefore tested whether or not male recombination could be induced by injecting extracts of flies from strains showing male recombination into flies lacking male recombination.

An extract of *OKI* flies, a strain from Oklahoma that shows male recombination[12], was prepared by homogenising together 10 each of newly emerged males and females in 4 ml of *Drosophila* Ringer solution, and centrifuging at 2,000 r.p.m. for 2 min. The supernatant was injected into virgin females which were homozygous for the recessive chromosome markers, *dp b cn bw; ve* (dumpy wings, 2–13.0, black body colour, 2–48.0, cinnabar eye colour, 2–57.5; brown eye colour, 2–104.5; veinlet wings, 3–0.2) until their abdomens were visibly distended. These females were mated individually to *Canton-S* (*CS*) males, a wild-type strain which when crossed to the marker strain gives F_1 males that produce no recombinants. The heterozygous male progeny were mated individually to *dp b cn bw; ve* females every 3–5 d for a total of four transfers. Their progeny were then scored for second chromosome male recombination. All presumptive recombinants were tested by backcrosses to *dp b cn bw; ve* flies. Control flies were injected with *CS* fly extract or *Drosophila* Ringer solution.

The results are summarised in Table 1. Male recombination occurred only in sons of females injected with *OKI* extract. The pattern of recombination along the second chromosome (Table 1) was similar to that found in *OKI/dp b cn bw* males[12], in that the events occurred mainly in the centromeric region (*b–cn*) and in the right arm (*cn–bw*). In addition, the distribution of recombination events does not fit a Poisson distribution (index of dispersion $x_{51}{}^2 = 163.5$, $P < 0.001$). Some of these induced recombination events therefore occurred as clusters, suggesting a premeiotic origin. A similar observation has been made with *OKI/dp b cn bw* flies (unpublished results of R. C. W. and J. N. Thompson). It should also be noted that the factor(s) causing male recombination could be transmitted over at least one generation.

In a second experiment 1–2-d-old *CS/dp b cn bw; CS/ve* males were injected with an *OKI* ovarian extract prepared by dissecting 100 fertilised *OKI* ovaries into 0.1 ml of a 0.4% saline solution, homogenising and centrifuging at 14,500 r.p.m. for 12 min. Control males were injected with a similarly prepared *CS* ovarian extract, or were left uninjected. After 1 or 2 d, injected

*The frequencies of male recombination among males that showed recombination in experiment 1 was 17/1845 = 0.92%, and in experiment 2, 8/1135 = 0.71%.
†These results are significantly different from the controls at the 0.1% level by Fisher's exact test.

males were mated individually to *dp b cn bw; ve* virgin females for 4 d and then were remated every 3 d to fresh *dp b cn bw*; *ve* virgin females for five broods. The progeny were scored for second chromosome male recombination.

The results (summarised in Table 1), support those of the first experiment, and suggest that the factor(s) can be transferred by ovarian extracts.

As a further statistical test on the combined data from this study, a Fisher's exact test was performed on the number of *OK1* extract-treated males that produced any recombinant progeny (10/102) compared with the corresponding number of control males (*CS* and Ringer-injected) (0/202). These results show that significantly more treated males showed recombination than did control males ($P = 0.000025$).

The results of the previous attempts[4-6] to induce male recombination by ovarian extract injections can be explained if Reddi *et al.*[4] injected an ovarian extract from flies showing male recombination, and the others[5,6] did not. Further experiments are planned to investigate the nature of the male recombination-inducing factor in the extracts of *OK1* flies.

We thank Professor J. M. Thoday and Drs M. Ashburner, J. Holden and G. P. Richards for discussions and suggestions, and Miss A. Forster for technical assistance.

Note added in proof: Slatko and Hiraizumi (personal communication), using a *D. melanogaster* line that contains the *Male recombination* element, have observed results similar to those in this article.

Initiation of meiotic maturation in *Xenopus laevis* oocytes by lanthanum

PROGESTERONE can induce true maturation of isolated amphibian oocytes *in vitro*[1]. It has been found recently that the ionophore A23187, in the presence of high magnesium or calcium concentrations, can also promote meiosis *in vitro*[2], and it has been observed that 0.5–1 mM propranolol and some related compounds, are potent inducers of maturational events in *Xenopus laevis* oocytes[3]. This last result suggests that displacement of membrane calcium might be involved in maturation, because this is known to occur in other systems treated with high concentrations of propranolol[4]. We have therefore studied the action of La^{3+}, since this ion is expected to act specifically at the superficial plasma membrane calcium sites[5]. We report here that maturation is induced by La^{3+}, indicating strongly that calcium ion movements have a role in the initiation of oocyte maturation.

Ovarian tissues were removed from *Xenopus laevis* females through a small incision made on the lateral abdominal wall. To obtain fully grown oocytes free of follicle cells, the ovaries were treated with collagenase[6]. In each experiment, all oocytes were obtained from the same animal. The experiments were conducted at room temperature, in a modified Ringer solution to which La^{3+} was added as the chloride salt. La^{3+} at 5 or 10 mM promotes maturational events in *Xenopus laevis* oocytes (Table 1). The maturation is not abortive, since microscopic examination reveals the existence of the spindle moving to the cortex (Fig. 1). La^{3+}-induced maturation presents several other characteristics common to progesterone-induced maturation. The breakdown of the germinal vesicle takes place after about the same length of incubation, and maturational responses to both agents are inhibited by cycloheximide (Table 1; ref. 7); La^{3+}, like progesterone, is not able to induce maturation when injected into the oocytes (data not shown).

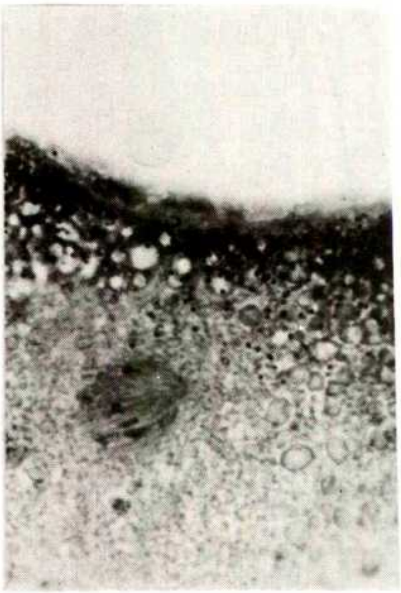
Table 1 Maturation of *Xenopus laevis* oocytes, as indicated by germinal vesicle breakdown, after continuous exposure to lanthanum or progesterone

Treatment		Female *A*	*B*	*C*
Modified Ringer		0	0	0
La^{3+}(mM)	0.01	—	—	0
	0.1	—	—	2
	0.5	—	—	3
	1	0	—	5
	2.5	50	—	
	5	60	55	72
	10	75	62	92
La^{3+} (mM) + cycloheximide (100 μg ml^{-1})	10	0	0	0
Progesterone (1 μg ml^{-1})		97	100	91

One hundred isolated oocytes were used for each set of conditions. The table shows the number of matured oocytes after 15 h incubation. La^{3+} was administered in solution as the chloride salt in Ringer solution containing no bicarbonate buffer.
—, Not tested.

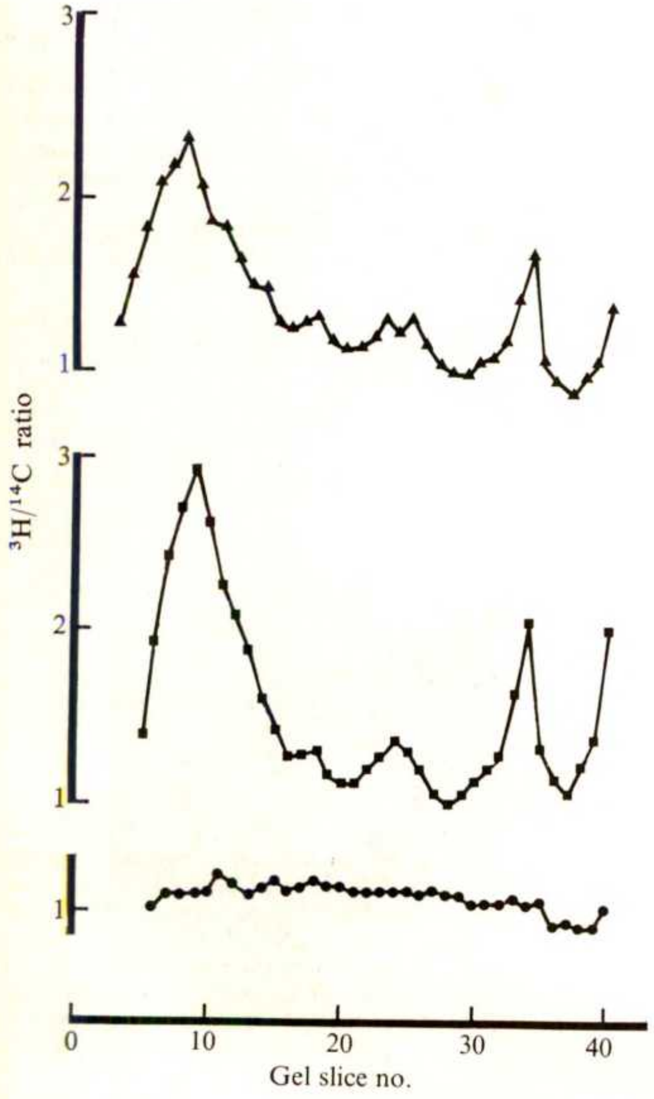
Furthermore, a similar preferential protein synthesis is activated by progesterone and La^{3+}. It has been shown previously that during progesterone-induced maturation *in vitro*, several electrophoretically defined soluble proteins are increased selectively[8]. We studied this effect by double labelling of proteins, injecting ^{3}H-leucine into treated oocytes (maturing) and ^{14}C-leucine into control oocytes (resting)

Fig. 1 Meiotic metaphase of oocyte in which maturation was induced *in vitro* by La^{3+}, at 5 mM (chloride salt). Magnification × 800. The oocyte was fixed in Smith's solution. Sections (7 μm) were stained with Feulgen's reagent and counterstained with light-green.



(Fig. 2). Control/control experiments with injection of ^{3}H- and ^{14}C-leucine into non-treated oocytes did not show any peaks, and the ^{3}H/^{14}C ratio of electrophoresed proteins was normalised to 1. The same pattern of induced proteins was observed when La^{3+} was substituted for progesterone (Fig. 2). In each case, two distinct peaks were found, with several smaller peaks in between. For both these agents, the increase above the control ^{3}H/^{14}C ratio was 150–200% for the small molecular weight peak and 130–150% for the large molecular weight peak.

Fig. 2 Normalised gel electrophoresis patterns of proteins during maturation induced by progesterone (▲) and La^{3+} (■). The curves show ^{3}H/^{14}C ratios, expressed as the percentage increase above the controls (●). Labelling was for 2 h beginning approximately 15 h after continuous exposure to progesterone or La^{3+}. Twenty-five matured oocytes were injected with 70 nl of ^{3}H-Leu and 25 non-treated oocytes were injected with 70 nl of ^{14}C-Leu. Control/control (●) was performed by injecting 25 non-treated oocytes with ^{3}H-Leu and 25 other non-treated oocytes with ^{14}C-Leu (^{3}H-Leu, 55 Ci mmol^{-1}; ^{14}C-Leu, 324 mCi mmol^{-1}, Amersham). Appropriate amounts of non-radioactive amino acids were added to obtain identical concentrations of ^{3}H- and ^{14}C-amino acids and a ^{3}H/^{14}C d.p.m. ratio of about 10. Treated and control oocytes were pooled and homogenised in 2 ml of saline solution. The 105,000*g* supernatant was obtained and dialysed as reported previously[8]. Sodium dodecyl sulphate (0.1%)–polyacrylamide gel (6%) electrophoresis was performed under 2 mA per tube for 20 min and then 5 mA per tube (migration towards anode on the left). Gels were re-electrophoresed in 7% acetic during 2 h and sliced immediately. Soluene (0.5 ml) was added and the supernatant left for 3 h at 50 °C. Radioactivity was then counted in an appropriate scintillation mixture. Left peak, histones migrate at this level; right peak (higher molecular weight), molecular weight greater than 100,000. Other details are in ref. 12.



Incubation in Ca^{2+} alone in high concentration does not lead to maturation[2]. Although ionophore A23187 induces maturation in amphibian oocytes given certain conditions of divalent ionic concentration[2], La^{3+} seems to be a more appropriate agent to investigate the possible involvement of Ca^{2+} in this, and other systems[5,9]. High concentrations of extracellular La^{3+} displace external membrane calcium, and block both Ca^{2+} uptake and efflux, resulting in a release of internal sequestered Ca^{2+} (ref. 5). Our finding that La^{3+} induces maturation makes it likely that Ca^{2+} is involved in the initiation of maturation. Since injected Ca^{2+} is without effect[10], however, it must be that the Ca^{2+} movements involved are highly regulated, or need to be sustained during the period of maturation. Injected La^{3+} is without effect, probably because it is unable to react with the appropriate membrane sites.

The present results imply that progesterone, the likely physiological inducing agent[11], acts at specific membrane sites, leading to well defined movements of Ca^{2+} inside the cell. The altered Ca^{2+} distribution would in turn be the intermediary step for the series of further events promoting maturation.

This work was supported by grants from the SNSF and WHO. We thank Dr G. Jones for help with the preparation of the manuscript, Dr Y. Timowska for scientific assistance and Mrs M. Romios for technical help.

Benzpyrene induces sister chromatid exchanges in cultured human lymphocytes

A WIDE variety of chemical mutagen/carcinogens induce sister chromatid exchanges (SCE) in cultured Chinese hamster cells and can thus be studied at the chromosomal level[1,2]. Certain polycyclic hydrocarbons, such as benzo(*a*)-pyrene, 3-methylcholanthrene, dimethylbenzanthracene and others are important in the aetiology of human bronchial carcinoma[3]. The substances are not themselves carcinogenic, but are converted to carcinogenic epoxides by the enzyme arylhydrocarbonhydroxylase.[4] Epoxides bind non-enzymatically to DNA, unless they are converted enzymatically to inert water-soluble metabolites by epoxide hydratase[5] and glutathione-*S*-transferase[6]. The carcinogenic effect of polycyclic hydrocarbons is closely connected with the regulation of the enzyme activities and genetic variability can thus be expected. It has been observed at the population level by family studies[7] and at the cellular level by biochemical differences in the hydrocarbon-degrading enzyme system[8]. We have investigated the possible induction of sister chromatid exchanges by benzo(*a*)pyrene and show that the rate of SCE does not correlate with different rates of benzpyrene metabolism. We therefore suggest that genetic differences in benzpyrene metabolism are unrelated to genetic variation in the predisposition to bronchial carcinomas.

We tested the intracellular benzo(*a*)pyrene (BP) metabolism by measuring the formation of tritiated H_2O-soluble products from ^{3}H-BP in cultured lymphocytes isolated by a Ficoll–Hypaque gradient as described in Fig. 1. An inhibitor of the monooxygenase system[9], alpha-naphthylflavone (ANF, 5 μg ml^{-1}) was used as a control. We found wide individual differences in BP metabolism among 22 individuals. The one with the highest metabolic activity (WW) showed 3.8 ± 0.5 times the activity of the lowest (HR) in each of six independent determinations. ANF reduced the amount of water-soluble products to background levels in both.

To determine sister chromatid exchange rate (SCE), 10^8 isolated lymphocytes were incubated in 5 ml of chromosome medium Ia (Gibco) together with 5-bromodeoxyuridine (BUdR) (30 μg ml^{-1}) for 70 h at 37 °C in the dark. Parallel assays were made in duplicate with 10^{-6} M BP and 55 μg ml^{-1} ANF. Chromosomes were prepared by standard techniques and the slides were stained with acridine orange (125 μg ml^{-1}) in phosphate buffer at *p*H 6.0 and analysed by fluorescence microscopy.

The results are summarised in Fig. 1. The SCE rate nearly doubled after incubation with BP, but not in the presence of ANF (55 μg ml^{-1}). This concentration inhibits the formation of water-soluble products by more than 95%. Benzpyrene failed to induce SCEs when it was present for only 30 h of culture, instead of the usual 70 h, and it did not influence the total number of second generation metaphases found at 70 h. The fast (WW) and the slow (HR) BP-metabolising individuals did not differ in the rate of SCE induction.

This result, at first surprising, corresponds to differences in BP metabolism between different strains of mice which, nevertheless, do not differ in the rate of benzpyrene-induced tumours[10,11]. The inhibition of the first BP-oxidising step (AHH) by ANF prevents the carcinogenic effect of BP as indicated by the normal SCE induction. The similar SCE induction between the high (WW) and the low (HR) BP-metabolising individuals (Fig. 2) indicates, however, that BP metabolism and carcinogenesis are not related in a simple, proportional way[12]. A high rate of benzpyrene conversion cannot serve as an indication of the effective concentration of carcinogenic epoxides and their effects on DNA. The formation of water-soluble products from BP only indicates that BP is being degraded, but does not give any information about the current levels of ultimate carcinogens formed during this steady-state process. How much epoxide binds to DNA is also unknown. Finally, we do not know how much epoxide is removed by DNA repair and how much remains fixed in the DNA following the next replication.

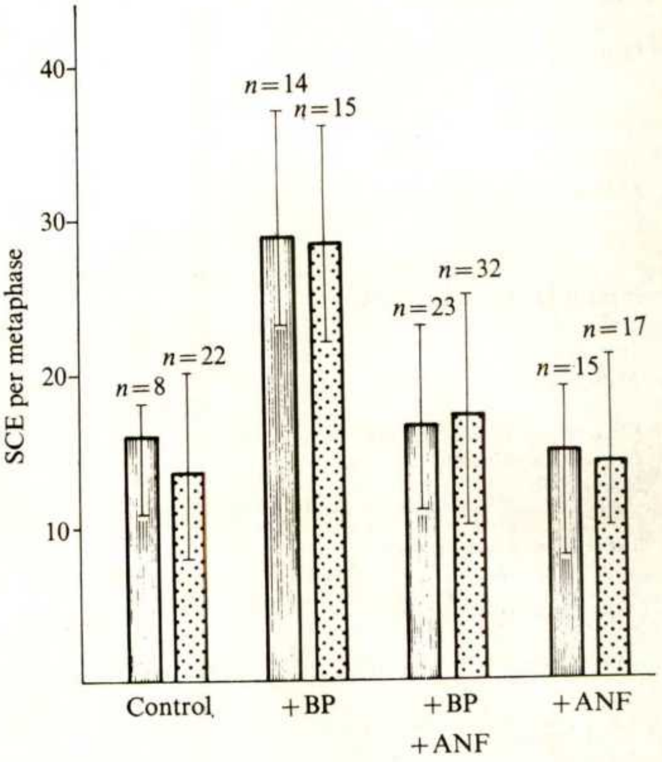

Fig. 1 Induction of sister chromatid exchanges (SCE) by benzypyrene (BP) and its inhibition by alpha-naphthylflavone in lymphocyte cultures with different rates of intracellular BP metabolism. Lymphocytes were isolated from 20 ml of heparinised blood by a Ficoll–Hypaque gradient[13] which yielded a 70–85% pure preparation of about 2×70^7 lymphocytes. The BP metabolism was determined by seeding 5×10^5 cells into each of 96 wells of a Cook's microtitre plate (Falcon, Oxnard, California) together with 200 µl of Ham's F-12 culture medium containing 16% foetal calf serum and 150 nM of ^{3}H-BP (specific activity 25 Ci mmol^{-1}, (Amersham-Buchler, Braunschweig, Germany). Water-soluble products were determined after 8 h of incubation by the method of Huberman and Sachs[14]. SCEs were scored in phytohaemagglutinin-stimulated lymphocytes after 70 h of incubation at 37 °C. The height of the columns (shaded, fast; dotted, slow, BP-metabolising individual) indicate the mean and the bars the range of SCE per metaphase. Benzo(*a*)pyrene (Sigma) was dissolved in chloroform : methanol (2:1), extracted twice by equal amounts of 1 N NaOH and recrystallised from the organic phase in the cold. A stock solution (10 mM) of BP in acetone was mixed with a 40-fold amount of foetal bovine serum and added to the series indicated to give a final BP concentration of 1 µM. The monooxygenase inhibitor ANF (Fluka) was also first dissolved in acetone mixed with foetal bovine serum and added where indicated at a final concentration of 55 µg ml^{-1}. The rate of SCE induction in the presence of the inhibitor does not differ from cultures without BP or controls. There is only a minimal SCE induction by BP, in the presence of ANF, probably as a result of incomplete inhibition of the monooxygenase system. At the concentration used, formation of water-soluble products was less than 5% of controls without ANF.

The induction of SCEs by benzpyrene reported here probably reflects the intracellular carcinogenic effect of benzpyrene, although it is not understood in molecular terms. The lack of correlation between the activity of intracellular benzpyrene metabolism and SCE rate suggests that genetic differences in BP metabolism are not related to genetic differences in the predisposition towards development of bronchial carcinoma as revealed by family studies[7]. How the rate of benzpyrene-induced sister chromatid exchanges differs between patients with bronchial carcinoma and control patients is being investigated.

Expression of maternal and paternal antigens on trophoblast

GENETICALLY different individuals will not usually accept tissue grafts from one another. The best known exception to this is the ability of the foetus to act as a homograft. Fertilised mouse eggs contain both paternally and maternally derived antigens[1,2], but it has not so far been demonstrated whether paternal antigens are expressed on mouse trophoblast, the embryo tissue which forms initial contact with the maternal circulation. If present, such antigens may be masked by a mucopolysaccharide[3]; this has been disputed by Simmons *et al.*[4]. Alternatively, it has been proposed that trophoblast lacks transplantation antigens[5] and Searle *et al.*[6] failed to immunise a recipient with mouse trophoblast when tested either by skin grafting or cell-mediated cytotoxicity. It has been suggested, however, that histocompatibility antigens on human trophoblast were responsible for cytotoxic antibody found in the sera of 12-week human pregnancies[7], and Nakakita showed antibody production in mice to human trophoblast, using immune adherence[8]. I now report the presence of both paternal and maternal antigens on trophoblast outgrowths of mouse blastocysts *in vitro*.

Blastocysts flushed from the uteri of either CBA/Fa or C57 BL/Mcl females 3.5 d after coitus were cultured on glass coverslips. On day 4 of culture, the mixed immune haemadsorption technique[10] (MHA) modified by Tachibana *et al.*[11] was used to detect antigens on the outgrowths. Trophoblast and indicator cells (sheep red blood cells) were coated with specific antisera raised in mice, and linked together by a rabbit anti-mouse IgG serum (Capell Laboratories). Photographs were taken as a cross check. Figure 1 shows a 3.0 reaction. The attachment of sensitised red cells to trophoblast outgrowths from crosses of (CBA × CBA), (C57BL × CBA) and (CBA × C57BL) incubated with anti-CBA serum (Fig. 2) shows that both maternal and paternal antigens are expressed on the trophoblast. For each pair of crosses the difference between the mean degree of red-cell attachment was significant ($P < 0.01$). This suggests that the amount of CBA antigen present is greater with a CBA mother than with a CBA father, and greater still when both parents are CBA. Control data for (CBA × CBA) trophoblast outgrowths are shown in Table 1. Normal CBA or C57BL sera and anti-C57BL serum gave scores of 0. After absorption

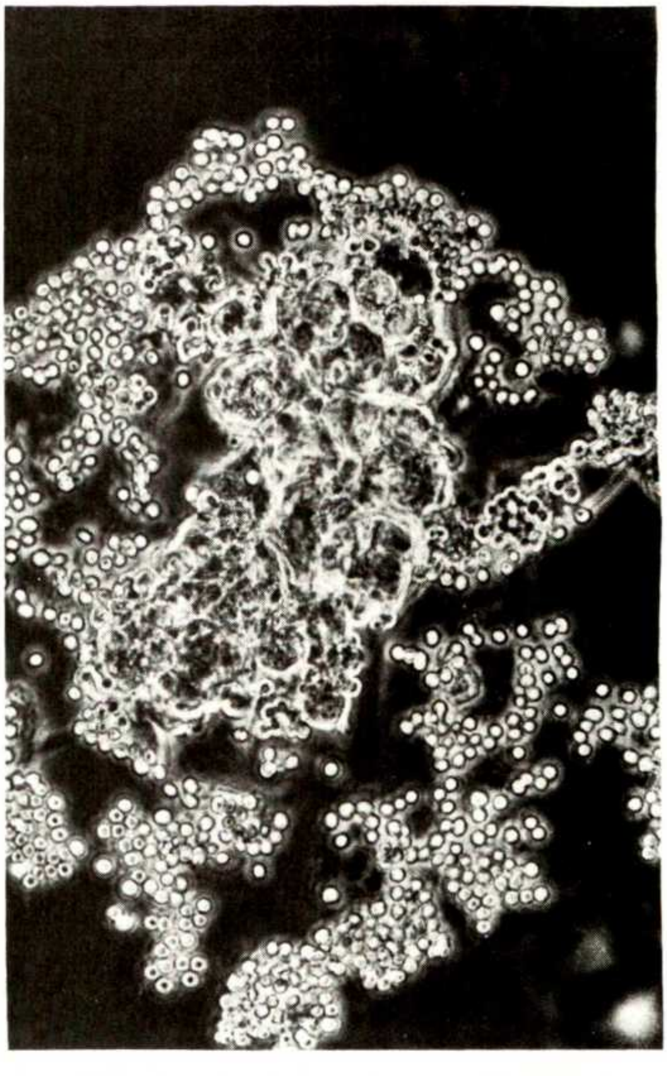

Fig. 1 A (C57BL × CBA) blastocyst cultured in Snow's medium[9] and 10% foetal calf serum under oil and incubated at 37 °C in an atmosphere of 10% CO_2 in air. Attachment of sensitised red cells to the resulting outgrowth after MHA is shown. Antiserum to a mixture of male and female CBA/Fa spleen cells was raised in C57BL/Mcl mice. Approximately half a donor spleen was given to each recipient weekly for between 7 and 10 weeks. Antiserum to the sheep erythrocytes was raised in A-strain mice. Recipients were given 0.2 ml of a 1% suspension of sheep red blood cells (SRBC) each week for between 7 and 10 weeks. Optimal conditions for the sensitisation of SRBCs were established. After washing three times in phosphate-buffered saline (PBS) they were incubated in a 1:1,000 dilution of anti-SRBC serum followed by a 1:100 dilution of anti-mouse IgG serum and finally diluted to 4% (v/v) and stored at 4 °C. There were three washes with PBS between each step in the procedure. On day 4, outgrowths on coverslips were rinsed in PBS and incubated for 1 h with selected antisera, rinsed and layered with sensitised SRBCs (1.0% v/v). After 1 h at room temperature, unattached erythrocytes were washed off and the strength of the reaction was estimated microscopically according to the percentage of target cells (that is, trophoblast of the outgrowth) to which sensitised SRBCs were attached, expressed on the following scale: 4.0 (100% attachment); 3.5 (90%); 3.0 (50–80%); 2.0 (<50%); 1.0 (<25%); 0.5 (<10%); 0 (0%). The above outgrowth was given a score of 3.0.

Table 1 Expression of CBA cell-surface antigens on trophoblast outgrowths of blastocysts from a CBA×CBA mating after incubation with control sera

Serum	Cell type used for absorption	Serum dilution	Mean score±s.e.m.	
Anti-CBA	—	1:160	3.80±0.06	(34)
Anti-CBA	CBA liver and spleen	1:160	2.00*	(3)
Anti-CBA	C57BL liver and spleen	1:160	3.75±0.25	(4)
Anti-CBA	CBA lymph node and spleen	1:160	0.52±0.07*	(24)
Anti-CBA	C57BL lymph node and spleen	1:160	3.84±0.05	(29)
Normal CBA	—	1:40	0	(13)
Normal C57BL	—	1:40	0	(10)
Anti-C57BL	—	1:40	0	(20)

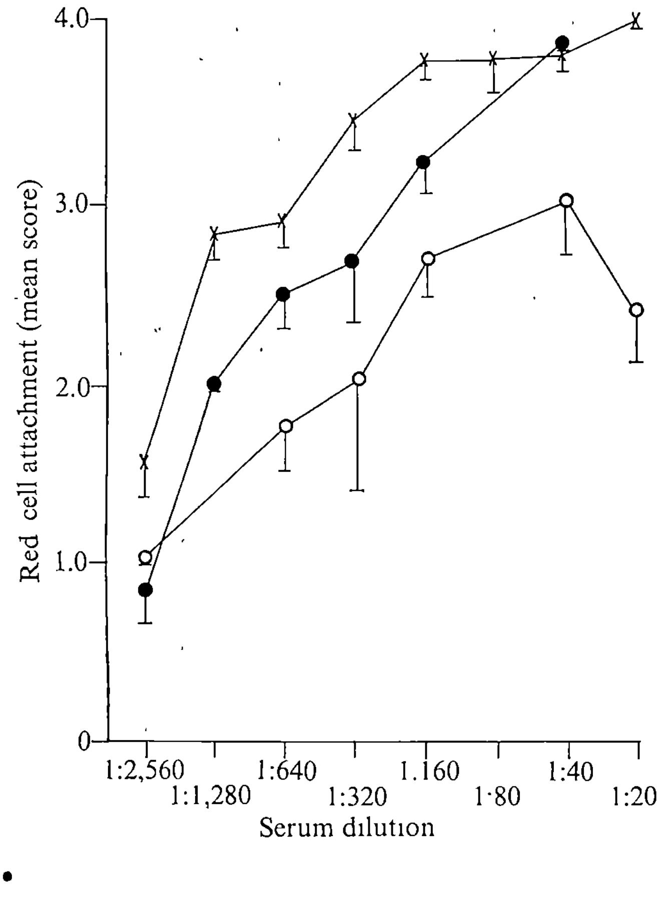
Absorptions were carried out with a 50:50 mixture of washed liver and spleen cells or lymph node and spleen cells for 2×1 h at 37 °C. Results are expressed as mean score ± s.e.m. The number of outgrowths per group is in parentheses.
$^*P < 0.001$ for corresponding controls.

Table 2 Expression of C57BL cell-surface antigens on trophoblast outgrowths after incubation with normal sera, anti-C57BL serum, or absorbed anti-C57BL serum, diluted 1:40

Origin of blastocysts Mother Father	Anti-C57BL serum	Anti-C57BL serum absorbed with C57BL cells	Anti-C57BL serum absorbed with CBA cells	Normal C57BL serum	Normal CBA serum	Anti-CBA serum 1:160
C57BL×C57BL	3.86±0.14 (4)	1.00±0.14* (10)	3.38±0.34 (8)	0 (4)	0 (4)	0 (10)
CBA×C57BL	3.31±0.23 (13)	1.00 (2)	3.00 (2)	—	—	—
C57BL×CBA	3.00 (2)	0.89±0.07* (9)	3.00±0.37 (6)	—	—	—

Absorptions were carried out with a 50.50 mixture of washed spleen cells and lymph node cells for 2×1 h at 37 °C. Results are expressed as mean score ± s.e.m. The number of outgrowths per group is in parentheses.
$^*P < 0.001$ for corresponding controls

Fig. 2 The expression of CBA cell surface antigens on trophoblast outgrowths after incubation with serial dilutions of anti-CBA serum. Blastocysts were recovered from CBA females mated to CBA (×) or C57BL (●) males, and from C57BL females mated to CBA males (○) Data were accumulated from 14 experiments A least squares analysis of variance according to the method of fitting constants[12] gave a mean square value of 0.2623 with 152 residual degrees of freedom. Duncan's new multiple range test[13] was used to analyse the difference between the means of the three crosses ($P < 0.01$)



of the anti-CBA serum with a mixture of spleen and lymph node cells from CBA mice, red-cell attachment was reduced by 86%. Total absorption of the activity was not expected because the antiserum was made to both intracellular and cell membrane-bound antigens of spleen cells, whereas the absorption would only remove antibodies raised against the latter. A mixture of CBA liver and spleen cells only reduced the reaction by 50%. Absorption with C57BL cells had no effect.

Table 2 shows results obtained with blastocysts from (C57BL×C57BL), (CBA×C57BL) and (C57BL×CBA) matings incubated with anti-C57BL serum and control sera. Both maternal and paternal antigens are present but a comparison of their relative expression cannot be made because of the small number of outgrowths studied when the C57BL is the mother.

These experiments show that trophoblast *in vitro* exhibits antigenicity derived from both the maternal and paternal genome. The antigens expressed could be either major histocompatibility antigens of the H-2 type or minor antigens (for example, H-3, H-6), since both are present on spleen cells.

I thank Dr A. McLaren, Dr J. Ansell, Dr R. Hancock and G. Mahon for criticism and advice. This work was supported by the Ford Foundation.

Successful induction of specific tolerance to transplantation antigens using autoimmunisation against the recipient's own natural antibodies

ORGAN transplantation, especially of kidneys, is now an accepted method in medical care. In spite of careful matching to obtain the most suitable combination between donor and recipients as to blood group and HLA antigens, varying degrees of incompatibility have to be accepted. This makes prolonged use of immunosuppressive drugs necessary. Such therapy, however, may in itself cause serious and even lethal complications. Specific tolerance to the donor antigens with full reactivity against other antigens is the ideal. Classical induction of transplantation tolerance requires massive inoculation of foreign cells, may result in serious graft-*versus*-host reactions and is not considered feasible in human kidney grafts. We describe here a new method of inducing specific immune tolerance to a given set of alloantigens, which can be carried out in adults and which will leave reactivity against other antigens intact.

Every individual seems to have lymphocytes with predetermined receptors for various parts of the major histocompatibility complex antigens of the species. When tested against a given set of such MRC antigens, 3–10% of a normal mouse or rat T-lymphocyte population will express immune competence[1,2] or specific receptors for antigens of that particular MHC locus[3,4]. These receptors can be characterised according to two characteristics, their specific antigen-binding capacity and their unique antigenic or idiotypic markers[5,6]. Two other facts make these receptors useful for the induction of specific immune tolerance. They are found in detectable amounts in normal serum or urine of the individual[7]. It can be shown that the individual is able to produce specific anti-receptor antibodies against its own naturally occurring receptors, if the latter are presented to the individual in a concentrated, modified form. We describe results showing the validity of the latter statement.

Normal Lewis rats (MHC type Ag-B^1) have in their sera or urine idiotypic receptor molecules with specificity for other Ag-B alloantigens, e.g. against DA (Ag-B^4) and BN (Ag-B^3). Using anti-(Lewis-anti-DA) idiotypic antibodies linked to Sepharose it is possible to isolate the anti-DA receptors from normal Lewis serum[7]. Normal Lewis serum (300 ml) was thus passed over such an anti-idiotypic column and the bound material was acid eluted and cross linked with glutaraldehyde[8]. Cross-linked material (20 μg) in Freund's complete adjuvant was injected subcutaneously into each of four normal adult Lewis rats. The animals received a boost on day 21. On day 40 the animals were bled and their blood lymphocytes used as responder cells in MLC tests against DA or BN. Four days later the animals received DA skin grafts on the left back side and BN grafts on the right side.

Table 2 Delayed rejection of DA skin on immunised Lewis rats

Immunised Lewis rats No	Rejection of DA skin on day	Mean	Rejection of BN skin on day	Mean
1	21	30.3	12	11.8
2	35		11	
3	27		11	
4	38		13	

Three control normal Lewis rats rejected DA skin between day 9 and 10 and BN skin between day 10 and 12. Full thickness skin grafts were carried out as described elsewhere[10].

As shown in Table 1, these Lewis rats showed a specific lack of reactivity against DA alloantigens in the MLC and they accepted DA skin grafts for some 30 d (See Table 2). Reactivity against BN alloantigens was in both tests completely normal. In three similar experiments with skin grafts essentially the same results were obtained. The mean survival of DA or (Lewis ×DA)F$_1$ skin grafts on 20 adult Lewis rats treated in the above way was 24±1.7 (s.e.) days. BN or (Lewis×BN)F$_1$ grafts were all rejected within 11 d.

On day 91 the animals were bled again and their sera tested, after extensive absorption with (L×DA)F$_1$ lymphocytes in order to remove possible anti-DA alloantibodies produced after skin rejection, for the ability to bind to normal Lewis or DA T lymphocytes using as second layer ^{125}I-protein A as an indicator for surface-bound IgG antibodies[5]. All sera contained antibodies capable of reacting with normal Lewis lymphocytes but not with DA lymphocytes. To prove the auto-anti-idiotypic nature of these autoantibodies the sera were now tested for their ability to cause specific inhibition of MLC as had previously been done using "conventional" anti-idiotypic antibodies[5].

As shown in Table 3, treatment of normal Lewis T lymphocytes with the antisera in the presence of complement did result in a highly reduced activity against DA but not against BN alloantigens in the MLC test. Thus, the autoantisera did indeed contain the expected anti-idiotypic antibodies.

Finally, on day 91 after the bleeding, each of the animals was inoculated with 2.5×10^7 (Lewis ×DA)F$_1$ and (Lewis×BN)F$_1$ lymphocytes. Animals were killed 10 d later and their antisera were tested for alloantibodies using the protein A test. Then weak alloantibody titres against DA alloantigens could be detected in the autoimmunised animals, ranging from 1:32 to 1:256. Whether these alloantibodies contained the "normal" Lewis-anti-DA idiotypes was not tested. The control animals treated in exactly the same way as the experimental animals except for the immunisation with idiotypic receptors had anti-DA titres ranging from 1:4,096 to 1:16,384. Both groups of animals had similar titres against BN alloantigens (range 1:2,048 to 1:4,096). Thus, not only did the auto-anti-idiotypic

The MLC was performed in flat-bottom microtitre plates in EHAA medium[9] complemented with the double amount of glutamine and 0 5% fresh normal BN rat serum using 0.25×10^6 responder cells and 0.5×10^6 spleen cells irradiated with 2,000 R as stimulator cells. Cultures were collected after 120 h after a 6-h pulse with 1 μCi of ^{3}H-TdR (ref. 5) Stimulator cells alone gave between 200 and 400 c.p.m.

Conditions for the MLC essentially the same as in Table 1. For further details for the treatment of the responder cells with antiserum and complement see ref. 5. Sera from another group of immunised Lewis animals inhibited MLC completely in a specific way.
*Values significantly different from values of normal Lewis serum and complement-treated groups are underlined

reaction significantly and specifically wipe out the T-cell mediated reactivity against the relevant alloantigens but there was also a drastic reduction in the alloantibody producing ability of these individuals. Using lymphocytes from auto-idiotype-immunised rats we have also been able to demonstrate that they largely lack the corresponding idiotypes, for example Lewis rats immunised with Lewis-anti-DA receptors lack lymphocytes with idiotypes signifying anti-DA reactivity but show normal distribution of anti-BN idiotype positive lymphocytes. Whether this reduction is particularly pronounced in the B-or the T-lymphocyte population is unknown.

We have thus presented data demonstrating that selective autoimmunity against a given group of antigen-binding receptors can lead to specific immune tolerance, probably due to the physical elimination of this group of immunocompetent cells. No side effects of this autoimmune procedure have so far been noted and the individuals express completely normal reactivity against other antigens. The skin-graft tolerance is highly significant; as in the rat many minor as well as the major Ag-B locus antigens do contribute to skin-graft rejection. In spite of this, grafts often survived for up to a month in the absence of any nonspecific immunosuppressive therapy. It thus seems clear that our techniques may allow the induction of long lasting immune tolerance through autoimmune reactions against the relevant idiotypic receptors. The specificity of this procedure would be as high as that of 'classical' immune tolerance and could in particular be carried out in adult, immunocompetent individuals. Improvements to make the approach more general by testing other species of animals and using alloantigenic immunosorbants instead of anti-idiotypic immunosorbants are required. Already at this early stage, however, it seems that autoimmune reactions can be used in a productive manner to manipulate the immune system in the transplantation immune system, in allergic disorders and perhaps even to regulate the course of certain autoimmune diseases.

Induction of transplantation tolerance using serum as antigen source

It has been shown that massive doses of allogeneic serum produce the prolongation of renal allograft survival in adult pigs[1]. Furthermore, alloantigenic activity was demonstrated in human serum by inhibiting certain reactions *in vitro*[2–6]; and in some strains of mice, the presence of histocompatibility (H) antigens in the serum could be demonstrated by inhibition of the cytotoxicity of specific alloantisera[7].

This study was designed to determine whether transplantation tolerance in rats can be induced by multiple massive doses of serum. Rats of the AVN strain were injected with allogeneic or syngeneic serum in increasing doses three times weekly from birth to the 6th week of age (1st week, 3×0.3 ml; 2nd week, 3×0.5 ml; 3rd week, 3×1 ml; 4th and 5th weeks, 3×1.5 ml; 6th week, 3×2 ml). The donors of allogeneic sera were rats of the congenic strains Lewis (Lew) or Lew.1A, differing from the AVN strain recipients in, respectively, both H–1 plus non-H–1 antigens and in the non-H–1 antigens only. Four weeks after birth, animals were skin grafted. The group treated with Lew serum, the control groups treated with AVN serum and the group of untreated animals simultaneously received the

Fig. 1 Survival of Lew.1A skin grafts after treatment with Lew.1A serum (●). AVN serum (○), untreated controls (△).

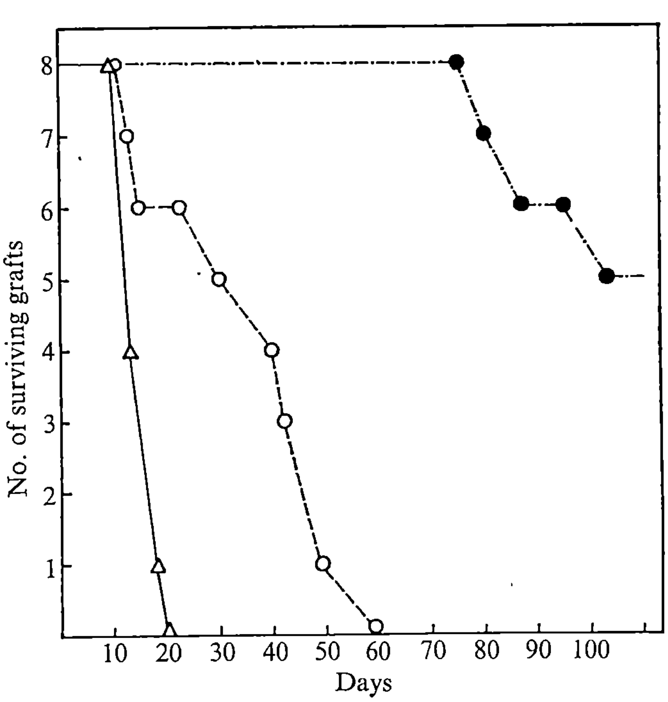

Table 1 Testing of AVN anti-Lew cytotoxic antibodies in AVN rats injected with Lew or AVN serum from birth

Group	Treatment	Serum titre*	Percentage ^{51}Cr release±s.e.†
1	—	1:8–1:64	28 8±4.7
2	AVN serum	1:8–1:128	37.0±12.6
3	Lew serum	–	15.5±1.9‡

*The cytotoxic activity of the serum was determined by the ^{51}Cr release from labelled lymphocytes of the strain Lew by the standard technique[8]. The cytotoxic titre was determined as the highest serum dilution showing significantly higher ^{51}Cr release than a similar dilution of normal serum.

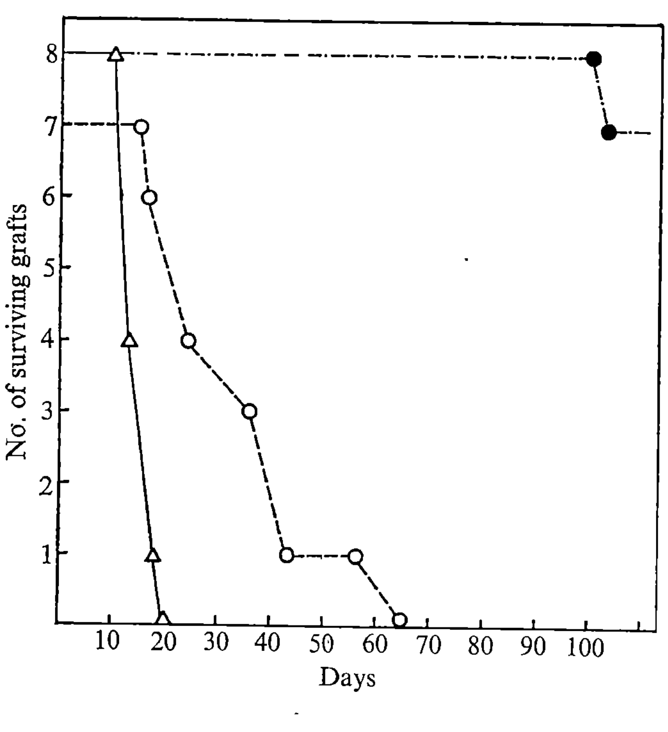
†Percentage of released activity with a 1:1 dilution of serum.

‡Statistically significant ($P < 0.001$) inhibition of cytotoxic antibody production in comparison with group 1 or group 2 and non-significant difference from the value of ^{51}Cr release in the tests of serum from normal untransplanted rats (13.1±0.3%).

Lew and Lew.1A skin grafts. The group treated with Lew.1A serum and the corresponding control groups received only Lew.1A skin grafts.

A high degree of tolerance was obtained in the animals with the non-H–1 antigenic difference. Figure 1 shows the survival of skin grafts in animals treated with Lew.1A serum. All grafts survived 75 d and most of them more than 100 d. In addition to the specific antigenic activity of the serum, its nonspecific component(s) had some effect, as evident from the prolongation of skin graft survival in the control animals treated with syngeneic serum. Also, the Lew serum induced a high degree of tolerance of non-H–1 different Lew.1A grafts (Fig. 2). All these grafts survived 100 d and most of them persisted further. Again the nonspecific effect of the syngeneic serum was evident in the ability to prolong the Lew.1A skin-graft survival. With the H–1 plus non-H–1 antigenic difference (Fig. 3), skin grafts in two of eight animals had significantly prolonged survival times; the nonspecific effect of the serum was not at all apparent. In this group of animals, the possible presence of cytotoxic H–1 antibodies was also investigated. Serum samples were collected 17 d after skin grafting for the cytotoxicity test[8]. In comparison with the untreated controls (Table 1, Group 1) and Group 2 given syngeneic AVN serum, the Group 3 animals treated with Lew serum showed complete inhibition of anti-Lew antibody production.

Fig. 2 Survival of Lew.1A skin grafts after treatment with Lew serum (●), AVN serum (○), untreated controls (△)



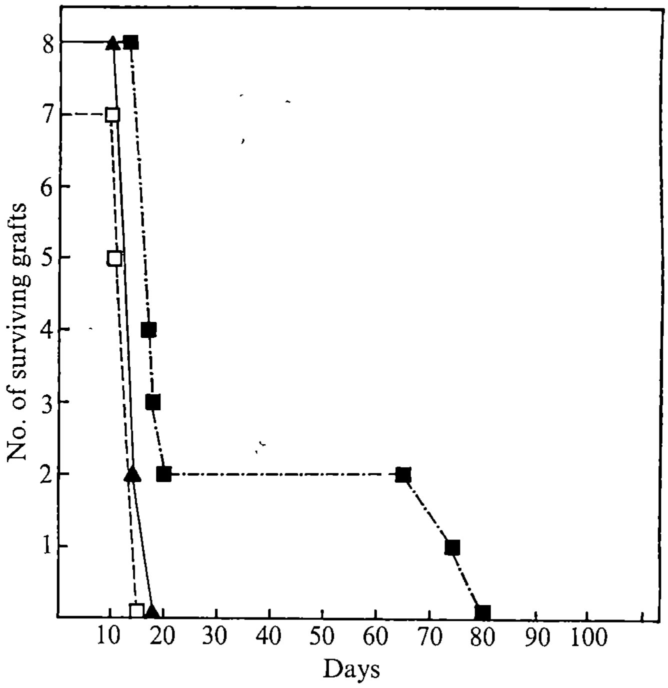


Fig. 3 Survival of Lew skin grafts after treatment with Lew serum (■), AVN serum (□), untreated controls (▲).

In spite of the presumably low content of antigens in the serum, permanent tolerance of skin grafts can be induced in rats, at least in the non-H–1 incompatible combination. The antigenic difference between the donor and recipient strains is relatively strong, as shown by the acute rejection of skin grafts in untreated controls. With the H–1 plus non-H–1 difference, the degree of tolerance achieved is considerably lower. This does not, however, exclude the possibility that it can be increased by concentrated antigen from the serum. The nonspecific immunosuppressive effect of normal serum on non-H–1 incompatible skin grafts is consistent with previous findings[9–14]. To summarise the present data, it seems that the serum may be a very good source of soluble H antigens useful for the induction of transplantation tolerance.

●

Antibody response induced *in vitro* to the cell-surface alloantigen Thy–1

MANY important antibody responses are provoked by antigens on the surfaces of nucleated cells and, in spite of wide interest, little is known of the immunobiology of these responses. Alloantigens comprise an intriguing class of surface antigens because they may stimulate antibody production by B cells as well as target-cell killing by T cells and also because alloantigens are themselves intimately involved in the immunological recognition of other cellular antigens, such as viral antigens[1], autoantigens[2], surface-bound haptens[3], other alloantigens[4] and tumour-associated antigens[5]. Studies of antibody responses *in vitro*, involving potent xenoantigens, have contributed greatly to the understanding of cellular and molecular interactions in immunity[6]. This has suggested the potential of such systems for the study of responses to weaker antigens of nucleated cells. In this report I define such an experimental approach with the induction *in vitro* of primary and secondary responses to the murine alloantigen Thy–1 as measured with a modified plaque-forming cell (PFC) assay, developed from the method of Fuji *et al*[7].

Thy–1 is present as two allelic variants, Thy–1.1 (strain AKR) and Thy–1.2 (CBA)[8], and is expressed in high density at the surface of thymic lymphocytes which serve as target cells in the PFC assay. In initial experiments the induction of a response to Thy–1 was attempted by coculturing normal or primed AKR spleen cells with antigen in the form of viable CBA thymocytes. Very few PFC lytic to CBA thymus cells appeared although the duration of culture and cell ratios were varied. By contrast, the use of a cell-free supernatant of thymocyte cultures induced substantial PFC responses. A comparison of the ability of thymus cells and supernatant to induce a primary response is shown in Table 1. CBA but not AKR thymocyte supernatants (AKR-T-SN) induced the production of PFC from AKR spleen cells, at an optimal dilution of antigen of 1/15. Addition of CBA thymocytes to spleen cell cultures failed to generate PFC although they were present in numbers consonant on the concentrations of cells which yield immunogenic supernatants (2.5×10^6–5.0×10^6 ml^{-1}). In the absence of antigen, no PFC are detected in primary responses. Figure 1 illustrates the specificity of the primary response and also follows the response kinetics which show a maximum at 4 d. Later peak responses (5–6 d) have been found in other experiments. The AKR-T-SN, which fails to stimulate AKR spleen cells, can stimulate large anti-AKR PFC responses of CBA spleen cells (optimal dilution 1/10–1/25, data not shown). Reciprocity of the response, however, does not prove immunological specificity since it is possible that allogeneic supernatants simply induce polyclonal PFC responses. Further evidence for specificity was obtained through the use of third-party thymus supernatants derived from the congenic strains A/Thy–1.1 and A/Thy–1.2. Titrations of the immunogenicity of A/Thy–1.1-T-SN and A/Thy–1.2-T-SN paralleled precisely those of AKR-T-SN and CBA-T-SN, respectively (unpublished results). Since both A/Thy–1 strains have numerous alloantigens absent in AKR which excepting Thy–1.2, fail to induce PFC, it follows that the induction of PFC is antigen specific and attributable fully and exclusively to the Thy–1 antigen.

Secondary *in vitro* responses of AKR spleen cells from mice immunised *in vivo* with CBA thymocytes differ from primary responses in kinetics and in optimal antigen dose. The secondary response exhibits a sharp peak at 3 d and the optimal concentration of supernatant antigen is about 1/10 of that optimal for generating primary responses; an example of a secondary response is shown in Table 2. In this experiment the specificity of induction is evident, as AKR-T-SN produced only few PFC above a small background now detected in the absence of added antigen.

Although an antigenic difference at the Thy-1 locus induces the PFC response and other alloantigens fail to do so, it was possible that Thy–1 substance acted nonspecifically to augment immunity to another alloantigen or autoantigen and that the PFC response was not directed at Thy–1. This was examined by testing one pool of AKR anti-CBA PFC against a panel of thymus cells from strains AKR, A/Thy–1.1, CBA and A/Thy–1.2. Mean PFC per group on day 3 was 0, 0, 143, and 134, respectively, which rules out the possibility of autoantibody

AKR 5.0×10^5	4±2.3	AKR 1:15	10±2.0
AKR 1.0×10^5	1±1.0	AKR 1:75	2±0.3
		AKR 1:150	3±1.3

A modified Marbrook culture system was used[6] in which 15×10^6 spleen cells, in 1 ml of appropriate medium were placed into the inner dialysis compartment and 15 ml of Eagle's modified minimal essential medium (MEM) containing 5% newborn calf serum (MEM-CA_5) and 2-mercaptoethanol (5×10^{-5} M) were added to the outer flask. Thymocyte culture supernatant was prepared by cultivating thymocytes (62.5×10^6 ml^{-1}) in Dulbecco's modified MEM (E4) containing 10% foetal calf serum (E4-F_{10}) for 20 h at 37 °C in 10% CO_2 and air and collecting the supernatants by centrifugation at 250*g* and passage through a Millipore membrane (0.22 µm). PFC assays were based on the method of Fuji *et al.*[7], and modified to accommodate a Trypan blue staining routine[11]. Briefly, aspirated cultures were collected into pellets by centrifugation at 100*g* for 15 min and 0.05 ml of a 12% suspension of appropriate thymocytes (in MEM-CA_{10}) was added. The tubes were then warmed to 37 °C to receive 0.35 ml of 0.6% agar in E4-CA_{10}, the latter maintained at 45–50 °C. After mixing, the suspension was applied to the surface of a 50-mm Petri dish containing 1–2 ml of solid 1% Agarose (Induboise A37, L'Industrie Biologique Francaise, Gennevilliers) in phosphate-buffered saline (PBS). After gelation, 3.0 ml of E4-CA_{10} was added to each of the dishes which were then incubated at 37 °C for 3.5 to 4.5 h. Each dish then received 1.5 ml of complement (rabbit serum absorbed with mouse spleen cells) diluted 1:15 in E4-CA_{10}. After further incubation for 0.75 h the dishes were drained and stained with 1.5 ml of 0.2% Trypan blue for 20 min at 20 °C. The dishes were rinsed with PBS and the plaques were counted using a dissecting microscope (Baush and Lomb, ×10) adjusted for diffuse indirect illumination. In these experiments normal AKR spleen cells were suspended in 1 ml of various dilutions of thymocyte supernatant in E4-F_{10} or in E4-F_{10} containing various numbers of thymocytes, which were then added to the inner culture chamber. Triplicate or quadruplicate cultures were assayed for PFC after incubation for 4 d at 37 °C in a humid 10% CO_2–90% air atmosphere.

Table 2 Specificity of the induction of a secondary anti-Thy-1 response *in vitro* of AKR spleen cells by antigenic supernatants of thymocytes

AKR supernatant antigen (AKR-T-SN)	PFC per culture (±1 s.e.m.)	CBA supernatant antigen (CBA-T-SN)	PFC per culture (±1 s.e.m.)
1:25	33±19.7	1:50	198±9.5
1:125	(1) 21±7.0	1:125	(1) 340±60.0
1:500	17±9.6	1:500	166±61.9
		1:1,500	55±8.7
Medium alone	12±5.2	1:5,000	7±3.7

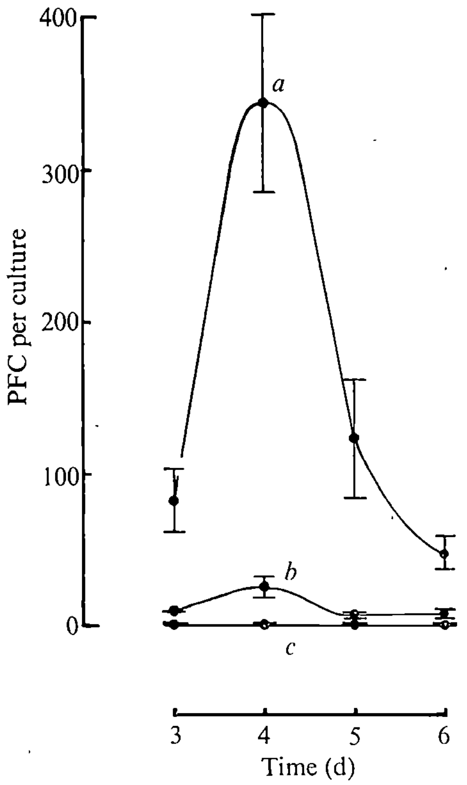
Cultures were assayed after 3 d for PFC. For priming, AKR mice received 4×10^7 CBA thymus cells intravenously 2–8 weeks before use The data were obtained with CBA target cells in the PFC assay; figures in parentheses are the mean autoantibody PFC per culture detected with AKR thymus cells as targets using portions of the same cultures

production and shows that virtually all the *in vitro* secondary alloantibody PFC produce anti-Thy-1 antibody. Primary response PFC, however, do contain an interesting subpopulation (10–20%) of autoantibody PFC.

These experiments demonstrate that alloantibody responses to a surface antigen of nucleated cells can be induced entirely *in vitro*. Both primary and secondary responses are produced, the latter with *in vivo* primed spleen cells, and are shown to differ in kinetics and in sensitivity to antigen. In contrast with *in vivo* PFC responses, which are induced on challenge with viable thymus cells (ref. 7 and my unpublished results), the *in vitro* responses are induced only with antigenic supernatants of cultured thymocytes. A rapid appearance of immunogen (⩽ 4 h) in culture supernatants was found in preliminary studies consistent with the release of Thy-1 antigen from thymocytes detected by Vitetta *et al.*[9]. Therefore, the failure of thymus cells to stimulate PFC cannot be ascribed to a late release of antigen and is the subject of a study in progress. Preliminary experiments involving gel filtration indicate that the cell-free immunogen is much larger than molecular Thy-1; it therefore probably comprises Thy-1 in association with other surface molecules. The contribution of the latter to the immunogenicity of Thy-1 remains to be determined.

This experimental system, more generally, permits access to some basic problems of cell-surface immunogenicity, such as interactions among distinct surface molecules, the handling and presentation of antigen, the role of T cells and the determinants they recognise, control mechanisms of the response and the possibility of a rational approach to the manipulation of the response[10]. In this respect, cell-surface antigens in autoimmunity, and those of viral and tumour origin are interesting candidates.

Fig. 1 Kinetics and specificity of a primary anti-Thy-1 PFC response to CBA target cells induced *in vitro* with AKR spleen cells stimulated by thymus cell culture supernatant. *a*, Response to CBA supernatant diluted 1:25; *b*, response to AKR supernatant diluted 1:25; *c*, response to medium alone. Vertical bars represent ±1 s.e.m.



I thank Professor N. A. Mitchison for advice, Dr D. C. Parker for assistance and suggestions, Dr Elizabeth Simpson for congenic mice, and Juliet Strang for technical help. I thank the MRC of Canada for a postdoctoral fellowship.

Transition probability and the hormonal and density-dependent regulation of cell proliferation

WE have recently been studying cultured cells derived from the androgen-responsive mouse mammary tumour, Shionogi 115 (S115)[1,2]. Here we show, from time-lapse cinemicrographic analysis of these cells, that regulation of proliferation rates by both cell population density and physiological concentrations of testosterone is achieved by changes in 'transition probability'.

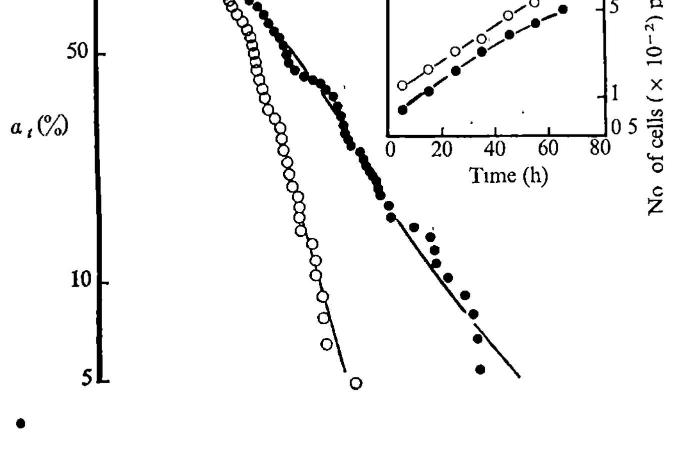
It is increasingly apparent that cell division depends on the occurrence of a random transition in G_1 (refs 3–5). On this basis, a model of the cell cycle has been proposed which also quantitatively accounts for the observed heterogeneity of cell cycle times within cell populations[3]. According to this model, the cell cycle is divided into two parts; one called the B phase where cells are proceeding towards division, and the other called the A state, where cells are not proceeding to division but are 'waiting' for a random triggering event to occur before proceeding. A cell may remain in this A state for any length of time and it has been shown that in steady-state conditions, the cell has a constant probability per unit time ('transition probability') of leaving the A state and entering the B phase[3]. It is thought that cells enter the A state in the G_1 phase of the cell cycle because the kinetics of entry of cells into the S phase are identical with the kinetics of entry into division[6]. The B phase then comprises part of G_1, and S, G_2 and M phases of the 'classical' cell cycle. The A state has much in common with the conventional G_0 in that cells in 'A' or 'G_0' are not proceeding towards division. Although G_0 is often regarded as a kind of refuge into which a fraction of cells can retreat when conditions are unfavourable for proliferation, all cells are supposed to enter the A state in every cell cycle, irrespective of their proliferation rate. Even optimally growing transformed fibroblasts enter the A state and then have a given transition probability of leaving and progressing to DNA synthesis and division.

According to the model, proliferation rates could be changed by altering either the duration of B phase (T_B) or the transition probability, or both. There is evidence that proliferation rates of animal cells are regulated in the main by changes in transition probability (P) rather than by changes in T_B (refs 4 and 5).

S115 cells are particularly interesting because physiological concentrations of testosterone have two distinct, reversible effects on the cells. First, at any density, testosterone stimulates the proliferation rate approximately twofold. Second, cells seeded in the presence of testosterone grow exponentially and fail to exhibit density-dependent regulation of proliferation rate until high densities (0.3×10^{6} cells cm^{-2}) are reached, whereas cells seeded in the absence of the hormone proliferate in a density-regulated manner; that is, proliferation rate decreases continuously over a wide range of increasing densities. Thus the phenomenon of density-dependent regulation of proliferation rate may be studied by comparing the behaviour of cells grown either in the presence or absence of a known, purified hormone.

Generation times of S115 cells growing in modified Eagle's medium have been analysed by time-lapse cinematography. The data is plotted as the logarithm of the percentage of undivided cells against age (Fig. 1). This type of curve is an α curve, (where α_t is the percentage of cells with intermitotic times $\geqslant t$)[3]. In an ideal population of cells having identical durations of B phases (T_B) and identical transition probability, α_t remains at 100% for ages up to T_B, then declines exponentially at a rate determined by the transition probability. It has been shown[3] that in steady-state cultures α curves exhibit initial curvature, produced by variability in the length of the B phase (T_B), followed by an exponential tail. The shortest intermitotic time gives the value of the minimum T_B, whereas the point at which the α curve becomes linear gives the maximum T_B. If a given treatment were to change T_B and not P, then the α curves for the treated and untreated populations would be parallel but laterally displaced from each other along the abscissa. Conversely, a change in P and not T_B would produce two lines with different slopes, but the same origin on the abscissa. It can be seen in Fig. 1 that the origins of the two curves for testosterone-treated and untreated cells are similar and the slopes of the exponential tails of the α curves are different, indicating that the minimum T_B is unchanged, but transition probability is different in each case.

Fig. 1 Semi-logarithmic plot of % cells undivided at age t (α) against t for S115 cells. S115 cells were cultured in Dulbecco's modified Eagle's medium containing 2% foetal calf serum and 30 mM HEPES as described previously[6]. Testosterone (T), when added, was present at 3×10^{-8} M. Exposures were made at 3-min intervals and individual intermitotic times measured by frame-by-frame analysis. The time of mitosis was taken when the cell rounded up before division. Number of observations = 93 for +T, 91 for −T. ○, + testosterone, ●, −testosterone. Inset, increase in cell number during the course of the filming.



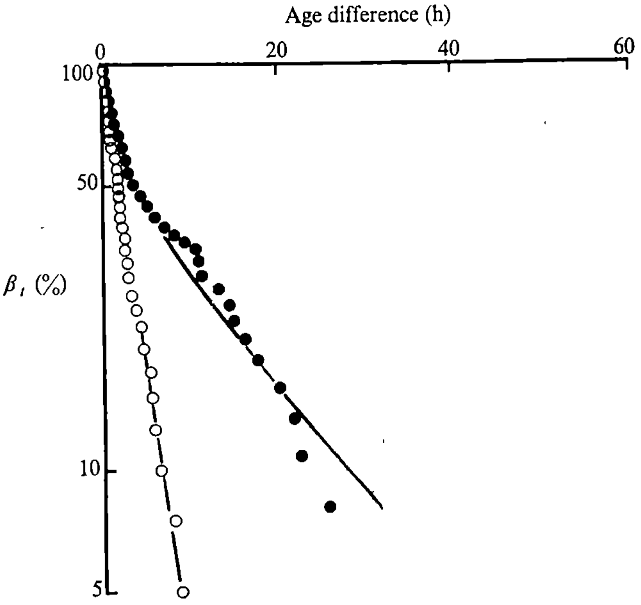


Fig. 2 Semi-logarithmic plot of % of sibling pairs with differences in intermitotic time > t (β) against t for S115 cells. Data were taken from the same film as Fig. 1. Number of sibling pairs = 40 for +T; 43 for −T. Symbols as Fig. 1.

Calculation of transition probability from the α curve is subject to some error since it is difficult to detect exactly when the initial curvature finishes. It has been shown that the differences in sibling intermitotic times can be used to give a better estimate of transition probability[4] because, in steady-state cultures, differences in intermitotic times of sibling cells are due entirely to differences in the times they spend in A state, their B phases being of identical duration[7]. The data in Fig. 2 are plotted on semi-logarithmic axes, giving a so-called β curve (where β_t is the percentage of sibling pairs with differences $\geqslant t$)[7]. Theoretically, β curves should yield a straight line plot if cells are growing exponentially, but not otherwise. Indeed this was found to be the case; the β curve for the exponentially growing, testosterone-treated cells gave a straight line, and that for the untreated cells curved upwards. The curvature indicates that transition probability is variable in the untreated cultures. To test whether this variability was a function of density, the data for sibling differences of the untreated cells were split into two groups on the basis of the time of division of the parent cell (Fig. 3). One group represents early divisions of the parent cell (less than 15 h after the beginning of the time-lapse film), whereas the other group represents later divisions (more than 15 h). The data in Fig. 3 show that the β curve of sibling cells dividing at later times is less steep than that of cells dividing at early times; that is, the mean transition pro-

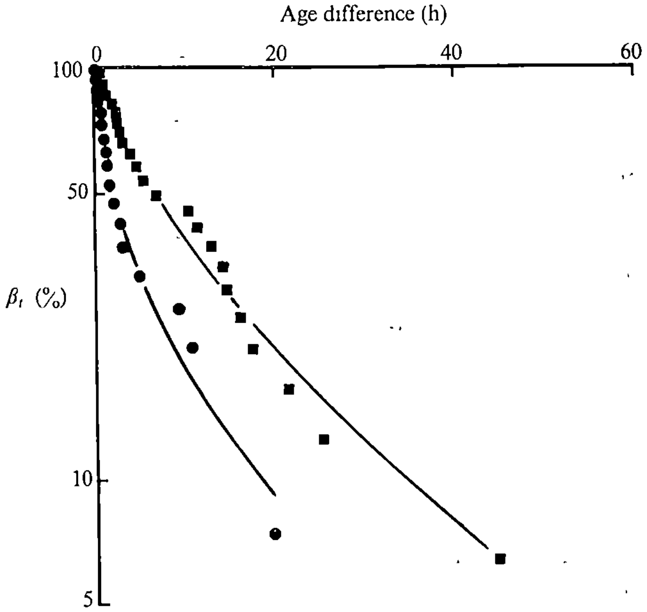

Fig. 3 Semi-logarithmic plot of β against t for two groups of the untreated cells ●, Analysis of siblings derived from parent cells which divided in the time interval 0–15 h from the beginning of the film. ■, Analysis of siblings derived from parent cells which divided at times > 15 h. Number of sibling pairs in the first group = 19; in the second group = 24

bability of later dividers is less than that of early dividers. Furthermore, both curves still display marked curvature, indicating that transition probability decreases continuously with density. In addition, α curves of the two groups demonstrated that there was little, if any, change in T_B with density (not shown).

In conclusion, both testosterone and cell population density affect proliferation rate by changing transition probability; both have little effect on the B phase of the cell cycle. The transition probability model may be successfully applied to non-steady-state cultures as well as to cultures growing exponentially.

Identification of the cell multiplication inhibitory factors in interferon preparations as interferons

THERE has been some controversy for the past few years concerning the inhibitory effect of interferon on cell multiplication We and others have presented evidence that interferon itself is the responsible factor[1-13]. Some investigators have, however, failed to observe any inhibition of cell multiplication with interferon preparations[14-17]; while others have observed inhibition but ascribed this effect to substances other than interferon in their preparations, either because no inhibition was observed when more purified preparations were used[18] or because of apparently inconstant ratios between antiviral and cell multiplication inhibitory (CMI) activities in a given preparation[19-21]. It has been claimed that the factor responsible for the CMI activity of human leukocyte interferon preparations could be physically separated from the factor responsible for the antiviral activity[22]. We provide strong evidence that the antiviral and CMI activities of interferon preparations are indeed intrinsic properties of the covalent structure of interferons.

Human[23] and mouse[24] interferon preparations can be reactivated after being unfolded under denaturing conditions in hot sodium dodecyl sulphate (SDS), a procedure which dissociates all non-covalently linked molecules[25] The finding that the antiviral activity of interferon can be recovered after such treatment has enabled the separation and identification of distinct molecular forms of both mouse[26,27] and human[28] interferons by electrophoresis in SDS–polyacrylamide gels. Accordingly, in our experiments human leukocyte and mouse C-243 cell culture interferon preparations were boiled in the presence of SDS, either in non-reducing or reducing conditions, were subjected to electrophoresis in SDS–polyacrylamide gels, and gel fractions tested for antiviral and CMI activities

The human leukocyte interferon preparation, electrophoresed after boiling in SDS in non-reducing conditions, contained two peaks of antiviral activity, one at about 21,000 daltons and one at approximately 15,000 daltons (ref 28 and Fig. 1*a*). The two peaks of antiviral activity coincide with the distribution of the CMI activity; there is a very good quantitative correlation between the antiviral activity and the CMI activity of each of the gel fractions.

When human leukocyte interferon was boiled in the presence of mercaptoethanol there was a loss of antiviral activity of the 15,000-dalton component, with only partial loss of the antiviral activity of the 21,000-dalton component (ref. 28 and Fig. 1*b*). Likewise, CMI activity was present in the 21,000-dalton component and markedly decreased or absent in the 15,000-dalton component (Fig. 1*b*).

Unreduced mouse C-243 cell interferon exhibited a major peak of antiviral activity at an apparent molecular weight of 38,000 and a minor peak at about 22,000 (Fig. 2*a*). Thus, these mouse interferon preparations are similar in molecular heterogeneities to mouse interferon preparations produced in L-929 cells induced with Newcastle disease virus[26] and in Lpa cells induced with MM virus[27]. There was a direct quantitative correlation between the antiviral and CMI activities in the regions of the two peaks (Fig 2*a*) Also when C-243 cell interferon was boiled in reducing conditions and electrophoresed in SDS–polyacrylamide gels, there was again a direct quantitative correlation between the two activities (Fig. 2*b*) and neither activity was present at 22,000 daltons.

In other experiments, gel eluates were assayed for both antiviral and CMI activities in cultures of $L_{\text{u-10}}$ cells, which were as sensitive as L-929 cells to the antiviral activity of mouse interferons and were approximately as sensitive as the L-1210 cells to the CMI activity of mouse interferon preparations. As in the experiments just described, the profiles of the two activities could be virtually superposed Also, it was found that about 1% of both the antiviral and CMI activities of human leukocyte interferon crossed on mouse $L_{\text{u-10}}$ cells. When these mouse cells were used to assay gel eluates of electrophoresed human leukocyte interferon preparations, activity profiles were obtained for both antiviral and CMI activities which correlated with those found in human cell assays, with each fraction being active in the mouse cells at about 1% of its activity in human cells.

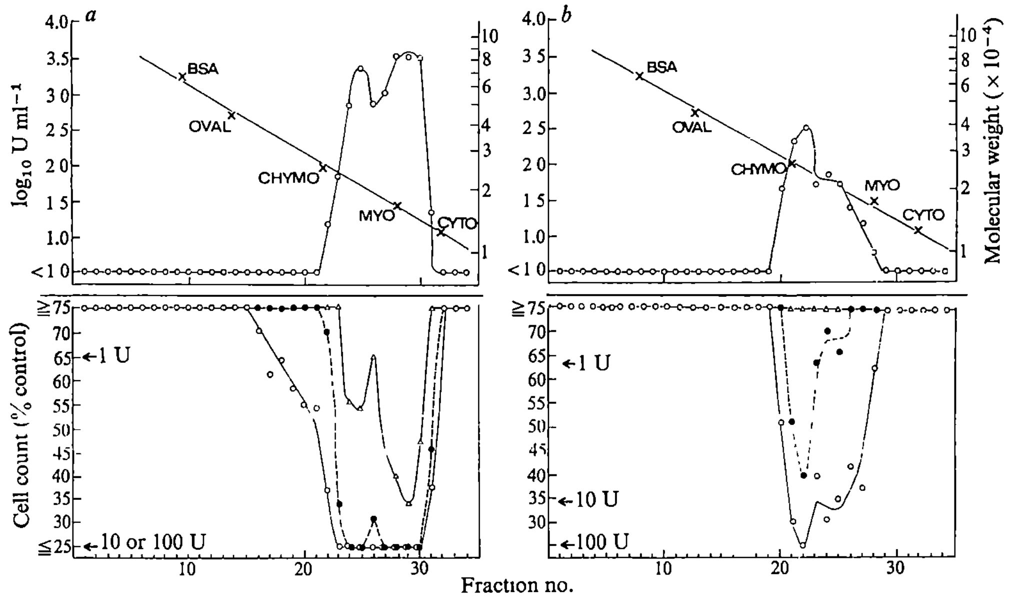

Fig. 1 SDS-polyacrylamide gel electrophoresis of human leukocyte interferon assayed for antiviral and CMI activities in non-reducing (*a*) and reducing (*b*) conditions. *a*, Human leukocyte interferon induced by Sendai virus[29] containing approximately 10^6 U (human standard reference 69/19) and 2.5 mg protein per ml in 0.01 M phosphate buffer, *p*H 7.2 was constituted to contain 1% SDS and 5 M urea and was boiled for 1 min. An aliquot of 0.1 ml was applied to the gel and, following electrophoresis, 5-mm gel fractions were eluted in 2 ml Eagle's MEM containing 10% calf serum. Conditions for electrophoresis were as described previously[26]. Upper panel: antiviral activity was assayed on human diploid skin fibroblasts challenged with vesicular stomatitis virus (VSV). BSA, bovine serum albumin; OVA, ovalbumin; CHYMO, chymotrypsinogen; MYO, myoglobin; CYTO, cytochrome *c*. Lower panel: CMI activity was assayed on Burkitt lymphoma cells (Daudi line)[30]. All gel eluates were incubated with 5×10^4 Daudi cells per ml in 2 ml RPMI medium containing 10% foetal calf serum, and cell multiplication was determined after 3 d incubation by counting viable cells in an haemocytometer using the Trypan blue exclusion test. Native human leukocyte interferon at 1, 10 and 100 U ml^{-1} was used as reference. All eluates were tested at a 1:10 dilution (○) and, where indicated, at a 1:100 (●) or a 1:1,000 dilution (△). All points are averages of duplicate determinations. *b*, The same human leukocyte interferon preparation was constituted to contain 1% SDS, 1% mercaptoethanol and 5 M urea and was boiled for 1 min before application to gel.

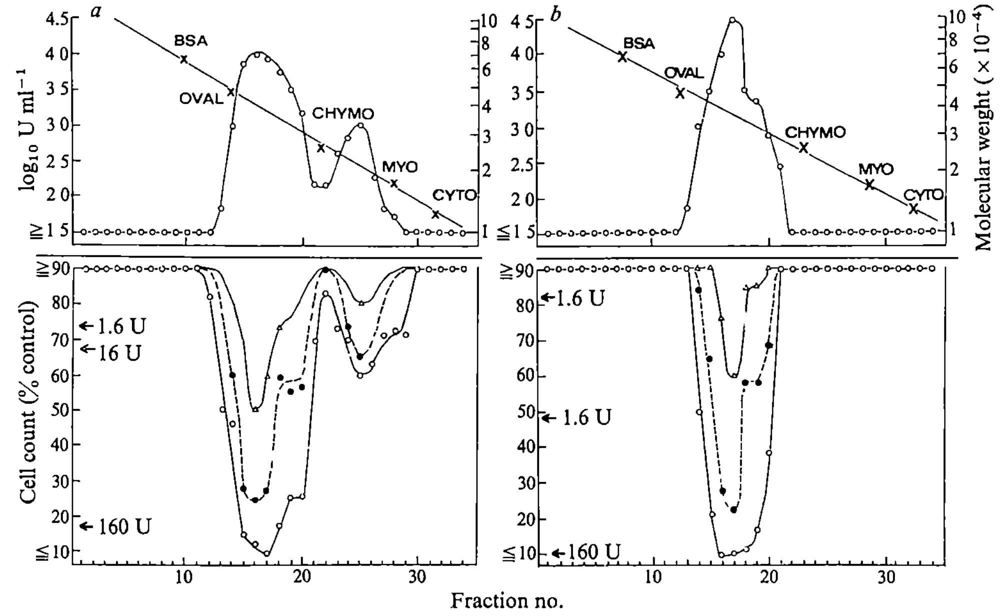

Fig. 2 SDS-polyacrylamide gel electrophoresis of mouse C-243 cell interferon assayed for antiviral and CMI activities in non-reducing (*a*) and reducing (*b*) conditions. *a*, Mouse C-243 cell interferon induced by Newcastle disease virus[31] containing approximately 3×10^6 U and 1 mg protein per ml in 0.01 M phosphate, *p*H 7.2, was constituted to contain 1% SDS and 5 M urea and was boiled for 1 min. An aliquot of 0.1 ml was applied to the gel and, following electrophoresis, fractions were eluted as in Fig. 1. Upper panel: antiviral activity as assayed on mouse L cells challenged with VSV[31]. Lower panel: CMI activity was assayed on mouse leukaemia L-1210 cells[2]. All gel eluates were incubated with 5×10^4 L 1210 cells ml^{-1} in 2 ml RPMI medium containing 5% horse serum, and cell multiplication was determined after 3 d incubation by counting viable cells in an haemocytometer using the Trypan blue exclusion test. Native mouse interferon at 1.6, 16, and 160 U ml^{-1} was used as reference. All eluates were tested at a 1:10 dilution (○) and, where indicated, at a 1:100 dilution (●) or at a 1:1,000 dilution (△). All points are averages of duplicate determinations. *b*, The same mouse C-243 cell interferon preparation was treated in the same reducing conditions as in Fig. 1*b*, before application to gel.

The direct quantitative correlation between the antiviral and CMI activities of both human leukocyte and mouse C-243 cell interferons—(after boiling these interferons in SDS and subjecting them to electrophoresis in SDS-polyacrylamide gels)—shows that the CMI activity is exerted by molecules with heterogeneities of the same size as those of the interferons in the preparations. Furthemore, as there were two peaks of activity for unreduced human leukocyte (21,000 and 15,000 daltons) and mouse interferon (38,000 and 22,000) the CMI factor is present in exactly the same proportion as the interferons of each of those sizes. Therefore, either both activities reside in the covalent structure of the same molecules (interferons), or there are two distinct populations of molecules that induce antiviral activity and two distinct populations of molecules, of the same two sizes and present in the same relative proportions as the two interferon populations, that induce CMI activity. Furthermore, in the case of human leukocyte interferon, each of these populations responsible for CMI activity, like the interferons, exert only ~ 1% of homologous activity in heterologous cells. The finding that the correlation between the two activities is unchanged when these interferons are boiled in reducing conditions and electrophoresed in SDS, indicates not only that the two activities reside in physically similar molecules (in terms of size heterogeneities) and are present in the same proportions, but that they are also due to chemically similar molecules (in terms of effects of reduction of disulphide bonds in detergent solution).

We thank Dr Kari Cantell for human leukocyte interferon and the Philippe Foundation for their help. W.E S., II was supported by EMBO. This work was aided in part by grants from the Del Duca Foundation and the Direction de Recherches et Moyens d'Essais.
